Vol. IV Pawtucket, R.I., January, 1913. No. 1

G. V. ELECTRIC TRUCKS AT THE NEW YORK SHOW

The General Vehicle Company, Inc., will have the largest space (A 38), and the largest exhibit in the Grand Central Palace section of the New York Auto Show, January 20th to 25th inclusive, and will exhibit the following:

1000 lb. Wagon, Zampieri Brothers, Bakers.
2000 " " Otto Stahl, Butcher.
2000 " Industrial Truck.
2-ton truck, Wells Fargo Express Co.
2-ton G. V. Chassis.
3 1-2 ton truck, Beadleston & Woerz, Brewers, (Panel side bottle truck)
5-ton " Jacob Ruppert, Brewer, (Screen side bottle truck)
5-ton " Jacob Ruppert, Brewer, (Low seat keg type)

These machines are all regular trucks and wagons going through the factory, but behind each one there is an interesting story.

Zampieri Brothers' little wagon represents a **horseless delivery system** for bakers. (All horses sold in 11 months, and 4 G. V. Wagons substituted). Otto Stahl has ordered 3 G. V's. in a year. The Wells Fargo Truck is something different in body lines and so is the Ruppert screen body truck.

Don't fail to see the G. V. Exhibit.

THE NEW YORK MOTOR TRUCK SHOWS.

THE realization of the economic possibilities of motor vehicles is revolutionizing highway transportation, and because of this fact the exhibition of service wagons and trucks to be made at Madison Square Garden and Grand Central Palace, New York City, Jan. 20-25 inclusive, is of vast importance. While the displays will be worth the attention of any person from an educational point of view, as factors in business education they cannot be over-estimated. The cost of haulage and handling reaches enormous sums annually. The economy cannot be a result of system and co-operation and must be undertaken individually by the person or concern interested. Each problem differs from another because of conditions which cannot be controlled, and each must be worked out according to the resources and circumstances of those directly concerned.

Col. George Pope, Chairman, A. B. of T. Show Committee.

The service wagon shows will be of special and enduring value to each visitor. They will attract thousands who will hope to benefit through the information that may be gathered and the knowledge that may be applied in daily industrial and commercial life. They will have opportunity to study the differing forms of vehicles and the constructions created for general and special purposes, and to learn of the adaptations of the machines to meet the requirements of those who may be purchasers.

The service wagon canot be regarded as experimental other than in the sense of not being used generally. Its value has been proven beyond all question. It must be utilized, not with a purpose of merely supplanting animal transports, but as a means of economizing from every possibility. It has the same relation to road transportation that the telephone has to the telegraph, that express service has to the freight, that the trolley car has to the animal track vehicle. It is not to be assumed that the industrial conveyance has been perfected, but it will be admitted that there has been a marvelous development, which is due to the understanding by business men of the economic possibilities, although these have not been realized.

Demand has created the quality of practically every utility the world enjoys. The vehicles in use in America are numbered by millions. Estimates of the motor wagons now in service widely differ because there are no actually dependable figures, but it would seem that 50,000 is a conservative total. There are hundreds of types, and these have been produced with, as a rule, the idea of specializing the needs of those who would seem so numerous as to afford a separate and distinct market. There are today in the United States more than 200 different vehicle builders who are recognized in the industry as producing machines commercially, and there are nearly 100 other firms and individuals building and experimenting with the purpose of becoming as active factors as resources and the merit of their products will permit. In many instances the makers produce both pleasure and service vehicles, and there is a large proportion of manufacturers who devote themselves to the latter type.

Grand Central Palace, New York City, Where a Division of the 1913 Motor Truck Show Will Take Place.

The New York shows, which will be held Jan. 20-25, inclusive, in Madison Square Garden and Grand Central Palace, will be made up of the displays of 67 different manufacturers. Those who will visit the one exhibition building will hardly feel that they have satisfied their desire for information, unless the purpose is to examine a single or few machines, and it may be said that practically all visitors will see the productions of leaders of the industry. The exhibits will range from a single machine to perhaps a dozen, and

Madison Square Garden, New York City, Where a Division of the 1913 Motor Truck Show Will Take Place.

these will be the latest and most improved designs produced. It is not too broad a statement to make to place the probable total number at 350, and it is quite as probable that these will represent not far from 200 different sizes or types. There will be 25 makers having exhibits at the Madison Square Garden, and all of these will be gasoline vehicles. At Grand Central Palace 33 makers of gasoline machines will make display, and nine builders of electric wagons and trucks.

At the former exhibition building will be the stands of the older manufacturers, most of whom will have the same spaces they occupied with showings of pleasure cars, while at Grand Central Palace will be the exhibits of those who either build service vehicles exclusively, or are specially developing this division of their business. Here will be seen some of the latest machines and some that have never before been exhibited in the East. There will be more new productions at this building than at Madison Square Garden, and in addition there will be the best and most recent designs turned out by the leading builders of electric wagons and trucks.

Alfred Reeves, A. B. of T. Show Committee.

The Madison Square Garden show will be especially interesting from the fact that it will reflect the progression and development of the makers whose experience has been exceedingly broad, whose vehicles may be said to represent the industry, and have been perfected from the knowledge of actual service. There will be few radical machines shown by them. There will be new Buick wagons, shown for first time; the new water-cooled flexible chassis Kelly machines, the new Reo and the new Hupmobile wagons, while of course there will be additional types of some of the builders familiar to the industry.

At Grand Central Palace will be seen the new Blair, Brown, Gramm-Bernstein, Stewart and Standard machines, and new types developed in Chase, Rowe, Sanford and Schacht vehicles, while the Buffalo electric wagon will be seen for the first time. The electrics will be departmentalized, an innovation in metropolitan shows. There will be a number of vehicles of special interest in that the worm drive has been adopted, this being true of the new Rowe and Schacht wagons, and the Manly drive will be seen on the La France trucks to be shown by the Hydraulic Truck Sales Co. There will be innumerable adaptations and installations to convenience operation and economize in time, and a number of machines will be shown with starting devices.

The one feature that will appeal to all will be the special bodies built to meet the requirements of different forms of haulage and to facilitate handling the freight carried. These will represent the ideas of some of the most expert designers of the country, and will be worthy the careful study of every man who has to do with haulage. There will be numerous standard bodies, some of which have been created with the purpose of utilizing differing types of chassis.

Merle L. Downs, Secretary, A. B. of T. Show Committee.

Besides the vehicles themselves there will be all manner of constructional detail that will be closely exam- examined by those who are desirous of information.

UNIVERSAL SAVES SAILORS' LIVES.

Responds to Hurry Call for Lifeboats During Storm Off the Massachusetts Coast.

During a recent storm off the Massachusetts coast a schooner was in distress with no boats to go to the rescue, but a motor truck travelled 35 miles to bring aid to the imperilled sailors. The New Bedford Motor Haulage Company, dealer in Universal trucks, made by the Universal Motor Truck Company, Detroit, had a vehicle in Newport, R. I., and this was put into service. The authorities at New Bedford telephoned for lifeboats but without an idea that anything could be done.

The Universal was rushed to the dock, where two lifeboats, each 27 feet, 6.5 inches long, were loaded, one right side up and the other upside down on top of it. The boats protruded at the rear and in front to bring an even balance, and weighed 3700 pounds. The governor on the motor was disconnected and the unusual load was taken successfully and speedily to the shore in 2:10:00, reaching its destination in time to save every man of the ship's crew.

WHITES IN PASSENGER SERVICE.

Indianapolis Concern Utilizes Seven, Each of Which Has Been Driven 60,000 Miles.

The Rapidtransit Motor Company, Indianapolis, Ind., which maintains a passenger service in that city, has in service seven White chassis which has each been driven 60,000 miles in a year. The machines are used 17 hours each day and the average mileage is 150, this being the same summer and winter.

When the year had been completed the machines were overhauled and were found to be in admirable condition, there being no evidences of deterioration or abnormal wear. This was regarded as being remarkable in view of the hard service each had endured, for without regard to weather conditions the schedules were maintained. Eliminating overhead expense the cost of operation was only 4.5 cents a mile, this figure being slightly exceeded in winter. The average was 10 miles to the gallon of gasoline and 300 miles to the gallon of lubricatng oil.

ELECTRIC SERVICE WAGONS.

Development of Industry as Reflected by Number in Use in New England.

In a recent article by Day Baker, president of the Electric Motor Car Club of Boston and treasurer of the Electric Vehicle Association of America, he showed the development of the use of the electric service wagon in New Engand, which he outlined numerically as follows: 1902, two; 1903, seven; 1904, nine; 1905, 10; 1906, 17; 1907, 21; 1908, 34; 1909, 62; 1910, 119; 1911, 193; 1912, 273.

Mr. Baker emphasizes that in the 11 years covered by the figures he gives that there has been a constant development, the manufacturers profiting by perience and perfecting the machines to a st they are not only dependable and reliable, but may be considered as insuring service for a long period of years. Mr. Baker pointed out that no matter what the form of motor vehicle used its value was entirely dependent upon the system by which it was worked and the facilities for handling the freight.

CUTS HAULAGE COST ONE-HALF.

Gramm Shows Splendid Economy Over Horses in Mountainous District of California.

A large Gramm truck, made by the Gramm Motor Truck Company, Lima, O., recently sold to a transportation concern at Lake Tahoe, Cal., is doing remarkable service for its owners, according to word received by A. T. Neely, manager of the Colyear Motor Sales Company, Los Angeles, Cal., distributor for this make. The vehicle covers 50 miles a day between the railroad and Lake Tahoe and to the various resorts and camps around the lake.

All the grades in the section are extremely heavy, some of them running as high as 22 per cent., but the Gramm goes over them without difficulty. During the past few months it has been hauling fruit and general merchandise. According to a carefully prepared analysis the machine has cut the cost of transportation about one-half that which would have resulted with a horse team. During the winter the truck is being used to haul material for road making and general construction.

CANADA OFFERS GOOD MARKET.

With Rapid Increase in All Lines of Business Will Come Demand for Efficient Haulage.

E. J. Kilborn, assistant sales manager of General Motors Truck Company, Detroit, maker of G. M. C. gasoline and electric trucks, has just returned from a trip that included Montreal and other Canadian cities. He is firm in his belief that Canada will present a good future market for American made motor trucks. He states that new buildings are springing up on all sides and statistics show that every year there is an influx of settlers into Canada from the United States.

When the demands of this immense new population for household goods, implements, tools, clothing, drugs and other necessities, as well as articles of commerce that are sought in all prosperous communities, are considered, the trade increase across the border can be understood. Coincident with heavy trade and shipping, a need arises greater than ever for efficient haulage and delivery methods. There is no question that every year will see a remarkable increase of motor vehicles in Montreal, Toronto, Winnipeg and other Dominion cities that are rapidly forging ahead.

NEW SERVICE VEHICLES AND THEIR FEATURES.

Constructional Details of Machines of All Classes, the General Purpose of the Designers Being to Simplify and to Secure Protection for Moving Parts with Provisions for the Fullest Accessibility.

THE Blair Manufacturing Company, Newark, O., is building three types of service wagons that have rated capacity of 3000, 5000 and 7000 pounds, and are, aside from the motors, identical in design, although they differ in proportions. The smallest model has a water-cooled motor with bore of 4.125 and stroke of

Blair 2.5-Ton Wagon, Model D.

5.25 inches, rated at 30 horsepower, with cylinders cast en bloc, and the motors for the larger vehicles are 4.5 inches bore and 5.5 inches stroke with a rating of 40 horsepower, with the cylinders cast in pairs. These engines are lubricated by a self-contained combination of splash and force feed system which is said to be extremely efficient, and the water is circulated by a centrifugal pump. The carburetor is a Schebler model O and the ignition is a Bosch dual system with fixed spark. The clutch is a leather faced cone with cork inserts. The transmission gearset is a selective type giving three forward speeds and reverse.

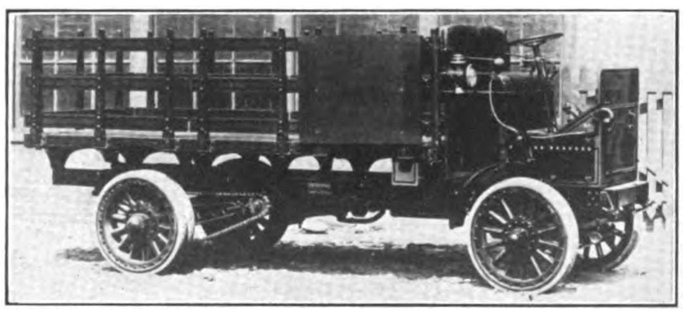
The motor is installed with the seats for the crew of the machine at either side and the hood over it may be raised by the driver without leaving his seat. This design economizes space, permits the advantages of the hooded motor and gives practically the body space that is to be found with the engine under the footboards. The drive is by a shaft and worm gear. The unusual feature of the construction is in the mounting of the motor and gearset, which is carried in a sub-frame supported by heavy cast steel brackets and hardened and ground steel pins at the forward end of the chassis frame. The rear end of the sub-frame is "necked" or cambered, and the two sturdy cross members are fitted on the steel housing of the worm drive gear, at the front and rear of the rear axle, on which housing the members may turn slightly.

As the rear axle may rise or fall from compression or recoil of the springs the sub-frame will move on the pins in the brackets on the forward end of the frame, and without stress of any kind upon the motor and driving system. As the rear axle is lifted or lowered at either side there is a slight movement of the cross members supporting the sub-frame at the rear on the worm gear housing, compensating for any change of relation and eliminating any strain upon the power plant or the driving mechanism. In other words, the sub-frame conforms to every influence that would tend to cause distortion of the chassis frame and result in deterioration. The driving force is exerted on the frame through the sub-frame. The radiator is mounted on springs and is not susceptible to the strains upon the chassis frame.

A feature of the transmission gearset is that the gears are always in mesh except when in high speed, when all the gears are idle. By a system of jaw and sliding clutch gear engagement is always easy and there is no possibility of stripping the gears. This is regarded as a highly essential quality in a service vehicle. The brakes are of liberal proportions and are all of the contracting type, the emergency on the rear wheels and the service brake on the propeller shaft. The machines are governed to what is regarded as a safe maximum speed. The steering gear is of the worm and nut type and is adjustable for wear. The front axle is a drop forged I section and the springs are semi-elliptic. The wheelbase of the 3000-pound wagon chassis is 114 and 121 inches, of the 5000-pound wagon 121 and 144 inches, and the 7000-pound truck 130 and 144 inches.

Three Universal Models.

The Universal Motor Truck Company, Detroit, Mich., is now producing three models of service wagons, of 2000, 4000 and 6000 pounds capacity. Of these the 2000-pound machine is guaranteed by the maker for 50 per cent. overload, which makes it in effect, at least, a 3000-pound vehicle. The smaller model has an L head motor cast en bloc with bore of 3.75 inches and stroke of five inches, rated at 30 horsepower. The water is cooled by a radiator of the vertical tube type with removable heads carried at the forward end of the chassis frame, and the lubricant is by the constant level splash system supplied by a gear driven pump. The ignition is by a dual high-tension installation. The



Universal Two-Ton Wagon.

clutch is a single disc dry plate type. The transmission gearset is suspended at three points and has three forward speeds and reverse. The drive is by shaft to

a worm gear contained within a full floating rear axle. The front axle is a heavy I section steel drop forging. The chassis frame is a steel channel section six inches width and .1875 inch thickness, with five cross members. This is mounted on semi-elliptic springs. The brakes are of the internal expanding type acting in drums 16 inches diameter with faces two inches width, all fully enclosed. The drive is from the left side by an irreversible gear with a wheel 18 inches diameter. The forward tires are 34 by 3.5 inches and the rear 34 by five inches. The wheelbase is 124 inches and the loading space is 108 inches by 60 or 144 inches by 60.

The two and three-ton chassis are fitted with the same motor, which is a T head type with the cylinders cast in pairs, rated at 36 horsepower by brake test at 900 revolutions a minute, having bore of four inches and stroke of 5.5 inches. The diameter of the crankshaft at the forward and middle main bearings is 1.75 inches and at the rear main bearing two inches. The main bearings are respectively four, 3.25 and 4.5 inches length. The crankcase is in two sections, the upper half carrying the main and camshaft bearings, and the lower half being the reservoir for the oil.

Wichita Two-Ton Wagon, Model B.

The motor is cooled by water driven by a centrifugal pump through a cellular radiator located under the driver's seat and by a fan incorporated with the flywheel. The lubrication is a self-contained constant level system that is circulated by a plunger pump through a sight feed on the dash. The ignition is a dual high-tension system. The clutch is a multiple disc construction that is operated dry. The transmission gearset is combined with the differential and gives three forward speeds and reverse. The drive is by side chains from the jackshaft sprockets to sprockets on the rear wheels. The chassis frame is a steel channel section six inches width with heavy cross members, and is carried on semi-elliptic springs. The external contracting service brake is located on the jackshaft, and the internal expanding emergency brake shoes are installed within drums on the rear wheels. The forward axle is an I section and the rear axle a rectangular drop forging. The wheels are 36 inches diameter and the wheelbase regularly furnished is 132 inches. The drive is from the right side by a worm and nut type steering gear and 18-inch hand wheel.

The specifications for the three-ton machine differ principally from the two-ton in the length of wheelbase, which is either 132 or 150 inches, in the weight of the material in the chassis frame, in the size of the tires and the maximum speed, which is 12 miles an hour instead of 15. The two and three-ton types are fitted with a power windlass driven by a chain from the jackshaft, which is controlled by the levers that control the machines. This is supplied as extra equipment.

Wichita Delivery Wagons.

The Wichita Falls Motor Company, Wichita Falls, Tex., is producing two types of wagon adapted for general purposes, of one and two tons capacity, which are when desired specially equipped with tanks for oil or water distribution or with apparatus for fire department service. The smaller of the two is model A and the larger is model B. The two machines are identical in design and the principal difference is in the motor, which is 3.25 inches bore and five inches stroke for model A and 3.5 inches bore and five inches stroke for model B. The wheelbase of model A is 110 inches and of model B 118 inches. The tire sizes differ, of course.

The motor is a water-cooled type with the cylinders cast en bloc and it has a crankcase of the barrel design with an aluminum oil reservoir bolted to the bottom. The timing gears are enclosed by an aluminum housing. The motor is supported by arms at either end of the crankcase. The crankshaft is unusually large with long main bearings of special nickel babbitt. The cylinders and pistons are carefully finished to insure high compression and the valves are large and have good clearance, with cast iron heads and nickel steel stems. The valves are all at the left side of the motor and are operated by a single camshaft that drives the oil pump. The camshafts are with the cams integral. The cooling is by thermo-syphon circulation and a radiator carried at the forward end of the chassis, the fan being driven by a flat belt from a pulley on an extension of the crankshaft. The lubrication is by a combination of splash and a force feed system, the oil circulating through a sight feed on the dash. The valve cover plates may be detached and the engine cleaned of carbon without dismantling the motor. The ignition is by either Bosch or Eisemann high-tension magneto.

The clutch is a leather faced cone and the transmission gearset is a selective sliding type with three forward speeds and reverse, the shafts being mounted in high duty roller bearings. The drive is through a jackshaft and side chains to the rear wheels. The forward axle is an I section drop forging and the rear axle is a rectangular steel forging. The frame is a pressed steel channel section and it is carried on semi-elliptical springs of liberal proportions. The wheels are artillery type, 34 inches diameter. The brakes are internal expanding, the service brake on the jackshaft and the emergency brake in drums on the rear wheels. The control is by a worm and sector gear at the right side with centre speed change and brake levers. The gasoline capacity is 24 gallons.

New Adams Truck.

Adams Bros. Company, Findlay, O., which is now producing 2000 and 3000-pound wagons, is manufac-

Adams One-Ton Wagon, Model A.

turing a 4000-pound machine which will be placed in the market within a very short time. The 2000 and 3000-pound machines are known as models A and D and differ principally in the size of the springs and the tires. The wheelbase of either may be 121 or 136 inches as desired. The new model will have 140 inches wheelbase and will have heavier springs and tires.

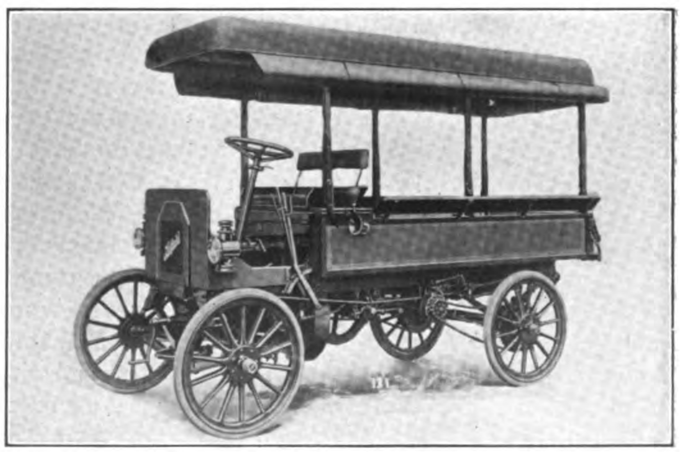
The motor is a vertical, four-cylinder, water-cooled unit with the intake at the right and the exhaust at the left, and is cast en bloc. The bore is 3.875 inches and the stroke five inches. The cylinders are so cast that there is complete circulation about the combustion and expansion chambers. The cylinders are very carefully fitted and ground and the pistons are finished with extreme care. The crankshaft is a drop forging of 3.5 per cent. nickel steel of large diameter and with unusually long main bearings. The bearings are of a special anti-friction metal of decided endurance. The camshaft is a drop forging of special steel with the cams integral, mounted on large bearings. It is actuated by spiral gears. The upper section of the crankcase carries all moving parts and the main bearings, and the lower half serves as a reservoir for oil. On a bracket at the forward end of the motor is mounted the magneto and the water pump, which are driven by a cross shaft, to which they are flexibly coupled. The lubrication is by a combination of splash and force feed and is said to be very efficient. The ignition is a dual high-tension system and the motor is cooled by water circulated by a spiral gear driven centrifugal pump through a vertical tube radiator installed back of the motor in the usual place of the dash, and a fan in the flywheel. The radiator is carried on flexible supports and is provided with two filler caps. The motor is covered with a hood that is hinged on the dash and when it is raised all parts of the engine are especially accessible.

The clutch is a multiple dry disc type and the drive is by shaft to a transmission gearset of selective design having three forward speeds and reverse that is assembled with the jackshaft. The gearset case is supported by two arms from a heavy cross member. The jackshaft shafts are not enclosed and each carries a brake drum inside the frame, on which the service brake contracts. The drive to the rear wheel sprockets is by chains. The front axle is an I section and the rear axle a rectangle, both drop forged. The frame is a wide pressed steel channel section that is "necked" between the forward wheels. The suspension is by generous semi-elliptic springs. The machine is driven from the left side by an irreversible gear of the screw and nut type with the control levers in the centre of the machine. The 2000-pound wagon is fitted with 36 by 3.5-inch tires forward and 36 by four-inch at the rear, and the 3000-pound wagon has the same size forward and the three-inch dual tires at the rear. The 4000-pound wagon will have 36 by four-inch tires forward and 36 by 3.5-inch dual at the rear.

Two Hatfield Models.

The Hatfield delivery wagons, built by the Hatfield Auto Truck Company, Elmira, N. Y., are intended to minimize cost of operation and maintenance and are somewhat unusual in design. The machines are of 1000 and 2000 pounds capacity and differ principally in spring and tire sizes and wheelbase, the former having 88 inches and the latter 96 inches. In these vehicles the front axle is of the same design that is used with an animal wagon and swings on a king bolt on a turntable. The motor is a three-cylinder, two-cycle, air-cooled type and the drive is by a driven wheel on a cross shaft that contacts with a plate attached to rear face of the flywheel of the motor. The power is transmitted from a sprocket on this cross shaft to a jackshaft, and from this by side chains to the rear wheels. There is no differential in the jackshaft; that is, a bevel gear and pinion device, but an expanding cam is enclosed in the brake drums on the ends of the jackshaft, and these are claimed to operate perfectly in making turns, and at the same time eliminating the possibility of a wheel spinning through loss of traction.

The motor is with 4.125-inch bore and four-inch stroke and is rated at 18-20 horsepower, but it is maintained it will develop 24 horsepower. Of the 99 parts of the motor but nine are moving. The cylinders are cast with wide and thin longitudinal fins and the heads are spherical. The crankshaft is a heat treated drop forging with extremely long main bearings. There are counterweights attached to insure exact balance. The



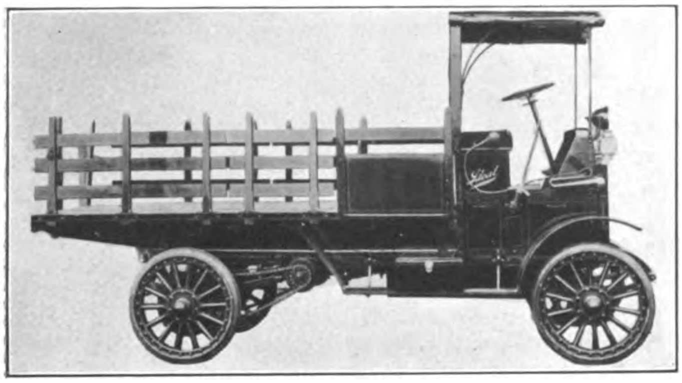
Hatfield One-Ton Wagon, Model K.

end of the crankshaft carries the magneto drive gear. The pistons are fitted with four rings, one below the wristpin. All parts are finished very accurately and

extreme care is taken to secure good compression. The ignition is by Bosch magneto and the lubrication is by oil supplied with the fuel.

Ahead of the flywheel is a heavy thrust bearing and this takes the thrust and prevents wear of the main bearings. The rim of the flywheel carries a series of blades that serve as a fan. The rear face of the flywheel is fitted with a plate of metal having a high coefficient of friction. This serves as the driving wheel and the periphery of the driven wheel on the cross shaft is faced with a fibre rim. The cross shaft is moved forward into contact with the flywheel face and transmits the engine power. Any ratio of speed can be obtained by the position of the driven wheel with relation to the flywheel.

The cylinders of the engine are covered with a light metal shield or jacket that has an opening close to a screen in the hood. There is a deck about the cylinders above the bottom of the radiating fins. The suction of the flywheel draws a current of air over the motor and down between the fins, effectively radiating the heat. The frame is of angle steel and the springs are ample. The service brake is on the jackshaft and the emergency brake is on the rear wheels. The



Ideal Two-Ton Wagon, Model G.

wheels are fitted with solid tires, 34 by three inches forward and 34 by 3.5 inches rear.

Ideal in Three Sizes.

The Ideal Auto Company, Fort Wayne, Ind., is producing three wagons, model G of 4000 pounds capacity, model H of 2000 pounds capacity and model I of 1500 pounds capacity, and of these model H has been redesigned. While its designation has not been changed a number of alterations have been made. The wheelbase has been increased from 115 to 120 inches and the engine is larger, having a bore of 3.75 inches and stroke of 5.25 inches, as against the old dimensions of 3.5-inch bore and 4.5-inch stroke, affording greater power. The frame of the former model was wood and steel, but this has been replaced by a pressed steel construction. Model G has been increased in capacity from 3000 to 4000 pounds by the use of heavier axles and springs.

Crawford Delivery Wagon.

The Crawford Automobile Company, Hagerstown, Md., is building a light delivery wagon of 1200 pounds capacity, which is intended for quick work. It is regularly delivered with an enclosed body, and is known as the model 13-30. It is equipped with either the model R Continental or the Crawford "35" motor, either having a bore of 4.25 inches and stroke of 4.5 inches, and being rated at 30 horsepower. The motor is water-cooled and is lubricated by a continuous supply of fuel from a gear driven pump. The ignition is a dual high-tension system. The clutch is leather faced with springs to insure easy engagement. There is a universal joint between the clutch and the gear set case that is enclosed in a water and dust tight case. The gearset case is supported by the sub-frame. The gearset gives three forward speeds and reverse and the shafts and gears are of nickel steel, mounted on Timken and Standard roller bearings. The torque tube at the forward end is carried by a globe and socket on the gearset case. The differential gear is constructed with four pinions, and is carried on Timken bearings. The torque tube is bolted to the full floating rear axle housing and the relation of the rear axle is preserved by radius rods. The front axle is a tubular type. The frame is a large channel section of pressed steel and it is carried on semi-elliptic springs forward and at the rear by half-scroll elliptic springs. The brakes are internal expanding and external contracting on drums 14 inches diameter and 2.5 inches face. The drive is at the right side and the control levers are at the driver's right. The tires are pneumatic, 32 by 3.5 inches forward and 32 by four inches rear.

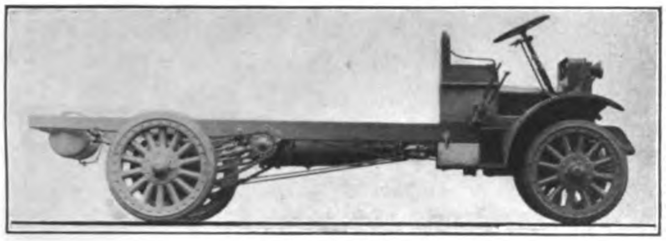
B. A. Gramm's New Designs.

The Gramm-Bernstein Company, Lima, O., with which organization B. A. Gramm is now identified, has begun the production of a two-ton wagon and a 3.5-ton truck, which are practically of the same design, and which differ principally in the size of the components, although both have the same motor equipment. There are some features of these machines that are maintained to be exclusive. One of these is the mounting of the Continental motor on a sub-frame carried by four coiled springs, another is transmission gearset having four speed ratios (for the 3.5-ton truck only), and a third is the Gray & Davis electric lighting and starting system, the storage battery of which furnishes current for ignition for an Atwater Kent unisparker. It is maintained that the engine starter will eliminate any need for the driver leaving the engine running unless it is actually needed for propulsion and will greatly economize in fuel and lubricant.

The motors are with cylinders cast in pairs, 4.5-inch bore and 5.5-inch stroke, and these and the clutches are carried on the sub-frames, which are supported by springs from the cross members of the chassis frames. The electric generator is mounted on the sub-frame and is driven by a silent chain from the pump shaft. The motor is located on the engine base and with a shaft and an over-running clutch actuates the motor through a rack on the engine flywheel. The motor is governed to a maximum speed of 1000 revolutions a minute.

The clutch is a multiple disc type with the clutch shaft discs faced on both sides with Raybestos. It is

enclosed in a dust proof housing. The inner end of the clutch is carried on a large radial ball bearing. An oilless graphite bearing is used between the housing



B. A. Gramm's 3.5-Ton Truck Chassis.

and the clutchshaft. The ball bearing needs lubrication with vaseline at long intervals. With the selective type transmission the gears are always in mesh, save when driving on the high speed. The gears of the main shaft are carried on roller bearings and the dog clutches are secured by six splines instead of the usual keys. The gears are of chrome nickel steel, the shafts of nickel steel, and both shafts are carried on annular ball bearings. The differential and gearset are in one assembly within a semi-steel case. The jackshaft is a full floating type with annular ball bearings throughout.

Timken axles, fitted with Timken bearings, are used. The frames are of pressed steel channel section of unusual width and depth and they are carried on semi-elliptic electro silica manganese springs, with improved steel shackles. The external contracting service brake operates on drums on the jackshaft within the chassis frame, and the internal expanding emergency brake shoes are within drums of large size on the rear wheels. The drive is at the right side. The dash, directly behind the radiator, carries the gauges and the indicators. Starting is accomplished by throwing the gear shifting lever into an additional position in the quadrant. The vehicles are lighted by electricity from the storage battery. Because of the design the beds of the vehicles are from six to 12 inches lower than the average, which is a quality of much importance when the load is to be handled by the driver alone. The wheelbase of the two-ton wagon is 128 inches and of the 3.5-ton truck 140 inches.

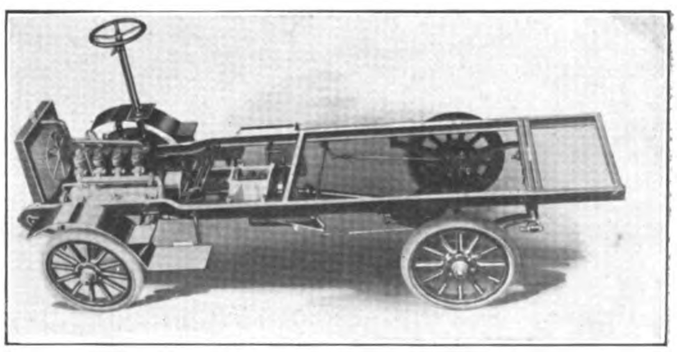
Toledo Succeeds Rassell.

The Toledo Motor Truck Company, Toledo, O., which succeeded the Rassell Motor Truck Company, is building two sizes of motor delivery wagons, one and two tons capacity. Both are much the same in general design and the components are produced by manufacturers of standards, these being the Contintal motors, Brown-Lipe gearsets, Timken front and rear axles, McCord radiators, Ross steering gears, Kinsey frames and Timken bearings. The motors and transmissions are mounted in sub-frames, which are suspended on three points and are freed from the distortion stresses that might be caused by the chassis frame without such protection. The assembly is such that the power plant can be removed from the chassis by disconnecting the water and exhaust manifolds, the fuel supply line and the throttle and spark linkage. The radiator is mounted in a cradle that is suspended on springs and it is not subjected to the strains of a fixed installation. The design is such that the motor is carried low, under the footboards and seat, yet it is extremely accessible. The carburetor, magneto, spark plugs, etc., can be reached through doors at the side of the body, and the connecting rods and the valve tappets can be adjusted without removing a bolt. The power plant of the one-ton wagon is a unit, with the transmission gearset included, but with the larger type the gearset is separate from the motor and clutch. The claim is made that these machines have very large loading spaces for the capacities, and that the loads when properly placed are so equalized as to minimize tire cost and maintenance expense.

The Practical Piggins.

The Piggins Motor Truck Company, Racine, Wis., is building three models of the Practical Piggins wagons and trucks, all of which follow a general design and differ mainly in the proportions of the components. The power plants are Waukesha motors, that of the one-ton wagon having a bore of 4.25 inches and stroke of 4.75 inches, and the two and three-ton chassis are equipped with a motor having a bore of 4.75 inches and stroke of five inches. These engines are rated at 30 and 40 horsepower, respectively, and are designed for a maximum of 1000 revolutions a minute. Accessibility is a feature of the design and the motor can be easily removed from a chassis after the radiator has been taken off.

The clutch is a cone type and the transmission gearset is a selective type with sliding clutches, in which all gears are constantly in mesh, the gears being of liberal size and the shafts carried on ball bearings. Directly back of the transmission case, on the extension of the transmission shaft, is the service brake. Coupled to this shaft by a universal joint is the driving shaft, which is enclosed in a tubular housing, and this housing is incorporated with a case that encloses a differential gear and the supplementary or countershaft. This shaft assembly is fitted with a large arm at either end which will turn on a wide babbitted bearing, and the other ends of the arms are secured to the squared rear axle. As the tubular hous-



Practical Piggins Three-Ton Truck Chassis.

ing is raised or lowered at the forward end its relation is always preserved and there is no stress upon the driving shaft. The ends of the countershaft carry

spur pinions that mesh with spur gears mounted on sleeves to which the wheels are secured.

The axle spindles are fitted with roller bearings of large size. The gears are enclosed in housings and are lubricated with a heavy grease. It is claimed for this construction that as the gears are of vanadium steel, heat treated, they have very long life. The weight of the vehicle and its load is carried on the dead axle and the stresses through road conditions are eliminated. The front and rear axles are high grade carbon steel forgings and are fitted with nickel steel spindles. The emergency brake is the internal expanding type and operates within drums on the rear wheels. The frame is a large channel section with generous cross members, the parts being drilled and assembled with rivets headed while hot.

Bessemer Increases Its Line.

The Bessemer Motor Truck Company, Grove City, Penn., has increased the number of its models to three, the capacities being 1000, 2000 and 3000 pounds. The first wagon built was of 2000 pounds capacity. These machines are practically to the same design and two sizes of motor are used, that for the smallest wagon, known as model A, being a vertical, four-cylinder, wa-

Bessemer One-Ton Wagon, Model B.

ter-cooled type with bore of 3.5 inches and stroke of 4.5 inches, and a horsepower rating of 18. Models B and C have a motor with bore of 3.75 and stroke of 5.25, rated at 22 horsepower. The motor capacity is reached at 1000 revolutions. The water circulation is by a centrifugal pump and it is cooled by a radiator and a fan. The lubrication is by a gear driven pump and the ignition is by a Briggs magneto. A Rayfield carburetor is used.

The clutch is a cone with a leather face and the transmission gearset is a selective sliding gear type having three forward speeds and reverse. The drive is by shaft, jackshaft and side chains to the sprockets on the rear wheels. The frame is a pressed steel channel section of liberal proportions and it is carried on semi-elliptic springs. The axles are steel drop forgings, the front axle of model A being square and the front axles of models B and C being I sections, while the rear axles are rectangular in form. The brakes are internal expanding and operate within drums on the rear wheels. The wheelbases of the models are 102, 120 and 136 inches, respectively.

The design of these machines has been with a purpose of securing accessibility of all the components, minimizing the labor that is necessary in giving the needed care and attention, and liberal allowance has been made to provide for wear and to insure long endurance under all conditions of service.

The New King 3.5-Ton Truck.

The A. R. King Manufacturing Company, Kingston, N. Y., has begun the manufacture of a 3.5-ton truck known as the King, which in general features follows conventional practise. The wheelbase is short through the power plant being mounted under the driver's seat. Emphasis is made of the high quality of material and workmanship entering into the construction and of the provisions made to insure against wear and deterioration. The motor is a four-cylinder, four-cycle, water-cooled, L-head type with bore of 4.5 inches and stroke of 5.5 inches, having a rating of 32.4 horsepower by the S. A. E. standard. The cylinders are cast in pairs. The motor is cooled by water circulated by a centrifugal pump through a vertical tube radiator and a large belt driven fan. The lubrication is by a self-contained force feed system, the oil being circulated through a sight feed on the dash to the crankcase, where it is distributed to the moving parts by splash, and the overflow is drained to the reservoir and is filtered and again used.

The ignition is by Bosch dual system with a set spark. The clutch is a multiple disc construction with the 21 steel plates faced with Raybestos. The engine and clutch are mounted as a unit in a sub-frame that is supported at three points, and this assembly may be removed from the front of the chassis without removing the seats or footboards. The end of the clutch shaft is supported by a roller bearing in the sub-frame, which prevents strain upon the rear bearing of the engine. The transmission gearset is selective, with three forward speeds and reverse, and the wide faced gears are always in mesh, the engagement being by sliding jaw clutches, so that gear stripping is impossible. The differential is assembled as a unit with the gearset, and the suspension of the assembly is by three points. The final drive is by double side chains from the jackshaft sprockets to those mounted on the rear wheels, the rear sprockets being detachable.

The frame is a rolled steel channel six inches width, and generous depth, and this is carried on semi-elliptic springs of Krupp steel, 44.5 inches length forward and 54 inches length rear, fitted with inch bolts of nickel steel, hardened and ground. The front axle is an I section drop forging of steel, and the rear axle is a rectangular section 2.75 by three inches. The wheels are artillery type fitted with demountable rims carrying 36 by six-inch tires forward and 36 by eight-inch dual tires rear. The radius rods are steel castings, mounted concentric with the sprockets, giving a constant chain tension under all loads. These rods are adjustable at the head.

The external contracting service brake shoes act on 10-inch drums on the jackshaft, and the internal expanding emergency brake shoes operate within 18-inch drums on the rear wheels. Both sets of brakes are equalized. The steering gear is an irreversible

type with a 22-inch hand wheel. The throttle lever is mounted on the steering column. The motor is governed to a maximum speed of 12 miles. Timken roller

United States Three-Ton Truck, Model D.

bearings are used in the steering knuckles, hubs and jackshaft hangers, and imported annular ball bearings in the transmission. Abundant provision is made for lubricating all the moving parts and for adjustment to compensate for wear. The wheelbase is 120 inches and the tread is 62 inches forward and 64.5 inches rear. The body platform is 156 inches and 72 inches, maximum length and width.

Features of United States Trucks.

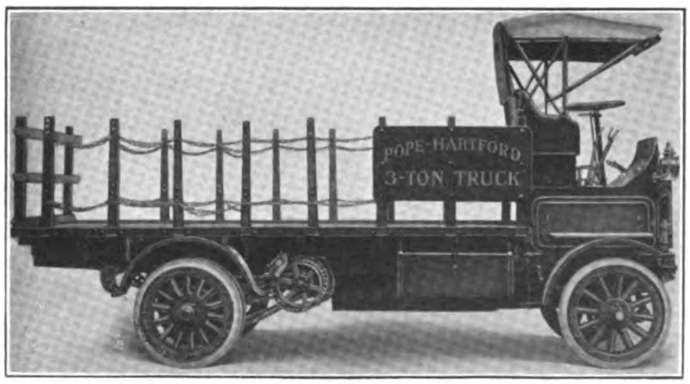
The United States Motor Truck Company, Cincinnati, O., is producing two models—type D of 6000 pounds capacity and type E of 4000 pounds—which are generally of the same design and differ practically in the proportion of parts. The machines conform to conventional practise, but for them special qualities are claimed in design of the transmsision gearset, in which the gears are always in mesh; in the suspension of the gearset case, this being a unit assembly with the jackshaft and mounted forward in a ball socket fitted to a cross member of the chassis frame, and with the ends of the jackshaft carried in globe sockets in the supporting brackets; in the straight line drive from the engine to the jackshaft; in the spring suspension of the motor; in the form of brake equalizer; in the metal seat frame and side panels; in the mounting of the radiator on springs; in the method of attaching the brake drums to the rear wheels with a clip around every spoke; in the demountable rims with which the wheels are fitted. The motors differ, that of the smaller vehicle being with cylinders cast en bloc with bore of 4.125 inches and stroke of 5.25 inches; that of the larger having cylinders cast in pairs with bore of 4.5 inches and stroke of 5.5 inches. The horsepower ratings are respectively 27.25 and 32.4. The rear axle of the 4000-pound machine is a round section and that of the 6000-pound chassis is rectangular. The wheelbase of model E is 132 inches and of model D 144 inches. Both machines have 36-inch wheels and the tires are respectively 3.5 and five inches for the forward wheels and 3.5 and five inches dual for the rear wheels.

New Five-Ton Pope-Hartford.

The Pope Manufacturing Company, Hartford, Conn., will build three and five-ton machines for the year to come. The smaller type has been considerably changed when compared with the 1912 vehicles, while the larger is new in every respect. The difference between the two, however, is practically a matter of chassis component proportions, for the same motor is used in both models. The results of experience and development have been combined in the two products and they are believed to be fitted to meet every requirement of service for which such vehicles could be utilized. As compared with the three-ton truck of 1912 the same type has been improved by an increased wheelbase, a transmission having four forward speeds and reverse, the use of locomotive type brakes on drums carried on the jackshaft, and other details of less prominence. The longer wheelbase permits the installation of bodies with larger carrying space, the fourth speed allows a greater range of effective power application, and the directly applied brake shoe is believed to be the more efficient.

The motor is the same in both models, being a four-cylinder, water-cooled, vertical type with the cylinders cast in pairs, and with bore of 4.75 inches and stroke of 5.25 inches. These are rated at 50 horsepower. The motor is cooled by a Pope-Hartford radiator of planetic type, the water being circulated by a centrifugal pump, gear driven, the system having a capacity of 8.25 gallons. The radiator is suspended in the chassis frame so that it is free from all torsional stresses. A belt driven fan cools both radiator and engine. The motor is lubricated by splash from reservoirs beneath the crankpins in which oil is maintained at a predetermined height by a suction pump. The excess oil is drained to the main reservoirs and after filtration is again circulated. The ignition is by a dual system, with an Eisemann high-tension magneto, with automatic spark advance. The motor is mounted on a subframe and is accessible through removable side panels of the housing.

The clutch is a cone, 17.75 inches diameter and 2.875 inches face, covered with a material having a high coefficient of friction. The transmission is a sliding gear type with four forward ratios and reverse, with direct drive on the fourth. The differential is a spur gear construction, with chrome nickel steel gears and large shafts, enclosed in the jackshaft housing. The drive to the rear wheels is by side chains. The

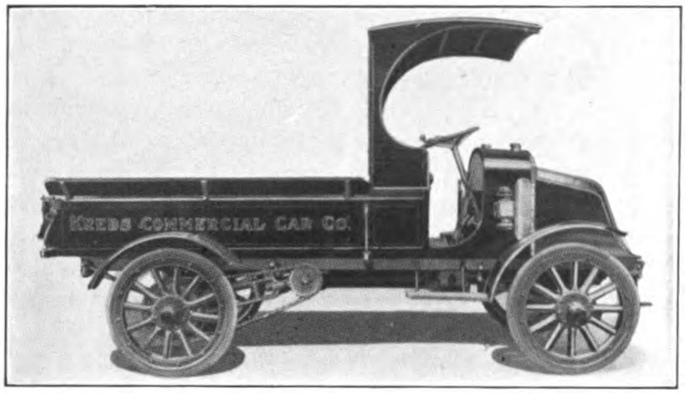


Pope-Hartford Three-Ton Truck.

springs are semi-elliptical with two heavy duty helical auxiliary springs located over the rear axle that come into use when the vehicle is heavily loaded. The for-

ward axle is an I section of unusually heavy construction and the rear axle is a rectangular section of large proportions. The service brake shoes contract on the drums on the jackshaft and the emergency brake shoes expand within drums on the rear wheels.

The control is by a steering wheel at the left side, 22 inches diameter; the throttle lever is under the wheel on the steering column, the left pedal operates the clutch and the right the service brake. The foot accelerator is convenient to the other pedals. The brake and gearset levers are at the driver's right. The three-ton model has 36-inch wheels fitted with demountable rims; the five-ton truck has 36-inch forward wheels and 42-inch rear wheels, with demountable rim equipment. The wheelbase is 138.5 inches for the three-ton machine, or a special chassis is built with 160 inches wheelbase. The tread of the three-ton truck is 67 inches forward and 68 inches rear. The five-ton truck has a wheelbase of 140 or 160 inches, and a tread of 67 inches forward and 74 inches rear. The speeds are 12 and 10 miles an hour for the small and the large truck, respectively. These machines are sold with



Krebs 1500-Pound Wagon, Model A.

standard type bodies and with either cab or buggy tops.

Krebs Delivery Wagons.

The Krebs delivery wagons, built by the Krebs Commercial Car Company, Clyde, O., are designated as models A and B, the former having a capacity of 2000 pounds and being driven by side chains, and the latter a capacity of 1500 pounds and being driven by a shaft. Model A is fitted with solid and model B with pneumatic tires. Model B is the faster of the two machines. In other details both are the same.

The motor is a two-cycle, water-cooled, two-cylinder unit with bore of 4.5 inches and stroke of five inches, that is rated at 16.2 horsepower and will, it is claimed, develop 24. The maximum of revolutions a minute is 900. The motor is exceedingly simple in construction and is mounted so that by the loosening of eight bolts it may be removed from the chassis frame. It is cooled by circulation of water by thermo-syphon through the water jackets and a radiator that is incorporated with the dash, and by a fan driven by a belt from a pulley on the crankshaft extension. The lubricating oil is fed with the fuel and the ignition is by Bosch high-tension magneto. The motor is covered with a hood of the conventional Renault type.

A cone clutch, of which the flywheel is a member, is used, and the power is transmitted through a selective sliding gearset with three forward speeds and reverse, and thence by a propeller shaft direct to the rear axle of the full floating design, or to a jackshaft. The model A rear axle is a rectangular drop forging. The model B rear axle is fitted with New Departure ball bearings and the shaft is designed with two universal joints. The frame is of pressed steel channel section four inches width and two inches depth, of .1875 inch thickness. The springs are semi-elliptical and the wheels are fitted with 34 by three-inch solid or 34 by four-inch pneumatic tires. The wheelbase is 100 inches with either model. The drive is from the left side with centre control levers.

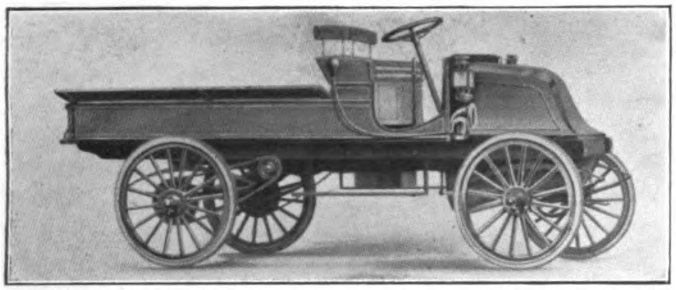
Brockway Wagons.

The Brockway Motor Truck Company, Cortland, N. Y., has announced the production of three types of wagon chassis adapted for differing business purposes. These have been perfected with a view of meeting the requirements of those who desire economical and dependable vehicles, and the development has extended over a period of about five years. The model A chassis is rated at 20 horsepower and its motor is a two-cycle, three-port, air-cooled, vertical type, with three cylinders of four-inch bore and five-inch stroke. The motors have but seven moving parts, the pistons, connecting rods and the crankshaft, and are extremely simple in construction. The cylinders are cast separately of a special quality of fine gray iron and are rough bored, annealed and ground to size. The pistons, of the same material, are specially treated to maintain the quality and to insure an accurate fit. The wristpins are large and are fitted to the pistons with Woodruff keys and cottered.

The crankshaft is large diameter and of a special alloy steel. All the engine bearings are bronze and well fitted. The engine case is provided with liberal hand-holes for the adjustment of the connecting rod bearings. The fan bladed flywheel is keyed to the crankshaft. The engine is cooled by a circulation of air drawn through openings in the Renault type of hood, a draft being insured by the shield that protects the lower section of the engine case. The carburetion is by a carburetor of the automatic float feed type and the lubrication is by oil mixed with the fuel, there being one part of lubricant to 20 parts of gasoline. The ignition is by a Bosch magneto with fixed spark. The power plant is mounted in the forward end of the chassis with a universal connection at the front and by arms at the rear.

The drive is through a cone clutch and a planetary reduction gearset giving two forward speeds and reverse, the entire assembly running in a bath of oil, a jackshaft and double side chains to sprockets on the rear wheels. The chassis frame is of wood reinforced with steel angles, and is maintained to be specially strong and efficient. The springs are full elliptic, front and rear. The axles are steel forgings, with large spindles. The wheels are artillery type, 36 inches

diameter front and 38 inches diameter rear. The brakes are internal expanding on the rear wheels. The control is with a throttle lever on the steering wheel,



Model A Brockway, 1000 Pounds Capacity.

low speed with the left pedal, reverse with the right, brake with the centre pedal and the hand lever for high speed. The steering gear is an irreversible worm and sector type. The wheelbase is 100 inches and the tread 58 inches.

The model B chassis differs from the model A in that the drive is through a gearset of a selective type giving three forward speeds and reverse, and the clutch is a leather faced cone. The sizes of the axles are increased and the wheelbase extended to 106 inches. The service brake is internal expanding on the jackshaft, and the emergency brake of the same type on the rear wheels. The control follows standard practise as regards pedals and levers. The model C chassis has a motor with cylinder bore of 4.5 inches and stroke of five inches, rated at 30 horsepower, and it has a wheelbase of 112 inches. In other respects it resembles the model B. Model A is rated at 1000-1500 pounds capacity; model B, 2000-2500 pounds capacity, and model C, 3000-3500 pounds capacity.

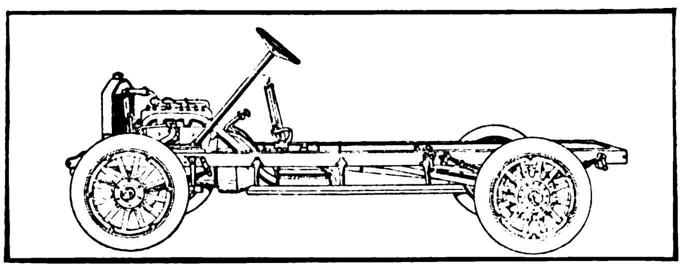
Brown Commercial Car.

The Brown commercial car, built by the Brown Commercial Car Company, Peru, Ind., is a new product and but one type, of 1500 pounds capacity, has been placed in the market. This is sold fitted with stake platform, covered express or fully enclosed body. The wheelbase is 122 inches and the tread 56 inches. It is a conventional design and the drive is by shaft from the transmission gearset to a jackshaft mounted back of the rear axle and by pinions on this shaft meshing with internal gears on the rear wheels.

The motor is a four-cycle, vertical, four-cylinder, L-head type with the cylinders cast en bloc, with bore of 3.75 inches and stroke of 5.25 inches, having a horsepower of 22.5 by the S. A. E. rating. The intake manifold is cast integral with the cylinders, heating the mixture before it is supplied to the combustion chambers. The crankcase is divided longitudinally and the lower half contains the oil reservoir, the upper half supporting the main bearings. The pistons are fitted with four rings. The crankshaft is a drop forging of .35 carbon steel, heat treated and ground, 1.75 inches diameter, mounted in three main bearings, respectively, 2.75, three and four inches length, of Parsons' white bronze. The connecting rods are the same material and have big end bearings 2.5 inches length and wristpin bearings one inch diameter, the bushings being of Parsons' white bronze.

The lubrication is by two plunger pumps driven by eccentrics on the camshafts by which the oil is pumped through tube to the timing gears and main bearings. The drainage maintains a constant level in the base of the engine case and splash lubricates the crank pins, wristpins, camshaft bearings, valve tappets, pistons and cylinders. The overflow drains to the reservoir, where it is filtered and used again. Draining the oil reservoir and cleaning the filter is provided for. The motor is cooled by a circulation of water by a centrifugal pump through the large water spaces of the motor, the vertical tube radiator supported on coiled springs, and by a fan driven by a belt from the forward extension of the crankshaft. The carburetor is an automatic float feed type with throttle on top of steering wheel, and ignition is by a Remy RD magneto.

The clutch is a multiple dry plate type with the plates faced with anti-friction material. The transmission gearset is a selective design with three forward speeds and reverse, with large shafts carried on imported annular ball bearings and with gears of 3.5 per cent. nickel steel. The engine, clutch and gearset are assembled as a unit. Both the emergency brake and the speed changing levers are mounted with the power plant and are free from stresses from chassis distortion. The driving shaft from the gearset to the rear axle is 1.75 inches diameter, with two universal joints, and is enclosed in a torque tube. The relation of the rear axle is maintained by two tubes extending from the brake spiders on the rear axle to a cross member of the chassis, the globe forward ends being mounted in bronze bushed sockets. There is ample provision for adjustment. There is the usual bevel gear differential in the jackshaft. The frame is pressed steel and mounted on semi-elliptic springs, 40 by two inches forward and 50 by two inches rear. The front axle is an I section, drop forged, with drop forged heat treated nickel steel spindles, fitted with annular ball bearings. The rear axle is drop forged steel and the spindles are equipped with annular ball bearings. Large annular ball bearings and large shafts are used in the jackshaft. The solid axle carries the load of the vehicle. The wheels are artillery type,



Brown Commercial Car, 1500 Pounds Capacity.

with large spokes, and are shod with 34 by 3.5-inch Motz tires forward and four-inch Motz tires rear, or with 34 by 4.5 pneumatic shoes on demountable rims.

Knickerbocker Five-Ton Model.

The Knickerbocker Motor Truck Company, New York City, is building a five-ton truck that is desig-

Knickerbocker Five-Ton Truck, Model 12-5.

nated as 12-5, and which is to the same design of the 3.5 and four-ton trucks that this concern has built during the last year. It has the quality of extreme accessibility with reference to radiator, motor, clutch, steering gear, gearset and jackshaft, and it is possible by swinging the radiator and loosening the connections to draw out the power plant, which is mounted on a hickory sub-frame. It is maintained that the hickory sub-frame absorbs the vibration from road shocks to which the motor would ordinarily be subjected, and that it also lessens the degree of engine vibration and its influence upon the other components of the chassis. The transmission gearset is designed to have the gears constantly in mesh and the sliding jaw clutches take the strain equally instead of the stress of starting being upon several teeth of a gear. It is a selective type with three forward speeds and reverse. The gears and shafts are chrome nickel steel and the bearings are the imported separated annular type. On direct drive all gears are idle. The jackshaft is a full floating form contained in a one-piece pressed steel housing, and it is fitted with Timken bearings.

The motor is of the L head type with the cylinders cast separately, with bore of 4.75 inches and stroke of five inches. It is cooled by a circulation of water that is forced through a large radiator by a centrifugal gear driven pump and a belt driven fan. The lubrication system is a combination force feed and splash. The pistons, of unusual length, are fitted with five rings. The crankshaft is 1.875 inches diameter and has five liberal main bearings. The wheelbase is optional with the purchaser.

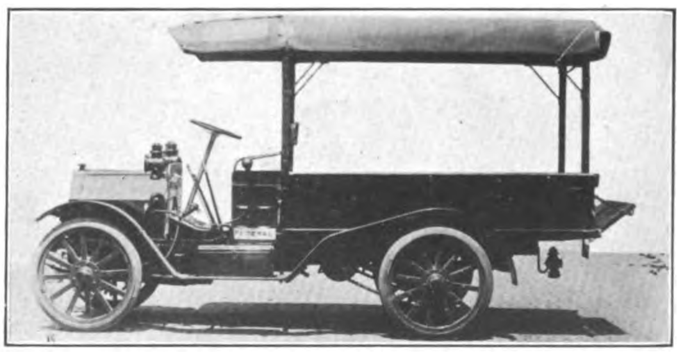
Federal of Standard Design.

The Federal Motor Truck Company, Detroit, Mich., has made no change whatever in the design of the machine it is producing, and it has been practically standardized, although they are specified as models C and D. The only difference is in the length of wheelbase, which is 110 inches in the former and 144 in the latter, and the longer chassis is approximately 100 pounds heavier than the shorter. The motor is a four-cylinder, water-cooled type with cylinder bore of 4.25 inches and stroke of 4.5 inches, the cylinders being cast in pairs. The valves are on the left side. The water circulation is by a gear driven centrifugal pump and the lubrication is by the constant level splash system. The crankshaft has three large bearings and is of unusual size. The ignition is by a high-tension magneto with fixed spark and the gas is controlled by an accelerator pedal.

The motor, clutch and the transmission gearset and the jackshaft are arranged as units and are unusually accessible. The gearset case and the jackshaft housing is a single assembly and these may be removed with comparatively little labor. The radius rods are a special design in which relation of the rear axle and jackshaft is always maintained and the stresses of driving are eliminated from the springs. The radius rods, brakes, steering gear and control members are adjustable from the outside with minimized labor. The axles, axle bearings, wheels, chains and sprockets are much heavier than is the standard practise with vehicles of the same capacity. The rear sprockets and the hub brake drums are a unit, and the drums are secured to the spokes of the wheels by North bolts, one through each spoke. The wheels are unusually heavy construction. The drive is left side with the speed and brake levers outside of the machine. The control by the pedals and the accelerator leaves the driver's both hands free to handle the wheel.

Standard Motor Trucks.

The Standard Motor Truck Company, Detroit, Mich., has placed in the market the Standard truck of three tons capacity, which, it is announced, is a combination of standard components and design, the result of the development by experts since the inception of the industry. The machine reflects all the standards of the S. A. E. as well as the experience and knowledge of the designer. The truck is conventional throughout, it including Continental motors, the gearset transmission of the Brown-Lipe Gear Company, Timken jackshaft and axles, Gemmer steering gear and Perfection springs. The purpose of the builder is to produce a vehicle that will be in every way accessible and enduring and afford a very large measure of practical service. The machine is built in a stand-



Federal One-Ton Wagon, Model C.

ard wheelbase of 144 inches and in special chassis of 120, 168 and 192 inches. With four lengths of chassis frame the buyer has the option of loading space from

102 inches with the shortest to a maximum of 255 inches with the longest, or 12 different possibilities—three with each chassis.

The motor is a four-cylinder, L head, water-cooled type with bore of 4.5 inches and stroke of 5.5 inches, rated at 40 horsepower. The power plant, clutch and gearset is a unit, and it may be taken out without hoisting by removing the radiator and forward cross frame member that serves as a bumper. The motor may be governed to a maximum speed of from 600 to 1000 revolutions a minute. The cylinders of the engine are cast in pairs. The motor is cooled by water circulation and a radiator and 18-inch fan. The lubrication is by a positive plunger pump system with one lead of tube to the timing gears and another to the rear main bearing. The ignition is by an Eisemann magneto with automatic spark advance.

The clutch is a multiple dry disc type, the plates being faced with Raybestos. The transmission gearset is selective, with three forward speeds and reverse, with all gears and shafts of 3.5 per cent. nickel steel, heat treated, the shafts operating on Timken roller bearings. The drive from gearset to the jackshaft is by a shaft fitted with two universal joints. The jackshaft is contained in a pressed steel housing with shafts and gears of nickel steel, mounted on Timken roller bearings. It is a single assembly and may be easily removed. The frame is a six-inch channel section of pressed steel .4375 inch thickness. It is carried on semi-elliptic springs, 45 by 2.5 inches forward and 52 by 3.5 inches rear. The radius rods are steel castings of wide section and are swivelled close to the jackshaft to prevent stresses from either vertical or transverse action of the axle or chassis. There is no strain upon the adjusting screws. The axles are the Timken standard and fitted with wheels shod with 36 by five-inch single tires forward and 36 by five-inch dual rear tires. The rims are demountable.

The service brake of the external contracting type acts on drums on the jackshaft, and the emergency brake, operated by a hand lever, expands shoes in the 18-inch pressed steel drums on the rear wheels. The speed changing and the emergency brake levers are located at the centre of the machine on the cover of the gearset case. The steering gear is a worm and sector operated by a 20-inch hand wheel. The moving parts are all fitted with large grease and oil cups and there are means for adjustment throughout.

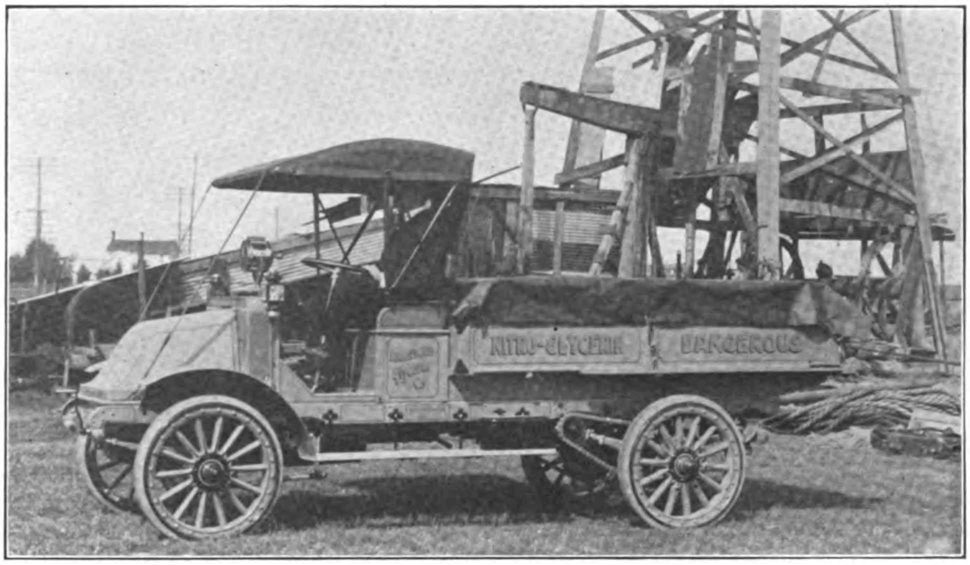
The new city administration of Haverhill, Mass., has recommended motorization of the fire department.

ADAMS HANDLES NITROGLYCERIN.

Special Bodies Fitted to Regulation Chassis with Satisfactory Results in This Field.

The American Glycerin Company is delivering nitroglycerin to the oil well regions in Adams trucks, made by the Adams Bros. Company, Findlay, O., and an accompanying illustration shows one of these vehicles about to deposit its load of 720 quarts of the explosive and the shells used for lowering it into the wells. The handling of this product is of interest to those who are unfamiliar with the characteristics of nitroglycerin.

The explosive is marketed in two forms, one being that in which it is mixed with some porous substance and formed into sticks, known as dynamite, and the other in the liquid state. In the latter instance it is carried in cans, not unlike those used for maple syrup. These usually are packed in sawdust to avoid the possibility of shock. Nitroglycerin may be burned in an open vessel without danger, but when heated in a closed can it will form a highly explosive gas. It usually is exploded by detonation.



Adams Truck Utilized by American Glycerin Company for Handling High Explosives.

Certain precautions must be taken in providing a suitable truck body, such as the use of special shock absorbing springs, pneumatic tires, etc., but the chassis utilized in this instance is the regular stock Adams product. Records of operation indicate that the Adams truck has an efficiency of two-thirds more work than with horses.

The Standard Glass Company, Chicago, recently purchased a Buick light delivery truck, made by the Buick Motor Company, Flint, Mich., which has since been used for the transportation of plate glass, and during the nine months of its service no injury has been caused to goods. W. L. Eaton of the firm was pessimistic about the success of the experiment, but he is well pleased with the results obtained.

ADVANTAGES OF THE RECORDING DEVICE.

Instruments Designed to Aid the Owner to Realize Maximum Efficiency from His Equipment —The Taximeter, and Its Counterpart on Mechanical Transports.

BEFORE the advent of the mechanical transport, the large majority of business men seemingly gave little thought or study to the question of transportation. Horses were employed for local haulage, and goods that were to be sent longer distances were shipped by freight or express. Slight attention was paid to the item of cost, it apparently being assumed there were no other methods available. Even the men engaged in supplying the necessary horse transportation were unable to state definitely whether they were doing business at a loss or a profit.

When the motor truck salesman appeared with his statements respecting cost a ton-mile, etc., he found in many instances that men who were familiar with every detail concerning the cost in other departments had no data at hand upon which to base a comparative estimate. All this has been changed, and it is now held to be possible to determine with every degree of accuracy whether a given installation, be it motor vehicles or horse wagons, is a paying proposition.

Two Views of International Taximeter, Indicating Separate Totalisers and Their Functions.

It may be assumed for the purposes of this discussion that a department store is investigating the possibilities of motor vehicles as applied to its delivery system and as compared with horses. It may be, and doubtless is true in many instances, that electrics possess certain advantages over gasoline cars in such work. It will be conceded that if this firm can be placed in a position to know absolutely what it will cost to operate each type of vehicle, or better still each vehicle, it then will be able to act upon such information, both in the purchase of equipment and in the arrangement of its delivery system to meet the requirements which will be disclosed.

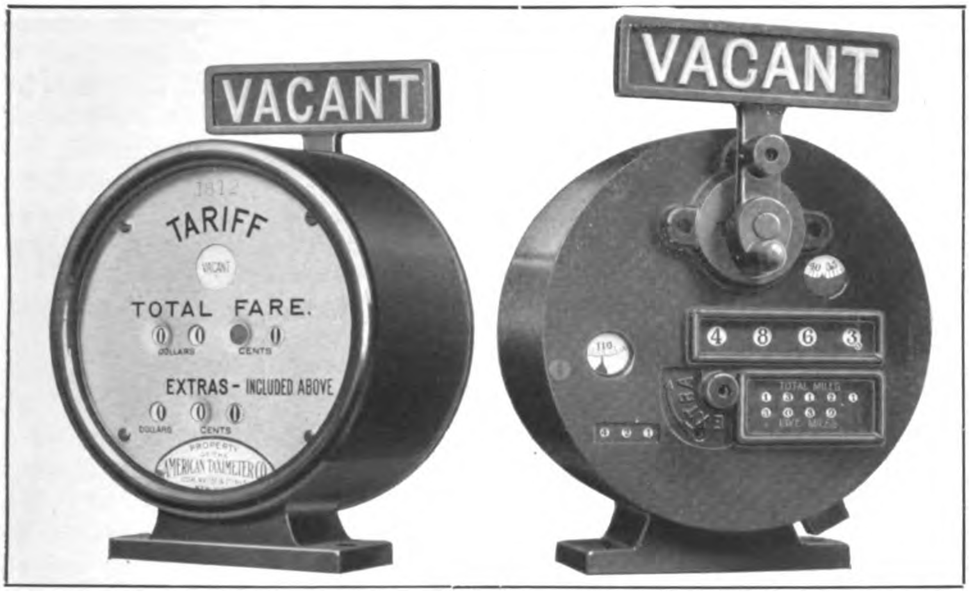
Many transfer companies have become convinced that the motor truck offers advantages, particularly in long haul work, which merit careful investigation. But if they have been engaged in transportation service for years with horses without being able to tell definitely whether or not they were making a profit on the individual job, feeling satisfied if the aggregate of the year's business showed a balance on the right side of the ledger, they hardly can have acquired the information they desired in this connection. As with the department store it becomes necessary to secure accurate data as to the cost of each piece of work, so far as that may be determined.

The list might be continued indefinitely. It is sufficient to state that concerns doing a large haulage business find this kind of information so valuable that they are willing to enlist the services of experts in securing the required data. And if it is of value to such companies, it must follow that those who have less capital involved, and consequently must be careful to obtain the maximum efficiency from their equipment, will find a study of this subject of direct personal interest.

The taxicab may be selected as presenting certain phases of the problem, the solution of which will indicate in a measure what is desired. The taxicab is returning money on the investment only when it is engaged. The reduction of the so-called dead mileage is of prime importance, but it is necessary to learn other details, and for this purpose taximeters are installed upon the vehicles.

These instruments are designed to record the fare, covering the mileage, waiting time and extras, or incidentals. In addition, they present to the owner a complete and accurate account of his vehicle while in service. Every effort is made by their manufacturers to produce a reliable recorder, which shall faithfully perform its function in these two particulars, at least.

Herewith are presented a number of taximeters on the American market, and with each the object sought is the same, although the method of their operation may differ slightly. Briefly, when the flag is exposed in an upright or prominent position, the vehicle is for hire. When this flag is lowered the initial charge is marked up on a certain dial, and thereafter the various items of the charge are added in sequence until the total fare is paid and the vehicle is dismissed.



Front and Rear Views of Jones Taximeter, Showing Owner's Check on Vehicle's Earnings.

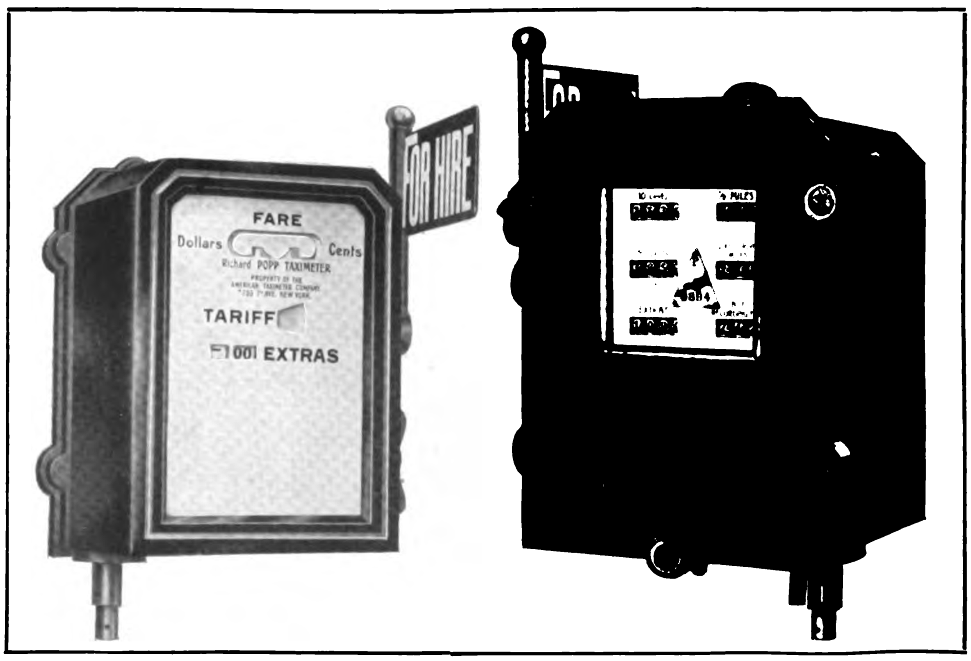
Two views of the International, made by the International Taxameter Company, 230 West 68th street, New York City, are shown. The first indicates that the cab is for hire. The second presents the condition of the record at the moment the vehicle is engaged. As the flag is lowered an initial charge of 40 cents for the first half-mile appears in the opening marked "Fare." A further reading of the instrument shows that there is a charge of 20 cents for "extra"; the initial totalizer at the bottom reads 0213 instead of 0212, one number greater than before the flag was dropped; the extra totalizer shows at 0266 instead of 0265, while the fractional totalizer registers the same, 8465, because no fraction of a mile or waiting time has been registered as yet. These totalizers remain in full view and cannot be set back.

In addition, the construction is such that there is a record by tenths of a mile for total mileage and another for dead mileage. A non-recording feature also is included, but this is limited and automatic. Once this mechanism is set in operation, the taximeter is placed beyond the control of the driver. When the limited period is completed the meter reverts to recording time or mileage, according to the conditions under which the machine is working. For instance, in case of accident, when necessary to make repairs: After 20 minutes the non-recorder automatically resets and the meter resumes its function. No matter what attempt might be made to prolong the non-recording period, it would be ineffective unless a new initial charge were recorded, in which event the initial amount registered would be chargeable to the driver of the vehicle.

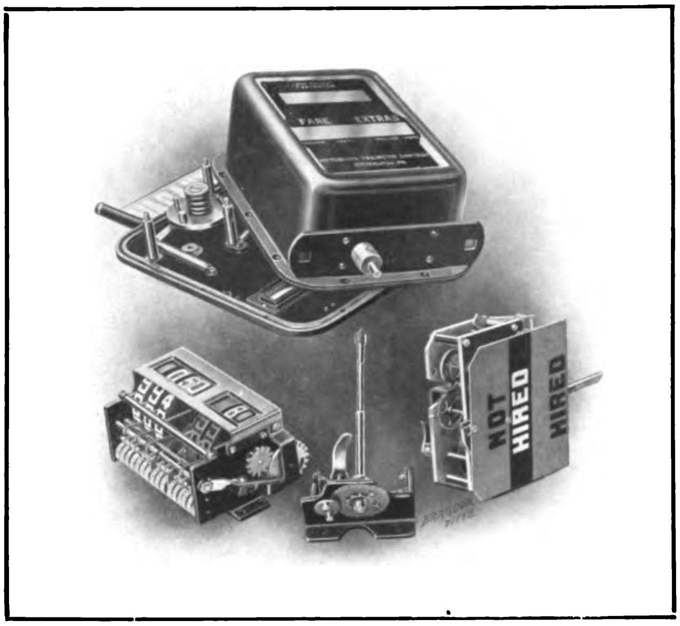
The Jones and Popp instruments, both made by the American Taximeter Company, 49th street and Seventh avenue, New York City, the former of American design and the latter of French origin, perform similar functions. They are fitted with "not registering" features, which permit of disconnecting further registration without disturbing the amount of fare then indicated. Accompanying illustrations set forth the front of the instruments and are readily understood. The rear views show the owner's record for each, giving an accurate account of the cab's movements, including total miles, dead mileage, number of trips, amount of cash collected, number of extras recorded and the time the meter was used in the "not registering" position.

Another illustration presents the Pittsburg taximeter, made by the Pittsburg Taximeter Company, Pittsburg, Penn., disassembled, the better to indicate the internal mechanism. It should be stated that the maker claims for this instrument that it has fewer parts than others, and that every part is interchangeable. A Yale lock protects the controlling device against the possibility of back reading.

It will be of interest to add that most taximeter companies rent but do not sell their instruments. The contract with the International Taxameter Company, for instance, covers one year, and makes provision for keeping the instruments in working order. The Pittsburg Taximeter Company sells its product outright,



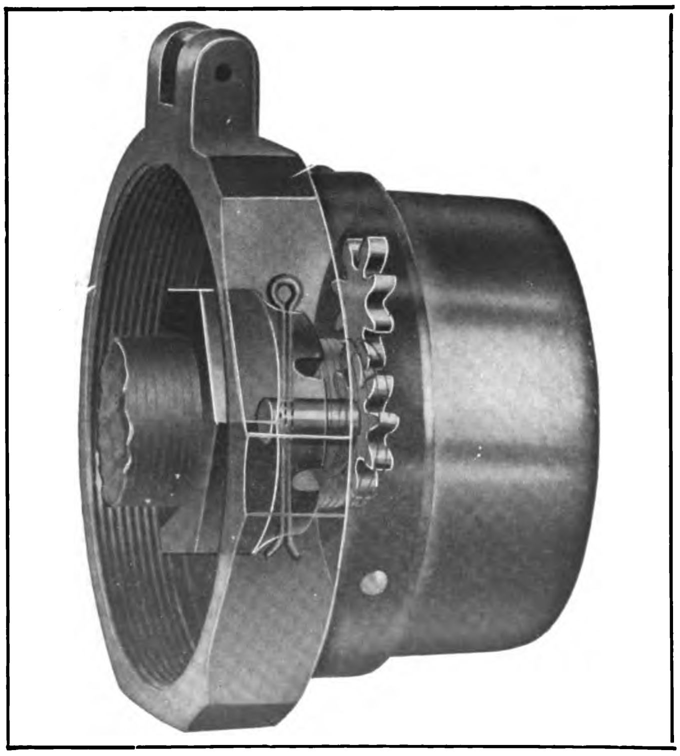
Front and Rear Views of Popp Taximeter, Presenting Information Available to Owner.



Pittsburg Taximeter Disassembled to Show Interior Components.

and it is guaranteed for one year. Inasmuch as the driving mechanism is reduced by gearing at the point where it enters the taximeter, the company claims that the instrument revolves very slowly and the wear is very slight, so that it should last indefinitely.

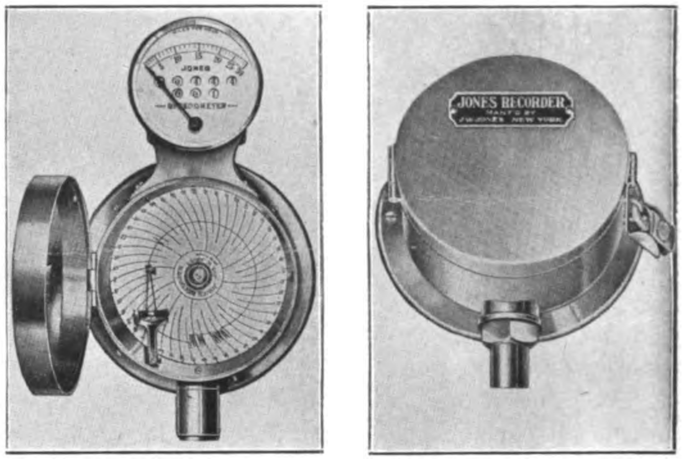
But taximeters were designed for use on taxicabs, and while they present features which are valuable in solving the peculiar problems of that business, their main purpose is different than those strictly required by the ordinary commercial vehicle. It may not be too much to suggest that the need for them and their method of accomplishing what is desired has resulted in incorporating some of their features in other recording devices which are now on the market.



Shadow View of Veeder Hub Odometer, Indicating Method of Operation.

And it may be added that even an instrument so complete as the taximeter has not entirely solved all of the problems of the taxicab owner, for a number of concerns are utilizing the Veeder hub odometer, for instance. The Fisk Rubber Company has installed it on several hundred cabs for which it supplies tires on a mileage basis, an indication of the value of this type of recorder.

The Veeder is made by the Veeder Manufacturng Company, Hartford, Conn., and comprises a small spur gear which meshes with a larger gear and suitable mechanism inside a cap which fits over the hub. No matter whether the car is driven forward or backward, the registering mechanism revolves in the same direction, and all of the distance travelled is recorded. The whole is securely sealed and the record cannot be changed in any manner without the owner's knowledge. This supplies accurate information as to the distance covered, and proves of value in checking up the totals indicated on the taximeter. It is equally as valuable for the truck owner in determining the mileage obtained from tires, etc.



Jones Recorder Opened and Closed, Presenting Type of Chart and Character of Record.

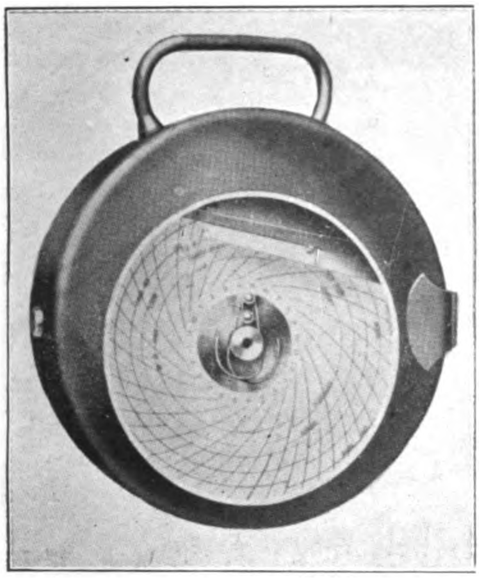
The Jones Speedometer Company, New York City, also manufactures a hub odometer along the same lines and for the same purposes. In addition it produces the Jones recorder, which may be used either with or without the speedometer attachment. The instrument is enclosed in a heavy brass case and may be attached to the dash or in any other convenient place on the car. It is connected by flexible shaft and gears to the front wheel, in exactly the same manner as the Jones speedometer. A marking stylus travels over a chart of sensitized paper, which cannot be tampered with, without unlocking the instrument, and which gives a permanent record of the vehicle's movement.

The Speedograph is now marketed by the American Taximeter Company. It is a combination device, including a speedometer, and when closed all parts are securely locked against anyone not in possession of the key. The lower portion contains the speedometer, which is connected by a train of gears with the actuating device at the top. The chart in this instance is in the form of a tape, on which a recording pencil

keeps accurate record of the vehicle's every movement.

Another form of tape record is made by Delivery Supervision Company, New York City, which recently took over the business of the International Delivery Supervision Company of that city. The tape is wound upon a drum, which is encased and connected with the road wheels of the vehicle by a flexible shaft. It is located on the dash, and the record is permanent in every respect.

The ServiS recorder, made by the Service Recorder Company, 2344 East 105th street, Cleveland, O., comprises a Seth Thomas eight-day clock movement and a brass disc, which is revolved once every 24 hours past a jewel pointed stylus, which registers travel and stop periods on a printed chart of sensitized paper, lying flat on the disc and travelling with it. The stylus, being attached to one end of a free swinging pendulum, marks a thin, clear line on the chart so long as the vehicle is quiet. But when the truck is in motion the pendulum is agitated to and fro, and the stylus marks a broad travel line about .25 inch wide.

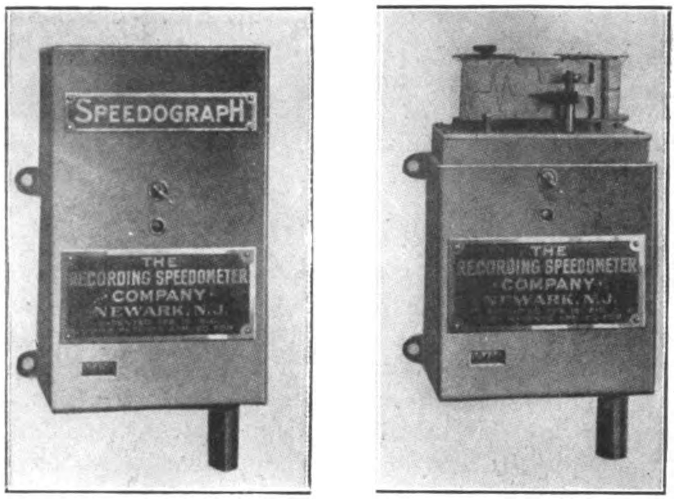


Front View of Travelog, Sealed and with Chart in Place Ready for Installation.

The Travelog is made by W. H. Brown, Rose building, Cleveland, O., and is similar in its application, but makes provision for a whole week's work instead of one day. The mechanism comprises an eight-day Howard clock movement, with actuating parts of cold rolled steel, enclosed in a pressed steel case and secured with a Yale lock. The two last named devices may be located at any point on the chassis, since they are actuated on the principle of vibration.

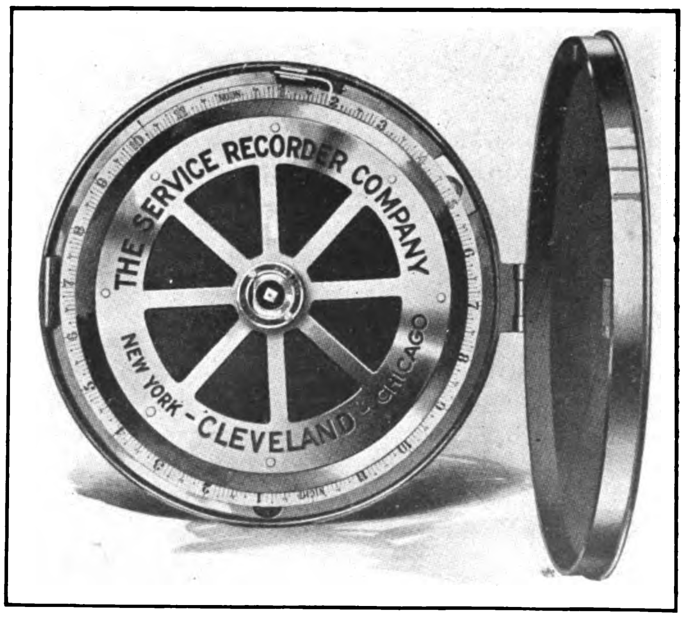
The charts of the Jones, Speedograph, ServiS, Travelog and the Delivery Supervision Company's device present an accurate account of the vehicle all of the time. They will tell when the car left the garage or any given point, how long it took to reach a given destination and how fast it was driven on the way, how long it was detained in loading or unloading, whether or not the driver loitered on the way, whether he put on undue speed at any time in order to make up for avoidable delays.

Most of these recording devices are sold outright, but the product of the Delivery Supervision Company is rented, it being in effect a part of the concern's system of furnishing general supervision over the haulage proposition placed in its charge. In addition to the charts, or tapes, upon which the record is made by the instrument, this system includes a series of uniform reports covering the analysis of these records. It is maintained by the company that the chief importance of a recording device of this character lies in the information afforded, which becomes of value only when it is presented uniformly and systematically. When the analysis is made by a disinterested third party it will be conceded that there can be no possibility for questioning the evidence submitted.



Speedograph Opened and Closed, Showing Pencil Making Record on Tape.

Little attempt has been made herein to do more than suggest the ways in which the various devices and systems may be applied. That they are accomplishing the object for which they were designed is evident from the increasing uses to which they are being put. They offer the means for solving almost any problem with reference to the economical and efficient operation of the vehicle, and are possible of being made to conform to the varied needs of the man who is seeking reliable information of this character.



ServiS Recorder, with Chart in Position for Recording.

POSTAL COLLECTIONS WITH MOTORCYCLE.

THE work of a motorcycle van used for collecting mail at Springfield, Mass., is being observed with extreme care by Postmaster L. C. Hyde of that city, who is to make reports to the Postoffice Department of the national government, for much importance is attached to the service that can be obtained with the machine. The outfit was built by the Hendee Manufacturing Company, with a view of the particular requirements for mail collection, and while it may be possible to improve the body or box for carrying the load, the machine itself is a standardized seven horsepower twin-cylinder motorcycle, fitted with the auxiliaries furnished with all fully equipped vehicles.

The motorcycle has been equipped with a regular 1913 Indian sidecar chassis, but instead of the usual seat and footboard a metal compartment or enclosed body has been installed, which is 40 inches length, 19 inches width and 24 inches height, and which is estimated to have a carrying capacity of 300 pounds. The

Indian Motorcycle Van Now Used for Night Mail Collection at Springfield, Mass.

body is substantially built and the top or cover is slightly curved to afford drainage in the event of rain. There are three openings into the body, one of which is in the top at the rear, through which it is intended that the mail collected shall be deposited. A chute from this opening carries the mail forward by gravity so that it is received at the forward end and then through the motion of the van is carried back toward the rear of the compartment. Under the chute is a small compartment for carrying tools and parts that might be needed.

At the bottom of the forward end is a third opening, and the cover or door may be dropped to unload. Guides at either side of the cover prevent the mail being scattered, and the mouth of a mail pouch may be placed about the door, which then becomes a spout or chute through which the mail may be quickly pushed into the bag. It is used for night collections, taking the place of one horse wagon in what is known as the "Hill district," and is operated by a carrier who was given opportunity to become reasonably experienced before work was begun. The carrier leaves the postoffice at 9:45 in the evening and returns at 12:40, being allowed practically three hours for the trip. Four horse wagons were used before the motorcycle was placed in service, but it is believed that its speed will permit the increase of the size of the collection districts and the use of three machines.

The expectation is that the carrier will be able to drive close enough to the mail boxes located on the edge of the sidewalks to collect from them without leaving his saddle, and the opening of the body is located so that he may deposit the mail conveniently and without loss of time. As the engine may be left running while the machine is stopped there is no delay in starting. The van was ordered by the Postoffice Department for the experiment and it was designed for the work. It is claimed by the manufacturer that the power is sufficient to make the collection round under any weather condition, and if this is realized it is extremely probable that machines will be ordered, not only for this service, but for the collection and delivery of parcels post. The motorcycle will be practically on trial during the winter and if it measures up to expectations it is probable that others will be placed in service, not only in Springfield, but in many other cities throughout the country. For this reason the trial is of particular significance to the manufacturer and to the postal authorities.

TRACTOR REPLACES HORSES.

Maine Agricultural Experiment Station Finds It Almost Indispensable for Farm Work.

An automobile plow and tractor which was put in service at Highmoor farm, the Maine agricultural experiment station, during the last summer, has proved the worth of such vehicles in farm work. The tractor was purchased of the Hackney Manufacturing Company, St. Paul, Minn., and all kinds of plowing was done during the season. In the orchards, work that formerly took horses five and six days to perform, was done in two days by the tractor.

Two sets of harrows are used at once on the machine, while one set could not be pulled by a pair of horses. Stone was carted from fields, the loads being such that four horses could barely move them. In a nine-hour day the gasoline consumption varied from 10 to 14 gallons and from six to eight quarts of lubricating oil were required. With the machine more work was done than with eight horses. By changing the drivers the tractor could work from 15 to 18 hours a day and in a 14-hour day it performed more work than 12 or 15 horses. The Maine officials will use the tractor next year as it been found almost indispensable in the work of the experiment station.

ELECTRIC VEHICLE HAULAGE ECONOMIES.

Facilities That Afford the Greatest Possibilities of Motor Delivery Service Developed by F. A. Poth & Sons, Inc., Philadelphia's Largest Brewery--An Ideal Combination, Sufficient for All Probable Expansion.

By William W. Scott.

THE possibilities for economizing highway haulage are generally limited by conditions over which the business man has no control. No organization will prevent retardation of traffic from congestion of the streets or the roughness of their surfacings. Unless there is a very cogent reason no change can be expected that will facilitate the handling of the loads at the point of delivery. While it is certain enough that any one of these factors is of sufficient importance to receive the serious consideration of business men individually and collectively, and there is no question that each will eventually be given the attention it deserves, it is very apparent that betterment can only be accomplished by regulation and co-operation.

Part of the Combined Loading Shed and Garage of the Brewery of Frederick Poth & Sons, Inc., Philadelphia, Penn., Showing the Platform and Spur Track at the Right; at the Extreme Left, Beyond the Line of Posts, Is Storage Space for a Full Row of Vehicles.

Because of these limitations there is greater reason why nothing that will yield economy of highway transportation shall be neglected. The factors that can be considered with practical certainty of economy are the increased speed and the greater load capacity of the motor vehicle, and the actual handling of the freights carried. While any one of these may be reasonably productive when a common sense method is adapted, it is obvious enough that the most economical system will be that which will realize the possibilities of all.

It is not practical or possible to develop haulage economy without the exact knowledge that comes from accounting. It is necessary to know every detail of work accomplished and item of expense to make even intelligent comparison of the value of two methods of transportation, and it is only by possessing and utilizing this information that high efficiency and economies can be insured.

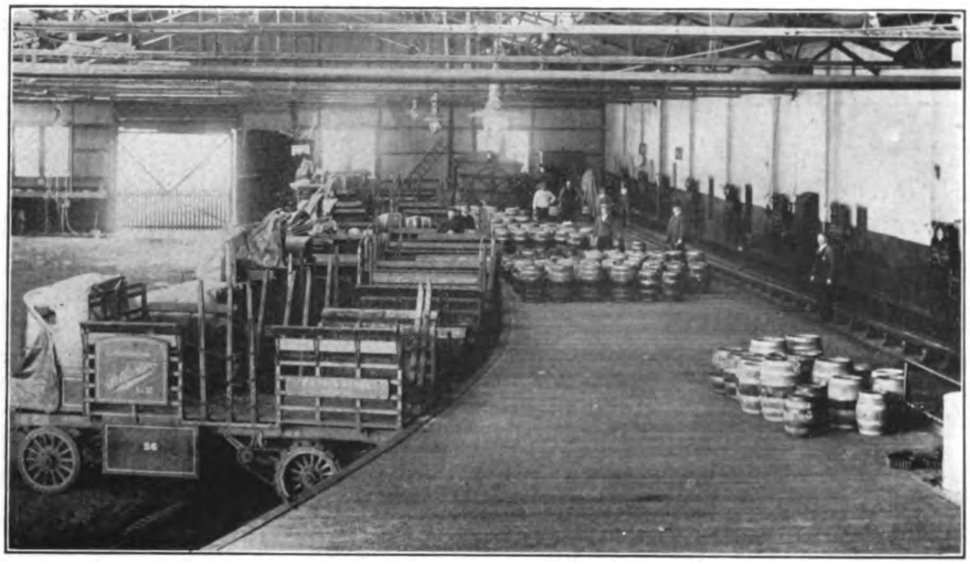
In some instances practical business men have regarded the facilities for loading and unloading of quite as much importance as the vehicles and the system by which they were operated. While this is undoubtedly a view that is entirely justified, it is a fact that the use of motor vehicles is, with most business concerns, still looked upon as an experiment, and there is not the confidence obtaining that would impel the expenditure of large amounts to make changes in facilities.

It can be safely stated that wherever facts have been established by careful accounting, and there is positive knowledge of the economies, expenditures have been made that may seem very large, and yet are considered to be in the nature of conservative investments. Probably the best examples of development of economic transportation are those of concerns having experience extending over considerable periods of time. Not only this, there has been a desire to adapt a service to meet any condition and to ascertain the possibilities of any idea that seemingly had merit. Generally speaking, the purpose has been to improve

the service and to lessen the expense, but not to sacrifice in any way through unwarranted expenditure.

While it cannot be said that any one instance is a rule by which to measure the general application of a theory or principle, it will not be denied that when a service and facilities have been determined with extreme care it may be depended upon as having qualities that command the attention of business men.

The experience of Frederick Poth & Sons, Philadelphia, Penn., which is the largest brewing firm in that city, with motor vehicle delivery service, is of unusual interest in that this concern has eliminated all save 14 horses from its delivery and replaced them with trucks and wagons, and it has provided what are probably the best facilities in the country to secure from its machines the greatest measure of economy. The transition was not accomplished in a short period of time. In fact it has extended over a term of 10 years, and every change was determined only after careful study and observation that would conclusively establish its economic value to the company.



The Loading Platform and the Conveyor by Which the Kegs Are Carried to the Waiting Trucks, Where 26 Machines Can Be Loaded at the Same Time.

More than 10 years ago the firm purchased a five-ton electric Vehicle Equipment truck, and began its operation. At that time the brewery stables contained about 175 horses. The production has always been sold in kegs and barrels and the customers have been principally in the city, although there is a small part that is shipped to patrons within a radius of perhaps 30 miles. While the business has increased to some extent during the decade there has been no large development because of the absence of competition such as may be found in other localities. That is, there has been a reasonable and satisfactory growth, but it has not been a result from a campaign directed toward other brewery products.

Today the company has in its service 32 electric machines, of which 30 are General Vehicle wagons and trucks and two are products of the Commercial Truck Company of America, a Philadelphia concern, and two five-ton gasoline trucks. Three more electric trucks have been ordered and these will be delivered in a short time. There are now in the stables of the company 14 horses, two of which are used for driving purposes and the others for delivery, but when the three trucks ordered are received it is expected that all of the horses will be eliminated from the service. It will be seen that the motor wagons and trucks have each replaced an average of about five horses, though the vehicles range from one ton to five tons capacity. The sizes are as follows:

One-ton, electric	5
Two-ton, electric	4
Three-ton, electric	8
Five-ton, electric	15
Five-ton, gasoline	2
Total	34

Of the electric machines one three-ton and one two-ton are Commercial vehicles, and the remainder were built by the Vehicle Equipment and the General Vehicle companies. One of the gasoline trucks, a Pierce-Arrow, was delivered last April, and the other, delivered in May, is a Mack. These are the only explosive engine motor trucks that the company has owned.

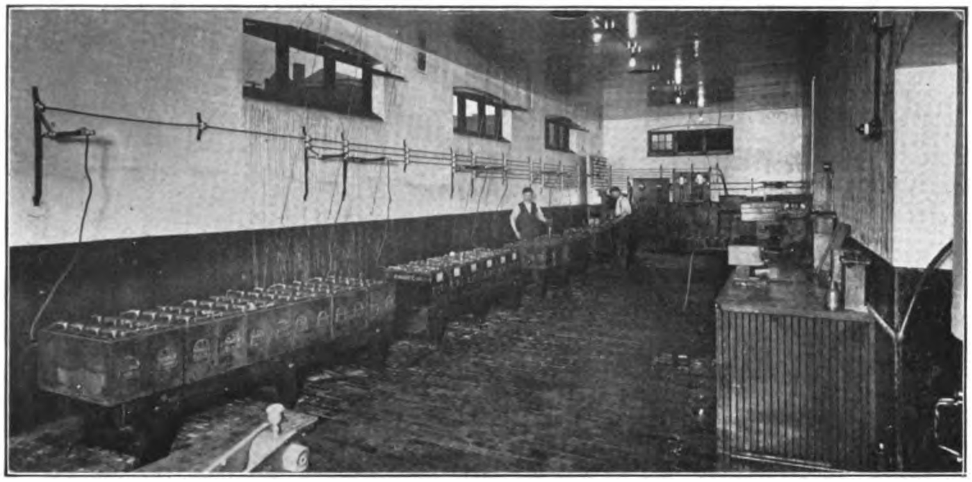
The plant of the company is on either side of Jefferson street, between 31st and 32nd streets, and on the north side is the storehouse, the stable and the loading shed and garage. When the storehouse was built it was with no expectation that the horses would be replaced by motors. The ground rises rapidly north of Jefferson street and the level is perhaps 15 feet above the street at the rear of the storehouse. The Jefferson street frontage of the building is unbroken, but entering through a large gate one reaches a court of considerable size with the storehouse and the original loading platform at the right, and at the left a building with the lower portion designed for a garage or wagon shelter, and the upper or second story intended for use and equipped as a stable.

The arrangement of the buildings was extremely advantageous. The centre of the court is open and the ground is paved and well drained. The purpose was to have the wagons and trucks within the court, with access to the stable by a runway. This construction was with a view of sheltering the men and animals when loading and unloading, as well as to making it convenient to hitch and unhitch the teams. There was another run from the stable to 32nd street. As the loading platform was limited in size and it was not possible to have all of the teams in the courtyard at one time the loading could not be carried on simultaneously and it was necessary to relay the trucks

into the court. As all of the vehicles did not return at the same time they could be unloaded with practically no inconvenience or delay.

When the first electric truck was placed in service this was kept in the garage off the court. As this section of the building facing the court was open, but could be closed by curtain doors, it was gradually given over to the machines until its capacity of 16 was reached. For the purposes the garage was all that could be desired, there being sufficient light, and a large canopy in front extending the entire length, and it was well heated in winter. The battery room was located at one end of the garage. When the first electric truck was installed and it was found to be a satisfactory vehicle the company planned its garage service. It produced its own current and with the machine facilities of its own shop and the services of its machinists always available, it was believed that motor vehicles could be used to excellent advantage.

The first experience of the company was, like that of many other concerns that have used motor trucks for a long period, not economical or satisfactory, which was due largely to the inability to obtain men competent to maintain the machines and the batteries. In 1904, however, A. Stevenson, who had had a thorough training as a machinist and considerable experience with automobile construction and repairing, was engaged as garage manager, and from that time the company has been exceedingly well served. At that time the number of wagons and trucks in service was few as compared with the present equipment.



Interior of the Battery Room of Poth's Brewery Garage, Equipped to Charge Four Batteries at a Time—An Ideal Installation.

In experimenting with the electric machines they were worked consistently on routes that had been served with horses and the character and volume of the service was carefully noted. There was no desire to accept anything as a fact until it was demonstrated by results and this applied to every detail of cost of operation, maintenance and upkeep. The expense of delivery was figured on the basis of a barrel, which permitted absolutely accurate comparison for both animal and motor vehicles. But cognizance was given to the fact that there is a greater average cost with a small number of electric machines than with a large installation, and a reasonable allowance was made.

The routes served by the regular delivery service of the company are decided by Frederick Poth, and as his supervision of this work has been for a number of years, and has included both animal and motor vehicles, his judgment has largely determined the form of equipment. Mr. Poth has been a motorist for years and this experience has been of decidedly practical benefit. The possibilities of animals and electric machines have been determined through service for as long a period as was necessary to reach absolutely dependable facts, with reference to each specific instance. Mr. Poth made comparisons of service under all conditions of operation, and his observation may be said to be constant. He personally observed the results from trials and experiments and has first hand knowledge of such influences as may have bearing upon efficiency.

Philadelphia as a city covers a large area and the topography may be regarded as moderate so far as gradients are concerned. The city is 14 miles in length and seven in width and there are about 1500 miles of paved streets and 500 miles of what may be regarded as road in the suburban sections. There is a ridge between the Delaware and Schuylkill rivers, and this must be ascended or descended. Arch and Market streets, two of the main thoroughfares, have paving that is ideally smooth, but the other paved streets by no means compare with them. While the surfaces may be considered good when contrasted with the streets of New York or Chicago, both of which are notoriously poor, they suffer by comparison with the highways of many other cities, but principally from their roughness, which is destructive of animals and vehicles alike.

Outside of the city are numerous suburbs, and to these delivery is made. The route that serves Chester and Bristol covers from 48 to 53 miles, and the road to Bristol is very hilly. This is particularly true of that part of the highway that reaches Busselton. The direct Chester road may be regarded as fair. The Clifton Heights highway is of much the same character as that to Busselton. Chester and Bristol are the farthest points that are served by the regular delivery.

Before the number of electric wagons and trucks in service had reached the capacity of the garage that has been described it was realized that to secure the greatest economy of service it would be necessary to make many changes because the machines must be sheltered. The loading platform was found to be too small and the courtyard could not be advantageously

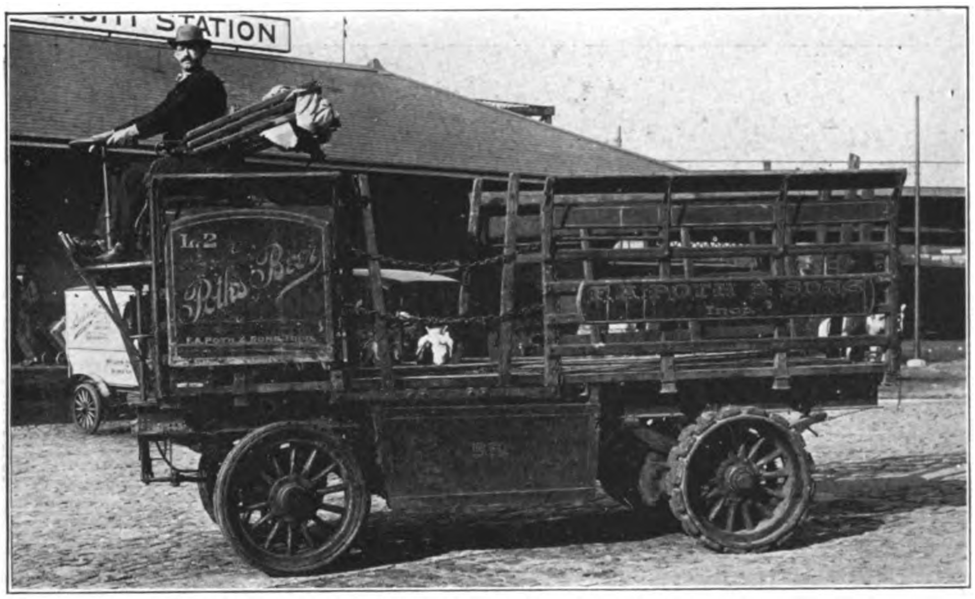
used because of the congestion of vehicles when loading and unloading. To secure the fullest service of the motor vehicles they must be utilized as constantly as possible during the working hours of the day. While there was every reason to believe that horses would eventually be replaced by the machines, the time when this would be realized could not be determined with any degree of certainty.

To make provision for a considerable number of years and to insure facilities that would be adequate for the business it was decided to build a loading shed on the higher level back of the storehouse with a platform extending the entire length of the property between 31st and 32nd streets. This was planned so that the kegs and barrels could be brought from the storehouse by elevators and carried along the platform by conveyors, and to minimize the handling and eliminate the hauling in freight shipments a spur track from the Pennsylvania railroad was included. The platform was built in 1908 and after this was erected it was decided to cover it with a trussed roof of the monitor type and to have large entrances at either end that could be closed with a gate, the whole forming an enclosure that would shelter the entire wagon and truck equipment.

The structure as completed is very substantial, being of brick and steel, with but a single line of posts along the north side. The loading platform was intended to allow 26 vehicles to back to it, and the spur track is of a length that will take eight freight cars under the roof at one time. The surface of the ground is paved to permit drainage and the track is filled with plank so that the vehicles may be handled without difficulty at the platform. At that time there was a runway from the horse stable to 32nd street, and this made it possible to bring the animals to the shed as quickly as to the lower courtyard.

The number of electric vehicles was gradually increased and the horses decreased, and as the capacity of the garage off the lower courtyard was exceeded the machines were housed in the loading shed, and this led to the installation of charging apparatus. Then followed the determination to utilize the loading shed as a garage and to equip it with whatever was necessary to meet the requirements. This was followed by other changes, some of which have but recently been completed, and today the brewery has in this combination facilities for handling its delivery service that are probably not equalled in the world.

The loading shed is sufficiently large to shelter 100 wagons and trucks, and with an exit at either end of the building it is possible to handle the machines with ease and celerity. The vehicles now in use can be arranged in two rows, one at either side, giving the entire floor area between them for whatever purpose may be necessary. In installing the equipment Manager Stevenson departed from the usual custom of a multiple charging panel and located 32 single panels, this necessitating the assignment of a permanent location to each vehicle. On the loading platform side the panels are placed close to the wall of the storehouse, one directly behind each station of the machine it is intended for. On this side are located the first 16 machines to go out in the morning and when they are brought in at night and backed to the platform they are not only ready for charging, but are ready for loading. The charging leads from the panels are carried across the platform. On the opposite side of the loading shed are located the other 16 panels, and these are placed with reference to the machines they are to be used with. When these are ready for loading they are simply turned and backed to the platform. It will be practical to supplement these panels as desired.



The Veteran of the Poth Trucks, a Vehicle Equipment Machine, Bearing the Maker's Number of 362, Fitted with Special Brewery Body.

The value of the single panel is stated by Manager Stevenson to be in the saving of time in going to and from a machine to a single board to make the necessary readings of the indicators, as well as giving the man directing the charging certain information of the condition of the battery, and insuring that each will receive the attention desirable or necessary. Not only this, where exact battery data are sought this individual supervision has been productive of observation that is distinctly valuable. Several months ago the battery room was removed from the old location to an addition built on the loading shed, and this is of sufficient size to perform any work that may be desired. Specially arranged and equipped for battery work the facilities may be regarded as ideal. There is a charging panel where four batteries may be charged at once,

and this permits work of restoration or forming that is at present considerably in excess of the requirements. The room is paved with wood blocks and the floor may be flushed to eliminate the acid and electrolyte that may be spilled in the work.

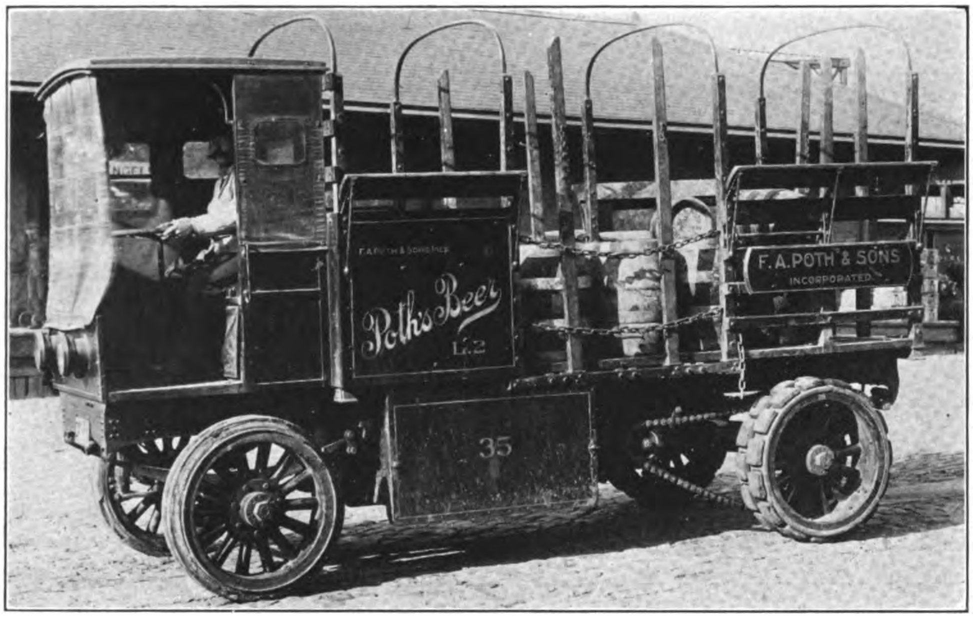
The greater part of the stable on the second floor of the building that was formerly used as a garage has been converted into a machine shop, and a concrete run built so that the machines may be driven from the loading shed into it. As it is arranged seven vehicles may be placed in a line in the centre of the shop with abundant room to work at either side. Here has been installed such machine tools as are necessary, although the heavier work is done in the main shop. This entrance is directly across the loading shed from the battery room.

The loading shed has been more thoroughly enclosed to maintain a sufficient degree of warmth, the roof ventilators have been adapted that they may be closed during the winter, the entrances provided with sliding doors, and a system of piping has been placed and a boiler installed so that the temperature may be kept to a degree that will not affect the efficiency of the batteries or lessen the capacity of the men. At the north side of the loading shed a channel has been made in the floor in which has been laid three large steam pipes. At regular intervals are sections covered with grating and with plank. The gratings are located as to be directly beneath the battery cradles of the machines kept on this side, and in cold weather the pipes are heated. Canvas curtains that reach the floor are hooked on the sides and ends of the battery boxes, and these confine the heat about them and maintain the temperature at such a degree that the capacity of the machines is not lessened. It is possible to regulate the heat to meet practically every climatic condition that could be experienced. The shed is lighted with six big arc lamps.

The loading capacity of the platform is 26 wagons or trucks, and to serve these there are two conveyors from the storehouse located nearest to the 32nd street end. The one of these carries the kegs or barrels the length of the platform, and the other serves the end only. The loading is begun at 6:30 in the summer and 7 o'clock in the winter, and a half-hour before the drivers report the conveyors are started and the platform is filled when they arrive. The shipping clerk's office is located on the platform and here the orders are received and the requisitions for vehicles are made out. No machine is ever sent out overloaded. Should the load be excessive the responsibility would be upon the shipping clerk, who directs the loading in the absence of Manager Stevenson. If Manager Stevenson is present he usually passes upon the requisitions. He decides what vehicle shall be sent out in the event of a load being larger than the machine usually used by a driver will carry. If the order for a route is so large that it will overload the wagon usually sent out on it another is assigned. If the load is less than what is ordinarily carried a change may be made. The driver is kept on the work regularly because he can probably better handle it than one less familiar with his customers, but he may have different machines whenever in the judgment of the manager it is best to make the change.

With this system of supervising the loading there is no uncertainty about the weights carried and it is possible to have the vehicle capacity where it will be serviceable. The only exception to this rule are the gasoline machines, which are operated regularly on the long suburban routes. The advantage of this method is that no matter what the variation of orders may be the fullest capacity of the entire equipment may be utilized, and there can be no question of the value of placing the responsibility entirely on the man who knows best what each machine can do. After the first loads have been sent out supplementary orders are received and these are delivered with such wagons or trucks as may be available, these being selected for the work with reference to their battery capacity. This is an insurance against loss of time through battery exhaustion, because the batteries are tested when the machines are brought back to the garage and their condition so far as power is concerned is definitely known.

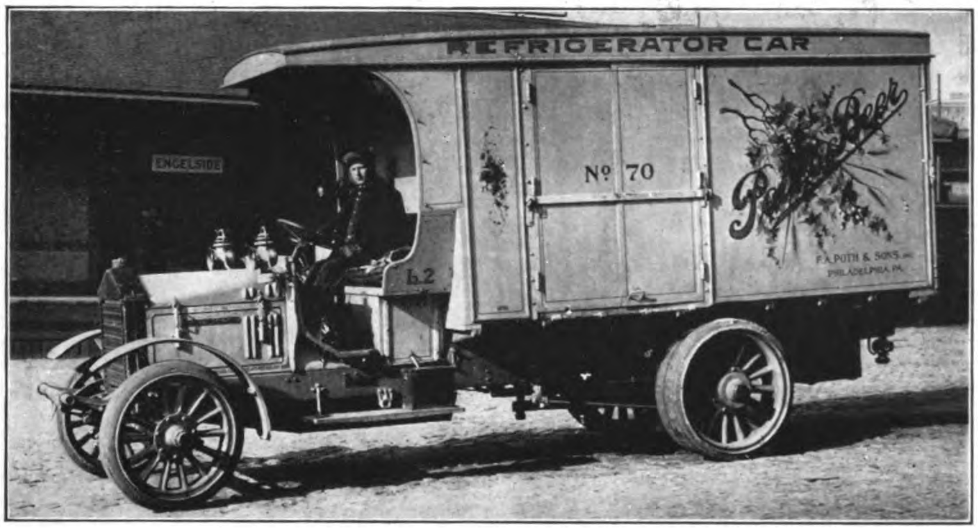
The loading is always done to a system, and this requires the drivers to assist the drivers of the first three trucks to be started, and with these out of the



The Latest Addition to the Poth Service, a General Vehicle Truck with an Unusual Body Equipment to Protect the Load and Driver.

way the men individually load the machines they drive. If more than one load is taken out the driver does his own loading. As the kegs are carried along the platform by the conveyor they are rolled off by the drivers, who select the number of each size they are to carry out. The kegs are then placed on end back of each machine and are ready for loading. When the trucks return with loads of empty barrels these may be carried into the lower courtyard, where they are unloaded and are washed and sterilized, or they may be unloaded at the loading platform, where a conveyor carries the kegs to the courtyard. In this courtyard the trucks are usually washed with a hose and cleaned from mud and dust. The equipment is always well kept and its appearance is a source of pride with the company.

One particularly interesting body installation is that on the Pierce-Arrow chassis, which is used on the Bristol route. This is an enclosed type that may be loaded at the rear or at either side. The doors are tight fitting and the entire body, roof, top and sides, is lined with thick sheet cork. The purpose of this insulating is to keep the beer cold on the long route during the heated periods. It is stated that it is possible to carry beer in this truck for several hours without a sufficient increase of temperature to affect it, the kegs being loaded from the storehouse at a degree not much above freezing. Prior to the building of this body the beer was protected with canopies and tarpaulins with not always satisfactory results.



Side and Rear Loading Enclosed Refrigerator Body, Lined with Cork to Maintain an Even Temperature for Loads Carried Long Distances on a Pierce-Arrow Chassis.

The drivers finish their work for the day from 4:30 on and by 7 the trucks are practically all in the garage. After they have been washed they are backed to their respective stations and the charging is begun at once. The company produces its own current and this is supplied at from 30 to 35 amperes. The main line voltage is approximately 120, but with the series of batteries connected this will be reduced to about 109 by the resistance. The charging is usually completed about 2, and in cold weather the batteries are again connected for a short time in the morning before loading to increase the temperature and establish the capacity as near normal as is possible. In the "boosting" the voltage is increased to about 130, and the amperage is approximately 20. Saturday nights the batteries are charged to the line voltage at 25 amperes, and Sunday nights they are again connected and charged at low voltage at from 18 to 20 amperes until morning, this giving an overcharge that is desirable to establish certainty of capacity and neutralize sulphation.

The batteries are carefully maintained. When new they are installed in the machines from which the largest mileage is expected and as the capacity is reduced with use they are changed to vehicles from which less work is required, and this process is repeated until the battery is no longer serviceable. As a rule all of the batteries used are built, the material being purchased and used as needed. The rebuilding and maintenance work is considerable and the attention is systematic. Each battery is equalized once a month and it is customery to cut out a cell at that time and ascertain the condition. If there is defect or loss of capacity the cause is located and the restoration made.

The garage day organization under Manager Stevenson consists of an electrician, two machinists and a battery man and a helper, but he is also responsible for considerable other work outside of the garage and the entire time of the electrician and the machinists is not given over to the wagons and trucks. The night force consists of a mechanic and a helper who care for the machines, the mechanic supervising the charging and the helper oiling and greasing them. The facilities for repairing and maintaining the machines are all that 10 years' practical experience can suggest and by carrying a comparatively small stock of spare parts practically every exigency is provided for.

The records kept include the mileage of each vehicle and the wheels and tires with which it is equipped. The wheels are numbered and they are followed if changed from one machine to the other. The tire record shows the number of the wheel on which it is used and the mileage can be established by the daily total taken for each machine. The record of each battery is kept by miles, so that it is possible to learn the work performed up to a given time. Each machine is equipped with a service recorder, which shows the number of miles driven, the speed at any time, the number of stops and the time of each, and these records are filed after the data have been supplied with reference to tires and batteries. The average work is approximately 35 miles daily for the five-ton machines and 41 for the three-ton trucks, which is

practically the maximum service expected from them. The battery records show all of the work performed upon them so long as they are in use and the salvage from old material returned to the manufacturer. The labor of the electrician and the machinists is specified and the requisitions for stock and material of any kind indicates the cost of maintenance aside from the labor. The charging record shows the current consumption, which is charged at the cost at which it is produced. In the accounting the overhead charges are established and it is possible to determine with great accuracy the expense of operating the service and the delivery on the basis of a barrel. In the long hauls the gasoline service is kept separately so far as service records are concerned, although it was once included with the other machines when the electric trucks were used and from 48 to 53 miles were made daily by two machines which were equipped with two batteries each connected in multiple. There is a gasoline storage system of the hydraulic type in the garage and the record of fuel and lubricant for the gasoline trucks is also separated from the electric.

The streets of the old section of Philadelphia are narrow and traffic in them is often congested with considerable delays at times, and as delivery from the vehicles cannot be expedited, there are limitations to the economy of time that cannot be changed with any form of transportation. In the development of its service the management of the brewery has made every provision for improvement that experience could dictate, and the value of the motor truck as compared with animals is best shown by the practical elimination of horses.

As to the measure of economy that is obtained through the use of motor trucks and wagons, if one considers the expense since the first machine was installed and on this basis makes his estimate it is probable there will be no saving as compared with horses, but if the work that is now accomplished is placed against animal service it is certain that the cost would be decidedly smaller. And it is well to point out that with the increase in the number of machines the average cost of operation is lessened.

NEW MOTOR TRUCK WHEEL.

Boston Inventor Seeks Factory Location in Fitchburg, Planning Production in Near Future.

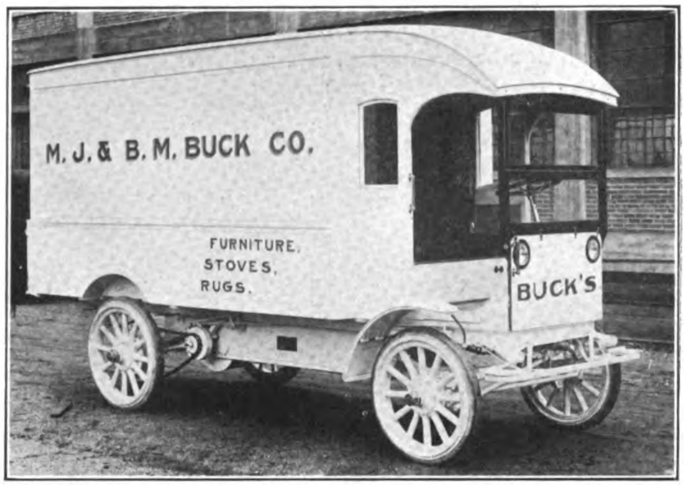
Joseph H. Symonds of Boston has invented a new style wheel for commercial motor vehicles and at a recent demonstration of the device it was thought by business men of Fitchburg, Mass., to be practical. A truck or delivery wagon will be manufactured having as its chief recommendation the wheel designed by Mr. Symonds, who has been in touch with R. D. Redfern, industrial secretary of the Fitchburg board of trade, with a view to locating the factory in that city.

The old Becker machine shop at Water and Newton streets was recently inspected by Mr. Symonds and Mr. Redfern and it was agreed that it would make an excellent place for the manufacture of motor vehicles. This site will be chosen if it is decided to manufacture the machines in Fitchburg. It is proposed to interest local capital in forming a company and it is stated that all of the patents are in such shape that the work could be started within a very short time. W. F. Magill of Boston, who is associated with Mr. Symonds in his business, says that already a large number of orders have been received.

AN IMMACULATE FURNITURE WAGON.

Details of Detroit Electric Vehicle Placed in Service with Buck Company in Lansing, Mich.

An extremely attractive and pleasing vehicle is the 3000-pound Detroit electric chassis that has been placed in the service of the M. J. & B. M. Buck Company, furniture dealer, at Lansing, Mich. The chassis is the standard type, equipped with a 60-cell Edison



Detroit 3000-Pound Electric Chassis, Fitted with Special Enclosed Body for a Lansing, Mich., Furniture Dealer.

battery, and on this has been installed a covered body that is specially designed for carrying loads of large bulk. The construction is extremely wide and semicircular recesses have been made in the floor and sides above the rear wheels to provide for the body movement when the vehicle is loaded.

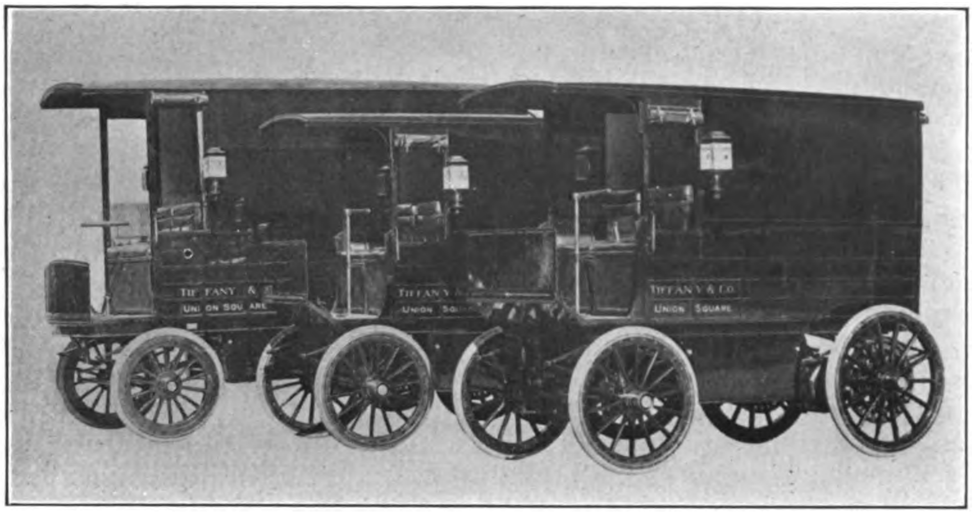
Forward of the body is the cab, which is the width of the chassis frame, with side panels the full depth of the seat. In these panels are windows, which afford an excellent view at either side. The roof of the body covers the cab and curves sharply downward to the height of the top of the windshield installed upon the dash, the lines of the sides and front being especially harmonious. The protection for the driver is unusually good, and the machine may be said to be equally well adapted for extremes of temperature and storms. The wagon is one of two or three that have been fitted with a panel body. The design is enhanced by being finished in egg-shell white, with a dainty outline of color and attractive lettering.

ELECTRIC VEHICLE PRACTISE.

Sound Engineering and Experience with Service Conditions Develop Capacity and Endurance of Machines---Battery Improvement a Large Factor for Increased Economy---Possible Sources of Power.

By William W. Scott.

TAKING up American productions in practically their order of appearance it will be seen that the Riker and the Electric Vehicle companies have ceased to exist, and that the Riker principle of double-motor propulsion was adopted by the Electric Vehicle Company, at least on its heavy machines. The use of two motors simplified the rear construction so far as it eliminated the compensating gear, but it was not believed to be as economical of current as the single motor, and complicated the power wiring. However, both Riker and Electric Vehicle machines are now in use and in some instances do exceedingly important service, with a reliability after 10 years' operation that is decidedly surprising. From every aspect the construction has been satisfactory, and it can be said that had the engineers been as confident of the possibilities with these machines it is doubtful they would have turned to any other. In fact it may be said that the endurance of vehicles of this design, well maintained and systematically cared for, is not yet known. So far as the conservation of power is concerned it should be known that in many instances these machines were built without the roller and ball bearings so generally used today, and in instances where such bearings have been supplied there is but comparatively little difference in the current consumed.



Three Vehicle Equipment Delivery Wagons, Delivered to Tiffany & Co, New York City, in 1901, That Have Been Used Daily Since That Time.

In the development of the electric delivery wagon there have been two distinct paths for endeavor, the one being the storage battery and the other with the vehicle construction. These have been pursued by different engineers, each more or less dependent upon the other. By this is meant that the vehicle designers have desired batteries of comparatively light weight and large capacity to minimize the load of the machine and to obtain the power that would increase the radius of movement. The need of reducing the losses through friction has been a problem for the designers only. They accomplished this in some of the early vehicles by the use of ball and roller bearings. Battery development was something with which the vehicle men had nothing to do other than to afford the benefit of their experience to the builders of batteries.

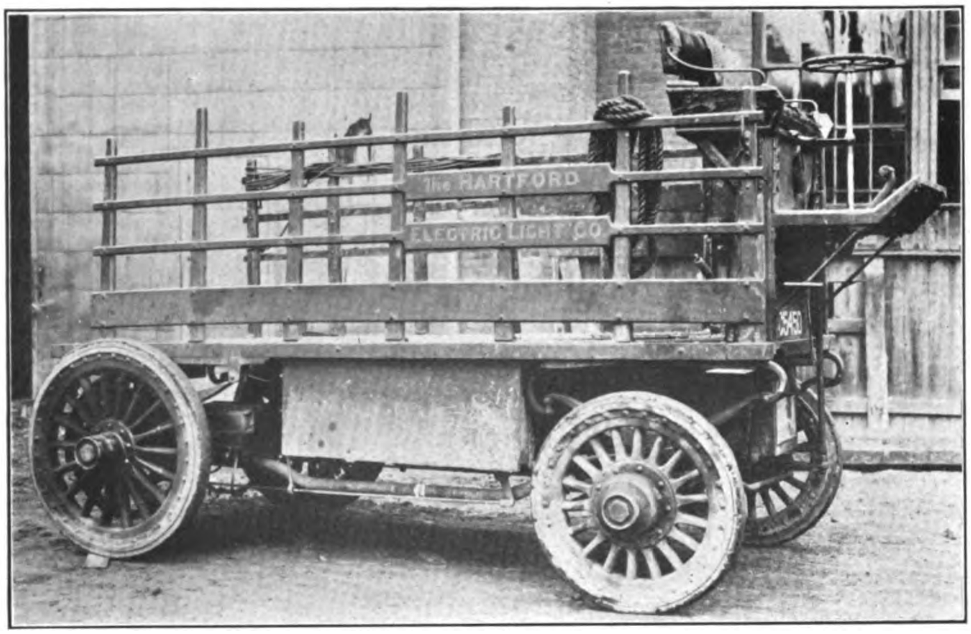
The basis of evolution may be found in the first foreign and American machines, and it will be understood that chain and direct drive were originally given attention. The first gasoline machines were generally chain driven and later on came the application of the shaft drive by Renault Freres in Frances. The success of this form of power transmission directed attention to its use. But there were other possibilities, which were experimented upon, and these included the following: The drive by a single reduction accomplished through a herringbone gearing; by a double reduction through a countershaft and single chains; by a single reduction through a shaft, countershaft and side chains; by a double reduction through single chain to jackshaft and side chains; by a shaft-driven worm gear; by a motor incorporated in the rear axle housing and driving through spur gearing to internal gears within the wheel rims; by two or four motors fixed to the axle spindles and driving by armature shaft pinions meshing with racks formed in the inner peripheries of the disc wheels; by two or four motors fixed or pivoted to the axles and driving through pinions to internal gears bolted to the wheel hubs. The last two methods of drive may be applied to either front or rear or all four wheels, and with the first of these a gasoline engine is sometimes installed to drive a generator whose function it is to keep the battery constantly charged.

All these transmission systems have proven to be efficient and satisfactory in practise. The shaft drive, however, is generally adopted for pleasure vehicles and the majority of the service wagons are driven by single motors with either chain or shaft connection with a countershaft and side chains. In some instances the drive from armature shaft to countershaft is by a silent chain, sometimes encased and operating in lubricant, and occasionally exposed. The differential with the double chain designs is incorporated with the jackshaft, and with the shaft, worm and herringbone gear driven machines it is a part of the rear axle. Where the direct shaft is the means for transmitting the power the rear axle is generally of the semi-floating type.

The preference is given by designers to the dead rear axle, the single motor and the double reduction by chains through jackshaft and sprockets, because it affords the most substantial construction, and there is not the disadvantage of carrying a large weight on the axle, which is subjected to very severe stresses when the vehicle is loaded. It should be remembered that simplicity is the one object sought by the builders of electric vehicles and with this a purpose to minimize frictional losses through the use of roller or annular ball bearings. It is assumed that the fewer the bearings the less the probable wear, and so far as this may be done the bearings are protected from abrasive substances.

It is extremely improbable that the designers of the service wagons built from 1898 to 1905 realized the excellence of their vehicles. It may be said of some of these machines that they were heavy, but the weight was largely due to the batteries and the ample margins of safety provided, for special metals were not so generally utilized as now, and the qualities were by no means as certain. Not only this, there was not the same certainty of endurance as now. By the use of high class material it is entirely practical to reduce weight and yet have greater strength as compared with the wagons built during the period stated. But some surprising illustrations of endurance are afforded by wagons that have been driven constantly over the extremely poor streets of New York. Several of the wagons operated by the New York Edison Company have been in service for 10 years, one has been used by Frederick Loeser & Co., for 11 years, one has been used by Stern Brothers for nine years, three of the fleet of Tiffany & Co., were delivered to that firm early in 1901, three of the machines owned by Arnold, Constable & Co., were delivered in 1903, one of the Riker wagons built for B. Altman & Co., in 1898, is regularly used, and one might go on indefinitely and specify vehicles that have been worked practically all the time. Probably one of the best examples of endurance is the Riker two-ton wagon that was paid for by the Hartford Electric Light Company in March, 1901, and which was delivered at least at that time. This wagon has been used constantly for all kinds of haulage and it is in such condition today that a new battery was recently bought for it, which indicates that the owner believes it will be serviceable for a couple of years more. The F. A. Poth & Sons Brewery at Philadelphia, Penn., is using daily a truck delivered 11 years ago, and so far as indications go it is just as reliable and does quite as good work as it ever did.

The work that these machines can do is larger than it was originally, because of the greater battery capacity, and compared with the results obtained with the vehicles of the latest design and construction the efficiency of the wagons is decidedly surprising. The mileage of the light types will average as high as 45, and generally more. There are in the New York Edison Company's service rebuilt Columbia surreys, that are now trimming wagons, that do 50 miles or more each night, and Stern Brothers' truck makes 40 miles each day in transfer work with a slight "boost." The veteran of Frederick Loeser & Co.'s delivery service averages a daily run of 32 miles in transfer work. None of these machines may be considered fast, but each is equal to the requirements.



Two-Ton Riker Wagon, Delivered to the Hartford Electric Light Company, Hartford, in March, 1901, That Has Been Used Constantly Since That Time and Is Still Considered Good for Several Years.

Regarding highway haulage from any point of view, while there may be a desire to haul loads of large capacity quickly it is a fact that the proportion of light wagons far exceeds those of the truck type. It can be said with certainty that this condition will

not be changed, no matter what the form of conveyance, although the ratio may differ from time to time. While the first delivery wagons were merely with closed bodies installed on pleasure carriage chassis, the possibilities of the electric vehicle for transportation were first practically developed by Andrew L. Riker, who, after his delivery of six small wagons to B. Altman & Co., built a five-ton truck for a wine importing firm in New York. This was at that time the largest machine ever produced and it was equal in capacity to the biggest standard vehicle of today.

If this machine served no other purpose it was an example for other builders of wagons, and it may be said with truth that the service it afforded was carefully observed and demonstrated the possibilities of motor vehicle transportation better than any other machine then available. There is no doubt that the actual value of that construction was not understood or realized, and yet the one surprising fact is that there has been so little change when the new productions are compared with the old.

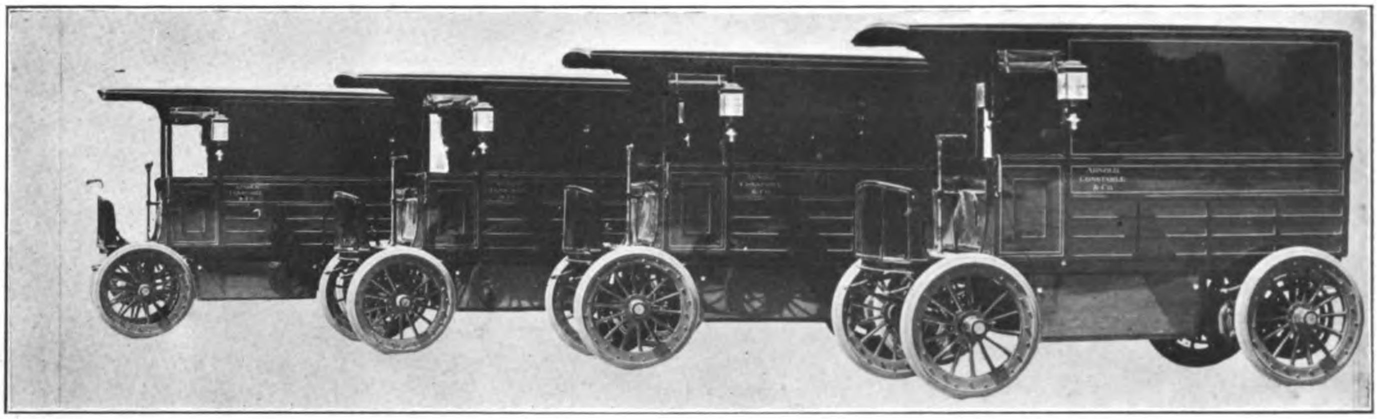
There should be no misunderstanding relative to the actual results obtained from electric vehicles. Originally installations were generally made because of the advertising value of a new or attractive form of delivery. Perhaps a few persons were satisfied that the electric wagon was practical and looked forward to the time when there would be development that would establish this fact. In experimentation, expense of operation and endurance were not seriously considered. Mechanical practicability was the one object sought. This result having been attained, actual service demonstrated that the electric machine was superior to the animal, but the cost of operation was large. There were many reasons for this.

The initial or purchase price was relatively larger than now. Batteries were costly, heavy and of comparatively small efficiency. Charging stations were very few and the cost of electric energy was large. The motor was believed to be a machine of uncertain quality and the battery was regarded as a mystery. Batteries then required a greater degree of attention than they do now and expert batterymen were not very numerous and in good demand.

The vehicles utilized for pleasure were generally looked upon as expensive creations, the toys for those who had resources and time to devote to them. With many they served to amuse for a time and passed from the one to the other. With the machines built for service purposes, however, they were measured by the cost of haulage by animals, and considering every expense they were not attractive propositions when economy was the main object sought. Besides the garaging problem was serious. The purchaser of a machine found it necessary to provide equipment that was regarded as expensive, operating conditions developed that necessitated expert attention, and, worst of all, there was apparently belief that an automobile vehicle could be neglected and still remain serviceable. Those who bought machines as business wagons demanded service, and it was necessary for the manufacturers to meet every conceivable problem and reasonably satisfy the owners.

The manufacturers of batteries developed their products decidedly. This progression has been comparatively rapid. Weight has been decreased and capacity increased, and durability has been secured to a surprising degree. In every respect improvement has been made. Not only this, but cost has been lessened. Instead of only the acid or lead battery, the Edison alkali, or nickel-iron battery has been developed and it is found to have qualities widely different, one of these being its extremely long life or period of service, and another is its durability. The improved batteries had the result of increasing the quality of service and the economy of the vehicles. Capacity and mileage were increased.

During the period from 1900 to 1910 it may be said that the electric vehicles were well tried and experimented. The number in use increased annually, but there were few concerns that produced them in considerable numbers, and only several that built service wagons exclusively. In the larger cities they were the most used because of the better facilities for charging and garaging. Some concerns having large requirements for haulage and delivery experimented with them. Some owners produced the current used. In New York and several other cities exclusive service wagon



Four Vehicle Equipment Delivery Wagons Installed in 1903 by Arnold, Constable & Co., New York City, and Operated Daily in Regular Service.

garages were established. There was no special encouragement given those who used the vehicles, other than the practical results obtained.

Then there was a decided awakening to the practical value of the electric vehicle. Firms of large magnitude, that had used one or several for varying periods, began to add them to delivery equipment and to replace horse vehicles wherever the hauls were not of extreme length. Public service corporations furnishing electric energy, commercially realized the business possibilities through promotion of the use of these machines. A considerable number of the central stations adopted electrics for their own service and several have established garages where systematic care and attention can be given those who have one or more vehicles, yet whose equipment is not sufficient to justify establishing a private garage. There are today in the United States about 150 central stations that have in service from one to 100 electric wagons and carriages of different types. Some of these are using gasoline vehicles as well, but wherever it is possible the electrics are used.

In the United States there are approximately 30,000 central stations which can be a source of supply for electric energy for vehicles. Some of these serve large areas and some have established sub-stations where vehicle charging is done. It is entirely within possibilities for charging stations to be located at such frequent intervals that touring could be done by electric with absolute certainty of securing power wherever needed. For commercial service, however, the distances need not be long, and it is maintained that practically 80 per cent. of the highway haulage is within the radius of movement of electric wagons.

The number of manufacturers of electric vehicles is increasing. There has been a very pronounced development of the industry, with reference to both pleasure and service machines. Several concerns now build both electric and gasoline wagons and there is general recognition of the fact that each type is adapted for specific work and each has a distinct field. The machines are designed with great care, constructed of the finest of material, and are from every viewpoint far more dependable and enduring than those which have given such remarkable service. The period of usefulness or service of an electric wagon is generally fixed at 10 years with reasonable maintenance and upkeep, but this can be regarded as decidedly conservative if systematic attention is given.

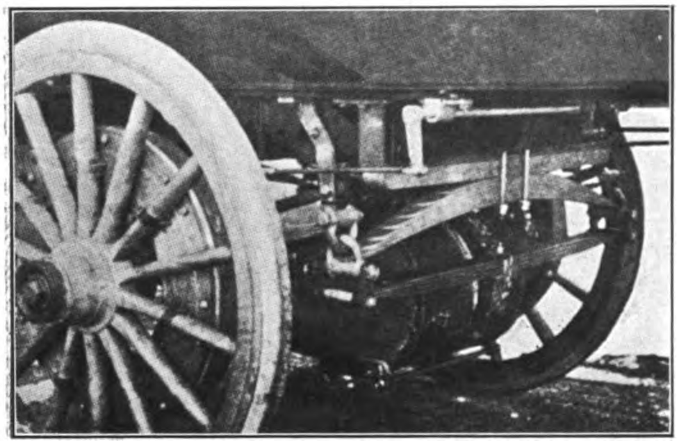
Five-Ton Vehicle Equipment Truck Purchased in 1903 by Stern Brothers, New York City, and Used in Transfer Service Between the Store in 23rd Street and Harlem, Making 40 Miles Each Working Day.

The owner of electric vehicles will usually find that the larger the number in use the greater the economy obtained, because the number of men required to properly care for them is comparatively small. In fact, a crew for a large garage is but a few men, and all these need not be expert, as there is considerable labor needed that does not entail mechanical knowledge or skill. The equipment for charging is not expensive and when once installed it should be serviceable for a period of years. The rate of insurance is low as compared with gasoline machines. Horse drivers who are familiar with the streets and localities and the traffic can be employed.

The public service station can be independent of or incorporated with the service of the central station. It may be a private enterprise or it may be a department, according to the desires of the management, and it may be conducted to a system that will insure the height of attention. The exclusive service wagon garage is certain to be as much of a business as the pleasure garage is today, and it is not impracticable for such a service to be conducted on a co-operative plan, in which each member or owner will receive a guaranteed quality of work and care.

There is, of course, a point where the owner of a delivery service will secure the greater economy by maintaining his own garage, but this will differ materially and is largely dependent upon conditions. It cannot be determined save with reference to each particular case and there is no rule that can be applied, for many factors must be considered. One of these is the rental, another is the cost of current, a third is the number of machines to be cared for, a fourth is the manner of use, a fifth is the character of attention desired, a sixth is the service with reference to battery

maintenance, a seventh is the labor, an eighth is the knowledge of the machines, a ninth is the stock of spares and material that should be carried, a tenth is



The Rear Construction of the First Columbia Heavy Delivery Wagons.

the garage equipment, and besides these there is the probable expansion to be considered.

The cost must be carefully estimated, and when this has been compared, with the garage charge for service and the other expense a reasonably definite conclusion can be arrived at. But it is apparent that there will be variance with each particular service and it is not possible to apply a rule that will serve equally well with all. Where the current may be bought cheaply as compared with other localities, there may be less, or even no reason to make energy, and where the requirement is very large it may be very profitable to do so. Where a power plant is operated current production is generally practical. In some instances it has been found economical to make energy with but one or two machines to charge.

A custom with many of the central stations is to sell current by a scale of prices, so that the large consumer pays less a kilowatt-hour than one using less, and it may be that such a system of charging would bring the cost very low for a garage of considerable proportions. Not only this, the continuance of the garage service must be considered rather than the monthly charge. Of course there are the maintenance and tire bills to be added to the public garage service cost, although there are garages that will make contract for maintenance and attention, but these are very infrequent.

It is not possible to estimate the labor required because of the varying capabilities of men who may be employed. A batteryman is needed in every garage of proportions, and he can be a very large economy if he is expert. The charging should be entrusted to a man who has been well trained and can determine conditions from his observations of the instruments. Occasionally a mechanic can be obtained who can care for the wagons and do the charging. In most garages of size the work is not combined, but it could be performed by one man to good advantage.

Reference is made to these factors because they are of much importance in any garage proposition. It is expected that the public station will have the service of men of sufficient experience and skill to do whatever work is necessary, and that the management will always have the machines ready for use when required unless it is impossible to do so.

(To Be Continued.)

CALIFORNIA OWNERS WIN.

Recently Organized Motor Truck Club in Los Angeles Secures Proper Consideration of Taxation Plan.

The Motor Truck Club at Los Angeles, Cal., which was recently organized, has already demonstrated its usefulness and value to motor truck owners, in having secured proper representation before the city council. The latter had prepared an ordinance requiring a local tax on commercial motor vehicles, based on the horsepower rating. A conference was held with the city attorney with the result that the ordinance was amended on the tonnage basis, as follows: Motor trucks of less than one ton capacity, $5 a year; one to two tons, $10; two to five, $20; more than five, $25.

An attempt is to be made to revive the proposed state registration bill, which failed to secure the approval of Gov. Johnson last year after having been passed in the legislature. Under the present regulations California owners are required to register their machines but once, the fee being $2. The new law would provide an annual fee, as follows: Less than 20 horsepower, $3; 20-30, $5; 30-40, $7.50; 40-50, $10; 50-60, $12.50; over 60, $15; motorcycles, $2; manufacturers and agents and dealers having the whole state

The First Baker Electric Runabout, in Which the Motor and Rear Axle Were Combined.

territory, $25; agents and dealers with less than entire state territory, $10. This schedule is claimed to be excessive, as it covers old and new machines alike.

TESTING CABLES WITH ELECTRIC TRUCKS.

Boston Edison Company's Equipment to Determine Condition of Power and Light Mains the Only Apparatus of the Kind—A Very Valuable Installation.

WHAT is an unusual use for motor trucks is made of two General Vehicle five-ton machines by the Edison Electric Illuminating Company of Boston, which has had constructed what is, so far as is known, the only portable cable testing apparatus in the world. The value of the equipment from a monetary point of view is large, and its use may seem comparatively limited, but that there is economy for a public service corporation of the proportions of the Boston company to utilize such method of test can be judged from the fact that the trucks were purchased and equipped after careful estimate of the expense and the possibilities.

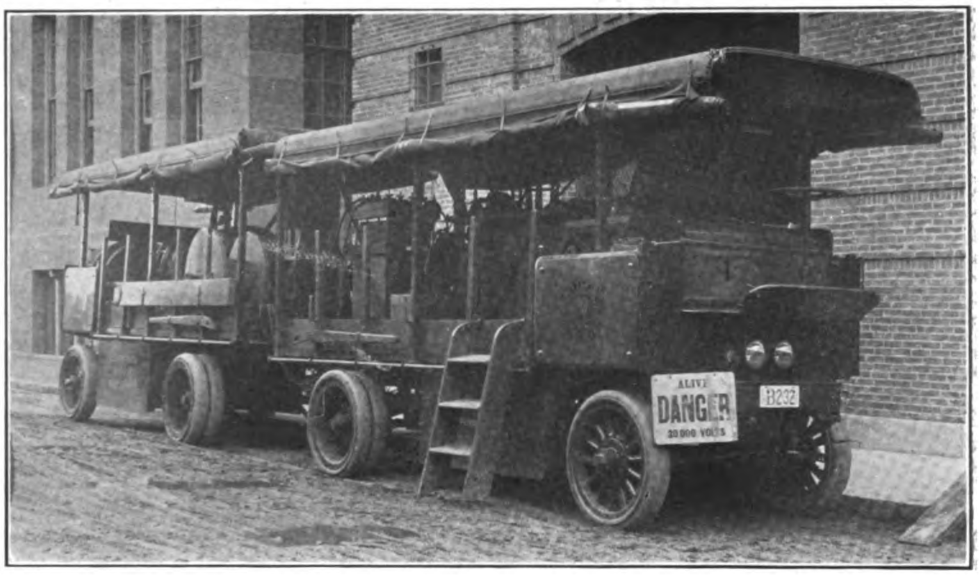
The area of the cities and towns served by the company is about 550 square miles and there are 38 different municipalities. In this section, which is about half the size of the state of Rhode Island, and has about three times the population of that state, the distribution of current is by cable mains. The construction is often in the form of conduits and in these the cables are stretched. There are manholes at frequent intervals that afford access to the cables and conduits. The demand for underground mains is increasing each year from the necessity of safeguarding the public and to avoid the possibilities of damage or destruction from severe storms. The protected cables cost more and the construction is regarded as being practically permanent, and to insure the greatest degree of permanency the new cables are tested carefully, while mains that are suspected of deterioration are also examined and tried to ascertain whether or not they are equal to the loads carried.

While tests were made prior to the building of the apparatus with a reasonable degree of certainty, it was believed it would be best to secure more definite determinations, and with this purpose in mind the company's engineering staff prepared the plans for a portable equipment. Technically it is known as a high potential cable testing set, and it is used by the laboratory department in testing the underground, lead encased mains. These cables are composed of varying series of copper wire imbedded in and protected by insulating material which is surrounded by the circular coating of lead.

When the cables are manufactured they are, if a single or a series of wires, first insulated, and the expectation is that this process is uniform. After the insulating they are passed through a machine that applies the lead coating or cover. The lead is expected to be a thorough protection against ordinary causes of deterioration, and they are expected to be impervious to influence of continued immersion in water. The cables are inspected, passed as perfect and delivered with a guarantee of specific capacity, which is the basis of the work required of them. That is, the cables are provided with a view of the requirements, and there is a cértain factor of safety allowed. There are, however, reasons why the cables may be subjected to overloads under certain conditions, and it is desired to test them to the capacities.

With this apparatus all kinds of underground lead cables, such as three-conductor high voltage transmission, single and three-conductor low voltage transmission and distribution, and arc circuit cables, are tested. With new cable the test is principally made to prove the manufacturers' guarantee, and with old cable the purpose is to determine its condition and prevent failures. The test consists of applying a voltage in excess of the normal operating voltage for a certain length of time, and if the cable endures the trial it is approved, but if the cable insulation is punctured it proves that it was defective—at least at the place of puncture.

The apparatus comprising the set is mounted permanently on two electric trucks, which are numbered 1 and 2, and which are rated at five and six tons, respectively. Truck No. 1 weighs complete approximately 21,000 pounds, and Truck No. 2 23,000 pounds. The machines are the General Vehicle five-ton chassis



Boston Edison Company's Portable Cable Testing Set, Mounted on Two Five-Ton General Vehicle Trucks, Ready for Service.

with extra heavy springs. While not in use the chassis frames are jacked to relieve the springs and prevent them taking a permanent set that would reduce their resiliency and efficiency. Were the springs not jacked it would be necessary to frequently replace them.

The trucks are intended to be driven about 30 miles on one battery charge and have a maximum speed of about 7.5 miles an hour. They are equipped with Edison A-12 60-cell batteries, which are divided into 12 crates of five cells each for convenience in handling. Each truck is fitted with a single five horsepower motor. There is one set of external band brake shoes on the rear wheels, but it is purposed to fit an additional set of brakes on the countershafts, and besides this the reverse may be used for retardation. Extra curtains have been provided for each machine to protect the electrical equipment from storms. Electric lights are fitted to the trucks and fire extinguishers are provided to meet any emergency. All of the electrical testing machines and apparatus are mounted on the decks of the platforms and are fully protected by the canopy and the curtains.

Truck No. 1, on Which Is Mounted the Transformer and Auxiliaries for Using a Current of 30,000 Volts Through a Cable.

The testing equipment installed on No. 1 truck is as follows: One 800 K. V. A. 2300-volt to 15,000/30,000 60-cycle, air-blast transformer; one 850 K. V. A. 60-cycle, air-blast portable reactance; two motor driven blower sets; one five K. W. transformer for blower motors; one 15,000-volt potential instrument transformer; one spark gap and resistance; one complete switchboard; one set of cable fault locating apparatus; one set of jumper cables, together with a complete galvanometer outfit, tools, jacks, rope and all other auxiliary apparatus.

On Truck No. 2 is installed one 100 K. W. motor-generator set, consisting of a 100 horsepower 60-cycle three-phase 2300/4000 induction motor, connected through a flexible coupling to a 100 K. W. 60-cycle 2300-volt three-phase synchronous generator having a two K. W. exciter mounted directly on its shaft; one starting compensator, one complete switchboard, one set of jumper cables, one set of portable motors and auxiliary equipment.

All of the electrical testing apparatus is so mounted mechanically that it will not become loosened or be damaged by the vibration of the truck as it is driven over the inequalities of the street and road surfaces. To accomplish this purpose it has been found necessary to strongly brace it and use washers and check nuts with all bolts. All of the exposed, important wiring is protected by metal conduits. The layout of the entire apparatus, and that of the switchboards, is such that a test can be quickly made, and the number of connections is minimized.

The manner of using the trucks in making a test is as follows: From the garage the trucks are driven to the location where the test is to be, where they are connected and the motors placed in circuit. Power is obtained by jumper cables from the nearest source of current, such as a sub-station, an overhead or an underground wire, but this power must be three-phase 60-cycle 2300 to 4000-volt, which is used to drive the 100 horsepower motor.

The generator driven by the motor produces a variable voltage from zero to 2300 volts, with 100 K. V. A. capacity at 2300 volts. This voltage is stepped-up or intensified by the 800 K. V. A. transformer to 30,000 volts, when the generator is giving 2300 volts. The 30,000 volts is impressed on the cable under test and all the necessary readings are taken. The reactance is connected in multiple with the 2300-volt side of the step-up transformer, and its function is to neutralize the leading current, due to the cable condenser action. The reactance is provided with a series of taps so that just the amount necessary can be connected at any specified test.

The apparatus has been used to make approximately 180 tests up to the present time and has proven to be decidedly successful for the purpose designed. During these tests much data has been obtained, both from the electrical cable and the vehicle service viewpoints. A log has been kept of the different works, from which data a series of curves have been plotted, these showing the ampere-hours used a mile, a work, and the number of miles driven a work or test.

The machines have been in service during the

greater part of the present year, and while they have not been driven a mileage that would be compared with machines used wholly for haulage, they have been given a very unusual test as they have been heavily loaded since the apparatus was installed upon them. They are probably the only two vehicles in service in the world that are never unloaded. Aside from jacking the frames to relieve the springs this also prevents maximum weight on the tires, which would undoubtedly be destructive of shoes.

ELECTRIC VEHICLE ASSOCIATION.

Plans Developing for Increasing Appropriation Providing for Dissemination of Information.

The headquarters of the Electric Vehicle Association of America are at 124 West 42nd street, New York City, which is the office of Secretary Harvey Robinson, and here on the fourth Tuesday of each month is held a meeting of the board of directors, at which time the business affairs are considered. The monthly meetings of the association for members are held at stated places the evening of the same day, when subjects of general interest are discussed and decided.

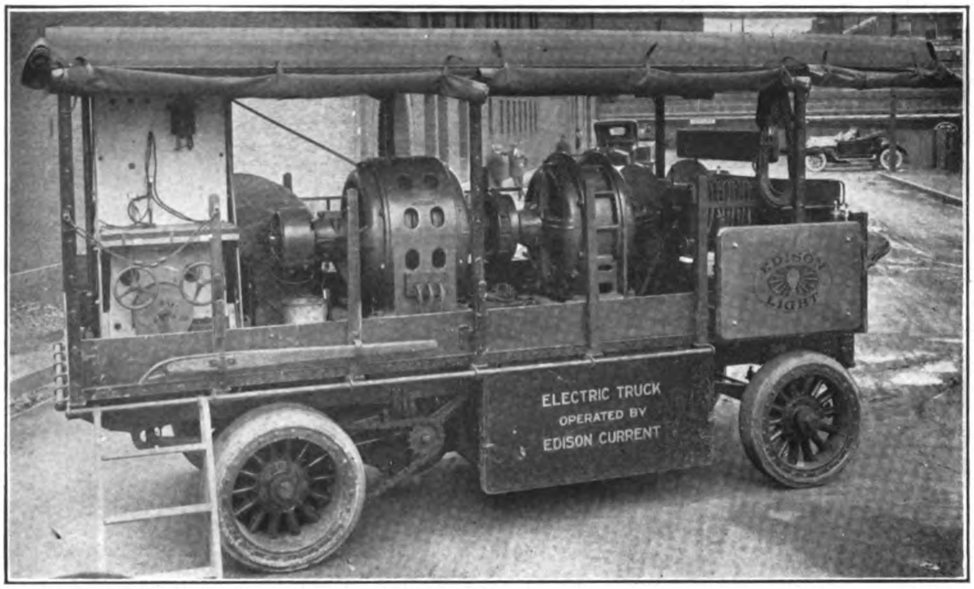
It is the intention of the association to devote more careful attention to publicity the present year, and the subject of advertising will be taken up systematically, probably under the direction of the publicity and advertising committee.

At the convention in Boston in October a number of subjects were given presentation that were deserving of more studied inquiry, and as the discussion at that time has been published, these printed reports are to be systematically debated with a view of developing opinions. Many valuable suggestions were made and it is purposed that these be taken up in connection with the monthly meetings and the ideas crystallized so far as this may be done. That the members may have the fullest information on the subjects copies of the printed reports have been mailed to them.

As an example of the value of these meetings may be stated that at which President Arthur Williams presided for the first time. One paper read at the Boston convention stated that there was a saving of $400 a year by the use of a 1000-pound electric wagon in the place of a horse vehicle, and $1100 a year by the use of a five-ton electric in the place of a horse equipment capable of doing the same work. After very carefully going into the subject it was decided that these figures were conservative and could be safely stated as an average.

The association has as a whole approved the campaign of publicity that was inaugurated more than a year ago, and so confident are the members of the value of systematically advertising the economy of the electric vehicle that the sentiment appears to be favorable to the expenditure of $100,000 for this form of promotion during the present year. The first year's expense for advertising was somewhat in excess of $40,000, and with the experience gained it was believed that the association would be justified in expending $100,000, which amount was recommended by the committee on advertising and publicity. This committee is now raising the fund for advertising and with a view of securing the amount stated.

The standard garage sign of the association is to be conspicuously placed in one or more locations in main thoroughfares of all communities where a garage



Truck No. 2, Which Carries the Motor-Generator and Equipment for Generating the Energy Supplied to the Transformer.

exists that has vehicle charging facilities. The sign is 48 inches length and 30 inches depth and has a background of blue, on which in large white letters is "Electric Vehicle Charging," and the emblem of the organization. The desire is to have these signs direct attention to garages that can afford satisfactory service.

The December meeting of the association was held the evening of the 17th, a week earlier than usual, for the regular night would have been Christmas Eve, at the Engineering Societies' Building, 29 West 39th street, New York City. The principal paper was on the subject of "The Central Station Influence on the Electric Vehicle Industry," and was prepared by S. G. Thompson of the Public Service Electric Company, Newark, N. J.

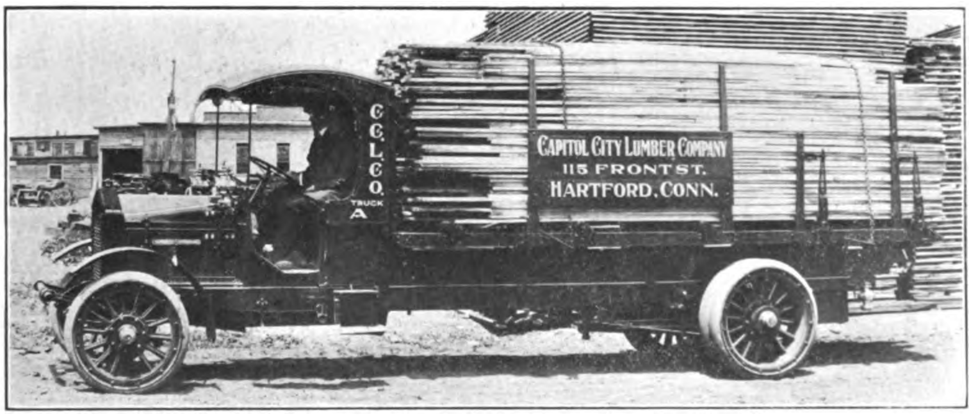
Benjamin Briscoe has resigned as director and secretary of the Automobile Board of Trade. John N. Willys becomes a director and Roy D. Chapin secretary.

PIERCE-ARROW TRUCK EQUAL TO 11 HORSES.

THE Capitol City Lumber Company, Hartford, Conn., a concern with an extensive business in that city and its suburbs, has had a Pierce-Arrow five-ton truck in its service since shortly before the first of September, and has realized a surprising degree of economy from its use. While the experience with the machine has been comparatively brief the company has been exceedingly careful to obtain information that is dependable and is keeping accurate record of the work accomplished and the cost.

When the machine was purchased a system of accounting for its service and the expense was devised, and an estimate made of the probable cost, considering every item of overhead or fixed charges. As against this the company has a very good knowledge of delivery by horses and the approximate expenditure for this department for years. The truck was purchased with a platform body with rollers installed in the deck to facilitate the handling of loads.

A four-wheeled wagon was fitted for loading the truck. This wagon is kept at the yard and when an order is received that will be delivered by the machine it is selected and packed on the wagon, which is then hauled to a convenient place in the yard. When the truck is in the yard it is backed to one end of the wagon and the load is transferred with comparatively little effort, the average time being about three minutes. The machine is then hustled away and it is unloaded in an average of about two minutes.



Pierce-Arrow Truck That Takes the Place of 5.5 Two-Horse Teams in the Service of the Capitol City Lumber Company, Hartford, Conn.

The truck will carry 5000 feet of dressed lumber as a load against 2500 feet for a two-horse team and wagon, and will make an average of 8.5 trips of five miles each, daily, covering 42.5 miles, while the animal outfit will make but three trips of five miles each, a total of 15 miles. The deduction is that the truck takes the place of 5.5 two-horse teams, and it is estimated that it will deliver lumber at 36 cents a 1000 feet as against a cost of 75 cents by two-horse team delivery. No statement is made as to the number of men the crew replaces, but the conclusion is that the same number attend the truck that would attend a regular horse outfit. The following figures are based on total investment, overhead, insurance, upkeep, repairs, operation, etc., with reference to both the truck and to a horse equipment unit:

	Pierce-Arrow Truck	Two-Horse Team
Total investment—with equipment	$5362.12	$1510.00
Total daily expense	15.26	5.63
Average daily mileage	42.5	15
Average round trip haul, miles	5	5
Average number trips a day	8.5	3
Average load, dressed lumber, feet	5000	2500
Average weight of load, tons	5	2.5
Total of loads carried daily, feet	42,500	7500
Total expense a 1000 feet, cents	36	75

AN ELASTIC SYSTEM.

Philadelphia Chemical Company Reaping All Advantages Claimed for Motor Truck Service.

The Baugh & Sons Company, manufacturing chemist of Philadelphia, has been operating five Peerless trucks, made by the Peerless Motor Car Company, Cleveland, O., and reports that the conditions surrounding its transportation problem have been such that it has profited by practically every advantage that is claimed for motor truck service. Four of the trucks are of three tons capacity and are used to collect raw material about the city and to deliver it at the Baugh plant. The fifth truck, which carries five tons, is used to transport the completed product from the plant to the various railroad stations and to the wharves.

The four three-ton trucks cover a wider territory than the teams they displaced. They make quicker trips and as the materials they handle deteriorate rapidly they deliver them at the plant in better condition and materially increase their value. Snow, slush and slippery hills, which are dangerous to horses, have given them no trouble. Very hot weather does not decrease the efficiency of the service. As the trucks can work overtime when necessary the system is elastic and a saving is effected in every branch of the work.

J. G. Brown, manager of a large brewery in Roxbury, Mass., states that the Packard trucks recently purchased by his concern have demonstrated their efficiency over horses beyond comparison. The company purchased the trucks on Sept. 24, Oct. 24 and Oct. 26, respectively, and no horses are now maintained. Two three-ton trucks take care of the barrel deliveries and one two-ton vehicle handles successfully the bottled goods trade. It is needless to say that the entire equipment has proven highly satisfactory.

Municipal Service Equipment

SOME NEW KNOX VEHICLES.

Massachusetts Cities Well Satisfied with Economy and Efficiency of This Equipment.

The Knox Automobile Company, Springfield, Mass., has delivered two more Knox cars to the city officials of Lynn, Mass., these consisting of a model M-3 combination hose and chemical wagon and a model R-64 combination patrol and ambulance. Both machines were driven over road from the factory and received much favorable comment from public authorities on the way. Lynn already has one Knox patrol and a Knox combination fire wagon of similar type, and the repeat order was decidedly gratifying to the Knox company.

Another new fire wagon of this make was delivered recently in Wakefield, Mass., and very soon after its acceptance it was called out on an alarm from the residential section. It was at the scene of the blaze within three minutes of the time the bell began sounding. The house was fully 1800 feet from a hydrant and this vehicle, which is of the triple combination type, was at work pumping water so soon as the hydrant was connected. The town officials were especially well pleased with the performance and expressed themselves as abundantly convinced of the efficiency of this particular apparatus.

In response to the desire of the fire engineers in Gardner, Mass., to test the Knox Martin tractor in what was regarded as severe work for a machine of this character, the company recently drove one of these vehicles to that town. The engineers were confident the tractor could not haul their steam engine up the steep hills in that section, but after taking the hook and ladder apparatus up the incline the steamer was handled in the same expeditious manner. As a result the town expects to purchase a tractor.

ECONOMY IN SPOKANE DEPARTMENT.

Careful Records for Nine Months Demonstrate Increased Efficiency with Motor Apparatus.

Commissioner Hayden of the fire department of Spokane, Wash., has concluded, from records kept by the department in that city, that motor driven fire apparatus can respond to twice as many fires, travel farther and carry more weight at less than quarter of the upkeep expense of horse drawn apparatus. It will be seen by a comparative record kept by Commissioner Hayden of two hose wagons of the Spokane department, that the motor apparatus travelled 49.72 miles more than did the horse drawn vehicle, while answering 86 more alarms. And this increased mileage and efficiency was accomplished at a cost of $234.43 less than was registered for the maintenance of the horse drawn drawn apparatus. The record follows:

Knox Patrol Wagon and Combination Hose and Chemical Engine, Comprising a Repeat Order from the City of Lynn, Mass.

Hose Wagon No. 9, Horse Drawn.
(Report for Jan. 1-Sept. 30, 1912).

Shoeing horses	$71.90
Forage	214.40
Repairs	.60
General supplies	19.60
Total	$306.50

Total alarms answered, 73.
Miles travelled, 148.78.

Hose Wagon No. 5, Motor Driven.
(Report for same period.)

Oils and gasoline	$29.67
Repairs	20.03
General supplies	22.37
Total	$72.07

Total alarms answered, 139.
Total miles travelled, 198.5.

DETROIT'S MOTOR EQUIPMENT.

Head of Fire Department Has Proceeded Cautiously but Now Is Well Supplied with Automobiles.

Proceeding cautiously during the first stages of the development in automobile fire apparatus, Detroit, Mich., now boasts of a motorized fire department as well equipped as most cities of its size in the country. Chief Broderick carefully studied the problem and did not invest until he felt sure that the machines he purchased would not be declared obsolete in a few months and would have to be discarded.

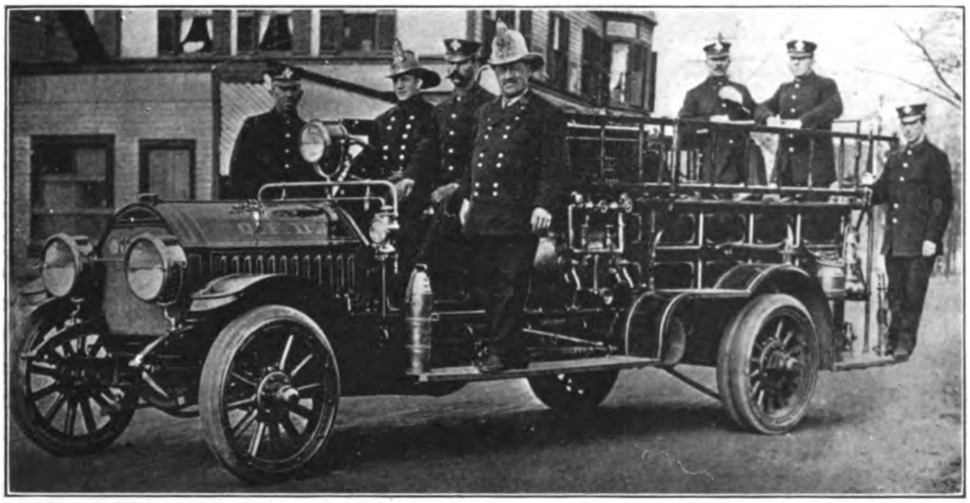
Detroit was one of the first cities to install a flying squadron. Now there are two high powered cars, each carrying a dozen men whose duty it is to respond to all calls in their district and join with others of the department in handling the apparatus. It is not long since the first motor pumping engine went into service and now five of these have taken the place of as many steam engines and others will soon be added. Two ladder trucks have been motorized with more to follow in due season, and Chief Broderick and each of the six battalion chiefs answer alarms in automobiles provided for their official use. It is only a question of time before horses will be unknown in the Detroit fire department.

"The death knell of the horse has been sounded, much as some of us who have been with the department so long may regret, from purely sentimental reasons," says Chief Broderick. "Motor driven apparatus is not an unqualified success in every respect as yet. It will come eventually, but while this changing over is taking place and improvements are so frequent it is just as well to proceed cautiously. We are adding motor apparatus at a pretty good rate, but we want to make sure as we go along that it is the best obtainable."

KISSELKARS IN QUINCY, MASS.

Two Pieces Added to Fire Department's Equipment After Satisfactory Test of Original Purchase.

The fire department in Quincy, Mass., has just added to its equipment a new KisselKar combination wagon and a KisselKar chief's car, made by the Kissel Motor Car Company, Hartford, Wis. The chief's car was formerly a touring car used for demonstration purposes by the Kissel company. The rear seat was displaced by a 25-gallon chemical tank. The tank is the same as used for big combination wagons and carries 150 feet of small hose. The machine also is equipped with an axe and crowbar. The new combination wagon is larger than the first one installed by the city and carries two chemical tanks, 200 feet of small hose, 1000 feet of large hose, second-story and roof ladders, axes, crowbars and other appliances. The engines are six-cylinder and of 60 horsepower. On a recent test, fully equipped and carrying in addition 21 men, the machine climbed the steepest hills in the city with apparent ease.



KisselKar Combination Fire Wagon Recently Placed in Service in Quincy, Mass.

GENERAL NEWS FROM OTHER CITIES.

Seeking to Convert Steamers—The motor fire apparatus at Baltimore, Md., has been such a success that the fire board has decided to ask the board of estimates to grant an appropriation to convert at least four of the engines into automobile steamers. It is also planned to replace the horse drawn vehicles used by the district chiefs with motor wagons similar to those used by the chief and deputy chief.

Recommends Motor Apparatus—The National Board of Fire Underwriters has filed a report of a recent inspection of the fire-fighting facilities in Indianapolis, Ind. The board recommends that all new apparatus bought for the department and all apparatus of companies making long runs on the first alarm shall be motor vehicles.

Pope-Hartford for Fairhaven—Fairhaven, Mass., has received from the factory of the Pope Manufacturing Company, Hartford, Conn., a new Pope-Hartford motor chemical wagon. The vehicle is double tanked and is larger than any of those located in the city of New Bedford, Mass., which is near Fairhaven. It is an unusually attractive car, with ladders well inside the line of the wheels. The truck has double chain drive, and has a chemical tank of 35-40 gallon capacity. It has three compartments carrying 600 feet of hose on each side, 250 feet of chemical hose, four chemical extinguishers and two Pyrene extinguishers. The ladder equipment comprises a 35-foot triple extension and 12-foot inside pole ladder, which collapses for handy carrying. The machine has a wheelbase of 148 inches and carries 12 men.

Quick Long Distance Run—The value of motor fire apparatus was recently demonstrated at a fire in Essex Junction, Vt., when Johnson's hotel was destroyed with a loss of $25,000. That this was not greater was due to the quick response to a call for outside aid by the motor fire truck from Burlington, Vt. The vehicle with its crew made the run of seven miles to Essex Junction in eight minutes. This was considered all the more remarkable in view of the fact that it was made at night. Immediately after the arrival of the Burlington firemen with the modern apparatus, the fire was placed under control and its spread prevented.

To Install Electric Pumping System—Going even a step beyond the aims of most cities that are seeking to introduce automobile fire fighting apparatus on a large scale, municipal authorities at Cleveland, O., are at work on a plan to adopt an electric pumping system, patterned somewhat after that employed in the city of Berlin, Germany. With the co-operation of the city lighting system, electrical connecting plugs will be established beside the water plugs, so that current for operating the pumps may be obtained directly. The pumps will be mounted on automobile chassis and manufacturers estimate that equipment to pump 1000 gallons a minute will weigh about three tons each and cost in the neighborhood of $2000.

White Truck with Interchangeable Bodies—The overseers of the poor of Worcester, Mass., have purchased a 30 horsepower, three-ton, gasoline driven motor truck chassis of the White Company, Cleveland, O., to which two or three changeable bodies will be fitted. The machine will be used to haul supplies, such as coal, hay, grain and other commodities, to the home farm, for carting away live stock and many other uses. It is the intention of the overseers to experiment with the new truck in making special garbage collection trips from markets, hotels and other places, and it is expected that the first season there will be saved the first cost of $600 for a pair of draft horses and their maintenance.

New Orleans Adds Two Pieces—The city of New Orleans has installed a new automobile aerial truck and two runabouts to be used by assistant chiefs of the fire department. The runabouts have a capacity of 30 horsepower and were made by the Buick Motor Company, Flint, Mich. The reconstructed aerial truck is of 80 horsepower and has an 85-foot ladder. The apparatus will respond to alarms in the business section of the city. It was constructed by the Seagrave Company, Columbus, O.

South Manchester Buys a White—The White Company, Cleveland, O., has made delivery of a motor hose wagon to the fire department of South Manchester, Conn., and it is now in active service. It has the 1500-pound chassis such as is used on the White trucks and is equipped with two chemical extinguishers, two nozzle stands, two nozzles, chemical and fire hose, extra ladders, etc. The engine is rated at 30 horsepower and among the features more peculiar to a fire automobile are electric ignition for the gas lamps, United States non-skid chain tires and automatic air pump.

In the Market—Following are some of the cities that are in the market to purchase motor driven fire apparatus: Lebanon, Penn.; San Jose, Cal.; Orange, Mass.; Providence, R. I.; Venise, Cal.; Woburn, Mass.; Milbury, Mass.; Melrose, Mass.; Beverly, Mass.; Waycross, Ga.; Cedar Rapids, Ia.; Lockport, N. Y.; Sidney, O.; Garden City, Kan.; Beaver, Penn.; Hopkinton, Mass.; Kingston, N. Y.; Halesite, N. Y.; Roselle, N. J.; Swampscott, Mass.; Chatham, N. J.; Bayonne City, N. J.; Aberdeen, S. D.; Farrell, Penn.; Sioux Falls, S. D.; Palestine, Tex.; Harrisburg, Penn.; Sherman, Tex.; Knoxville, Tenn.; Hallettsville, Tex.; Amsterdam, N. Y.; Springfield, Mo.; Englewood, N. J.; Joplin, Mo.; Haverhill, Mass.; Pueblo, Col.; Utica, N. Y.; Goliad, Tex.; Billings, Mont.

Recent American-La France Deliveries—The American-La France Fire Engine Company, Elmira, N. Y., maker of motor fire apparatus, recently made deliveries of motor propelled vehicles to the following cities: Hot Springs, Ark.; Houston, Tex.; Fort Worth, Tex.; Memphis, Tenn.; Shreveport, La.; Zanesville, O.; Tuckahoe, N. Y.; Ocean Grove, N. J.; Elizabeth, N. J. The following orders for apparatus have been received: Astoria, Ore.; Pueblo, Col.; Palatka, Fla.; Tarboro, N. C.; Decatur, Ala.; Dayton, O.; Raleigh, N. C.; Warren, Penn.; Boston, Mass.; Greenwood, Miss.; Beverly, Mass.; Point Grey, B. C.; Salisbury, S. C.; Duluth, Minn.; Quitman, Ga.; Vancouver, B. C.; Halifax, N. S.; El Paso, Tex.; Somerville, Mass.; Danville, Va.; Danbury, Conn.; Atlanta, Ga.; Winston, N. C.; Belmont, Mass.; St. Petersburg, Fla.; Park City, Tenn.; Richwood, O.; South Bend, Ind.; San Antonio, Tex.; San Francisco, Cal.; Boston, Mass.; Manchester, N. H.; Richmond, Va.; Yonkers, N. Y.; Manila, P. I.; Pittsfield, Mass.

PUBLISHED THE FIRST OF EACH MONTH.

SUBSCRIPTIONS:
The United States and Mexico, the year, $1 in advance; Canada and Foreign Countries in Postal Union, the year, $2 in advance. Fifteen cents the copy.

ADVERTISING RATES.
Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.
Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.
Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

THE BUYER AT THE TRUCK SHOW.

The value of the display of service vehicles to the man making a study of transportation problems and machines is in the opportunity it affords him to make comparisons of types that will serve his purposes. The man who proposes to make investment of a considerable amount of money generally desires to learn what he can of machines he believes worthy of consideration, and while it is not probable he will make decision without careful reflection he will undoubtedly avail himself of every opportunity to secure information that will benefit him.

The man who is investigating the use of motor wagons may have specific uses in mind, but what he wants to know is whether the machine of which he is inquiring will meet these needs. All the mechanical descriptions ever conceived will not supply this information, although interestingly told. Work accomplished and the experience of those who have used such machines in similar haulage or transportation are facts that will interest the visitor. Some practical expense statements and facts relative to care and maintenance are worth presentation, because they have the merit of actual service and are not theories or suppositions.

The business man judges from his own estimate of value and he is more inclined to accept conservative statements, or the results found by those who have used vehicles, than to be convinced by rehearsal of instances that at best may be demonstrations made by experts, who have intimate knowledge of the machine and who have every reason to make the greatest showing possible.

CONTROL OF SERVICE WAGONS.

The increase in the number of accidents resulting from the use of service wagons, especially that class where the victims are careless or regardless of the probable dangers, emphasizes that too great care cannot be given by designers to perfecting the methods of control. By this is meant that the brakes should be extremely powerful and sufficient to stop a machine in a very short distance. The statement is not a reflection upon existing vehicles or designs, but with traffic increasing in the streets and the pedestrians rapidly multiplying in numbers, the protection of the public and the owners and operators of vehicles is imperative.

The carelessness of the people is well known and despite the greatest care by the drivers it is impossible to avoid accidents, but with brakes that will make certain that a machine can be stopped in a very few feet there will be a greater degree of protection than now exists. It is not merely a question of holding a vehicle and its load on a grade, or stopping in a given distance, but it is a proposal to stop a machine against its momentum at maximum speed in the briefest time as a safeguard against accident or fatality. Accidents may be excusable, but it is far better to have construction that will minimize them, if not prevent them.

THE PROBLEM OF TRUCK TIRES.

The cost of service vehicle tires is regarded by practically every owner and user of a motor wagon as being the largest item of expense and the most important problem to be dealt with. The experience of those using pneumatic shoes is that the larger sizes wear longer and give the best service, to say nothing of the greater comfort and the lessened vehicle repair bills. The experience of English service wagon owners is that with large tires the greatest economy is obtained. The British makers equip their vehicles with larger sizes as a rule than do American builders. This leads to the supposition that it might be more economical to use larger tires than are now regarded as sufficient for the load carried in this country. This would necessarily increase the initial cost, but it might be an expense that would be justified by results, both as regards tires and vehicle maintenance.

SOLVING THE SUBURBAN DELIVERY PROBLEM.

Furniture House in Louisville, Ky., Finds Its Answer in Mais Truck—No Comparison Possible in Matter of Efficiency—Figures Show Undoubted Economy.

By G. D. Crain, Jr.

ECONOMY is the argument to which chief attention is paid in presenting the merits of the motor truck for the consideration of the prospective user. In a measure, this is the result of a desire on the part of the business man to learn whether he can save money by installing power driven vehicles instead of continuing to use his horse drawn equipment. And stress likewise is laid on the ability of the mechanical transport to accomplish a certain amount of work which cannot be done with the older type of delivery.

There are instances, however, in which the introduction of the modern method of haulage has not been due to a consideration of either economy or efficiency, but to the fact it is capable of providing service which was utterly out of the question under the old system. Inasmuch as such use of the truck is largely dependent upon initiating work that was never attempted before, this feature is of prime importance.

It should be remembered that inertia is a decided factor in the prevention of sales, and that where a merchant or manufacturer has a complete equipment of horse drawn apparatus from which he is obtaining fair satisfaction even though it can be shown that it is more expensive than the mechanical transport would be, he hesitates to make the investment necessitated by the change. But when it becomes possible to show him that the truck offers him something he can get in no other manner, the effort is much easier.

For the purpose of illustration, the furniture business may be selected. In this line, especially in some of the cities outside of the larger metropolitan centres, the business done with the people of the outlying sections and in the important farming communities immediately adjacent thereto is sufficient in the aggregate to become an item worthy of decided consideration.

The delivery problem has been one of the chief troubles of the furniture dealer. Getting the purchase from the store to the distant customer is a proposition that under the usual system of horse drawn equipment involves crating the goods at the store, hauling them to the depot, shipping by rail to the station nearest the purchaser, and then arranging for the completion of the haul to his home.

To begin with this system is slow and expensive. In addition, it is unsatisfactory to the customer because of the inconvenience of having to make the final delivery, and because the furniture frequently is damaged in transit. There seemed to be no way out of the difficulty, however, until the motor truck was given a trial, and it fully met expectations.

To cite a specific instance, reference may be had to the Denhard Company of Louisville, Ky., one of the largest retail furniture concerns in the Ohio valley and

Mais 3000-Pound Truck in Furniture Delivery Service with the Denhard Company, Louisville, Ky.

one of the most successful operators of the mechanical transport in making long distance deliveries of the nature indicated. The experience of this concern has been such as to demonstrate that not only is it possible to solve this problem in an efficient and economical manner, but to attract and retain custom that could be obtained in no other way.

Louisville is in the heart of a rich agricultural district, and the business of the Denhard Company extends over a radius of 30 miles in all directions. It had developed this market until it had reached proportions almost as important as the purely local business with the residents of the city itself, when it became evident that this suburban trade, while satisfactory in all other respects, was far from being so in connection with the

DENHARD COMPANY'S COMPARATIVE FIGURES.

Monthly Cost of Two-Horse Team.

Feed	$30.00
Shoeing	4.00
Repairs	3.00
Driver	65.00
Helper	40.00
Total for one team	$142.00
Total for three teams	$426.00

Monthly Cost of Mais Truck.

Gasoline	$16.90
Oil	4.00
Grease	1.50
Tires and overhaul	20.00
Driver	78.00
Helper	40.00
Total for truck	$160.40
Balance in favor of truck	$265.60

delivery of goods. Customers were irritated by the long delays involved when the furniture was handled by the railroads, and this feeling was intensified when the merchandise arrived, as it did sometimes, in bad condition.

To meet this situation and to make a direct-to-you proposition, the company finally decided to install a motor truck. In this action it adopted an entirely new policy, since it not only intended to use the vehicle for the work which its horses and wagons had been doing, but to substitute it for railway transportation. Although entering upon a situation possessed of all the uncertainties which attend any pioneer undertaking, the officials of the company had the courage of their convictions, and happily have found every expectation in that direction fully realized.

The vehicle purchased was a 3000-pound Mais, made by the Mais Motor Truck Company, Indianapolis, Ind., fitted with a 24 horsepower, four-cylinder engine, at a cost of $3200. This has been used in both local and country deliveries, and in the latter connection frequently has hauled furniture as far away from the store as 40 miles. Officers of the company are extremely enthusiastic as to the results which have been obtained.

"It has replaced three teams and wagons, to put it at a very low estimate," states one of the officials. "That is, we had five double teams and wagons, and the truck has displaced three of them. And this is taking no account of the increase in our business in the meantime, nor of the fact that this truck has been hauling our freight for us, a work which formerly was done by an outside concern under contract. That, by the way, is an item worth noting. We formerly paid this freight hauling firm anywhere from $60 to $150 a month. Now this truck handles the work without any trouble and takes care of its regular deliveries at the same time. In point of efficiency and economy there is simply no comparison between the wagons and teams and the truck.

"Then there is its advertising value, which also is worth considering. It is pretty nice to be able to tell people that we can deliver to them at towns 30 and 40 miles away—lay the furniture right down in their homes, instead of having to crate it, haul it to the station, prepay freight, take the risk of breakage en route, and then tell the customer to go to the station when the goods finally arrive and haul them home himself. I am not saying it is an actual saving in point of money laid out, because I hardly think it is, but there is no comparison in the value of the service rendered, and of course that means more business.

"The people out in the little towns and in the country like to have the truck come to the house, too. It gives them a sense of importance, the gratification of which is an appreciable factor in bringing them to our store for their furniture. And this feeling isn't confined to the country, either. I have had people right here in town give us an order for a bill of goods on the express condition that we send the stuff out on the motor truck.

"For emergency service, as where the customer wants a large order, the truck again is in a class by itself. It will carry twice as much as a two-horse team can pull, and do it more easily. We can load it up as soon as the order is given, unless it happens to be out on a long trip, and have the stuff on its way almost before the customer can get home. And he appreciates that sort of service, of course."

The actual figures justify the company's enthusiasm concerning the mechanical transport—not this particular vehicle, necessarily, as the officer in question is careful to explain, but of any motor truck as compared with teams and wagons. A tabulated comparison of the cost of this 3000-pound Mais and the horse equipment it has replaced is presented elsewhere and shows a monthly saving of $265.60 in the delivery work alone, leaving out of the accounting the sum formerly paid for freight haulage—$60 to $150 a month. These figures need some explanation.

Gasoline is purchased under contract and costs about 13 cents a gallon. A gallon will run the machine nine miles, and its daily mileage, limited by a governor to a speed of 15 miles an hour, is about 40-45. Light oil, purchased by the barrel, costs approximately 40 cents a gallon, and about 10 gallons a month are required. Grease and heavy oil cost about $1.50 a month. The man who drives the machine gets $18 a week, as against $15 for the horse driver.

The set of tires with which the machine was originally equipped is guaranteed for 10,000 miles, and an entire new set costs $250. Based on the mileage above

ESTIMATE BASED ON DENHARD FIGURES.

Annual Cost of Three Teams.

Feed	$1095.00
Shoeing	144.00
Repairs	108.00
Drivers	2340.00
Helpers	1560.00
Depreciation	600.00
Interest	150.00
Total with horses	$5997.00

Annual Cost of Mais Truck.

Gasoline	$202.80
Oil	48.00
Grease	18.00
Tires and overhaul	240.00
Driver	936.00
Helper	520.00
Depreciation	640.00
Interest	160.00
Total with truck	$2764.80
Balance in favor of truck	$3232.20

stated, the tire cost is figured at about $10 a month. This depends upon whether or not the original set will outlive its guarantee period, and present indications are that, as a matter of fact, they probably will far exceed that mileage.

The company allows an estimated depreciation of $10 a month, but this does not represent its estimate of the difference between the price of a new car and that at which this machine would sell after being in use. If this figure be interpreted as in the nature of an allowance for repairs or an annual overhaul, it may be permitted to stand as such, but it must be assumed that the life of no truck can be adequately represented by an annual depreciation of 4 per cent. Most concerns place their estimate at 20 per cent. or over, figuring the life of the truck as five years, for instance, and considering anything beyond that as clear gain.

It will be conceded that the items for depreciation and interest are somewhat arbitrary in character, and this applies alike to the horse and motor equipment. Hardly any two concerns will agree as to the proper percentage to use with the former, and it is possible to find almost as much difference of opinion with reference to interest. If it be desired to eliminate these entirely from the discussion, let it be assumed that the three teams and the truck represent about the same investment, on which the same interest and depreciation may be figured, and that these items will balance. Certainly this will hold true if the freight charge be added to the horse figures, and it will be noted that the tables contain no reference to the cost of crating furniture to be shipped by railroad, which also has been eliminated by the use of the truck.

The two tables herewith merely set forth the situation from two slightly differing viewpoints. One contains the figures as submitted by the Denhard Company with the substitution of the word "overhaul" for "depreciation," and the other, that giving the annual cost, is based on these figures with an estimate of 20 per cent. for depreciation on both truck and horses and an interest charge of 5 per cent. on the estimated investment.

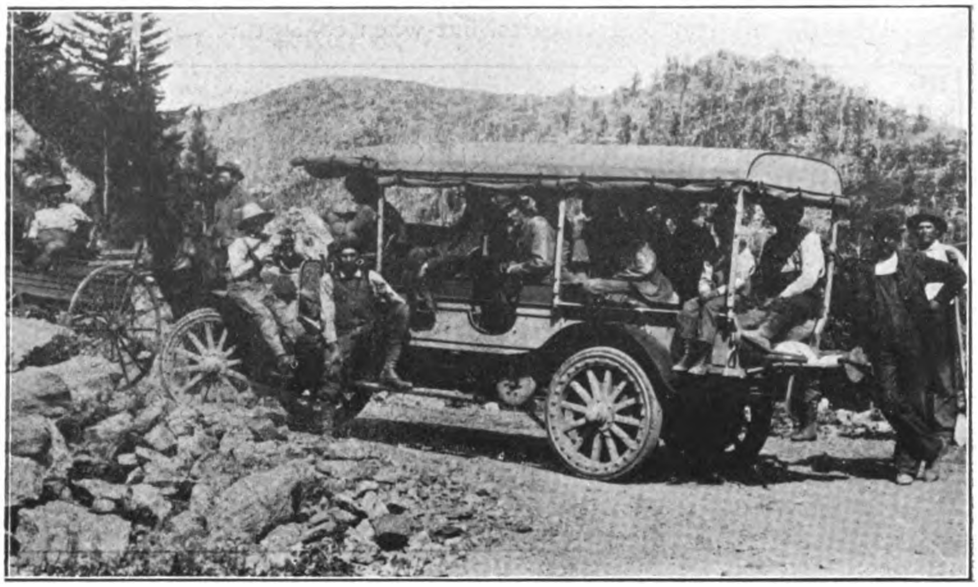
The Denhard figures show a monthly saving of $265.60, without including the freight haulage and crating. This would give an annual balance of $3187.20 —almost enough to purchase a new truck. The other table gives a slightly different result, the double teams with their wagons and harnesses being estimated at $1000 each, so as to bring their total value approximately that of the truck. If it be assumed that horses and wagons can be purchased for less money, the showing cannot be such as to effect the economy represented by the motor vehicle in any marked degree.

So well pleased is the Denhard company that within a short time it expects to replace the other two teams with a lighter truck, which will divide some of the work now being done by this vehicle and will make it easier for both. The plan is to allow the larger machine to do the long hauling and keep the lighter one for the city deliveries. "We cannot afford to use teams on the showing made by this truck," is the manner in which the company sums up the situation.

FEDERAL UNDERTAKES SEVERE TASK.

Operates as Motor Stage and Mail Wagon Over Winding Road at High Altitude.

A few months ago J. W. West of Idaho Springs, Col., purchased a one-ton Federal truck from W. W. Barnett, Denver agent for the Federal Motor Truck Company, Detroit. It was put into service as a motor stage and mail wagon, running from Idaho Springs to Alice, a distance of 11 miles. During the first three months of service it had not cost the owner one cent for repairs.



One-Ton Federal Truck Employed by J. W. West in Operating a Motor Stage Line Between Idaho and Alice, Col.

Some idea of the grades the vehicle is called upon to negotiate may be gained from the fact that the gradometer registers a pitch of 20 to 25 per cent. in places. The road twists and turns over a very rough course that formerly was used only as a trail. The car makes two trips a day, carrying mostly miners to the silver mines in that region.

The chassis is a regulation model D Federal, and is equipped with a combination body, having three cross seats which will accommodate nine passengers, and about four square feet of space in the rear for baggage and mail. Mr. West declares that although other dealers in Denver did not care to undertake the installation, the Federal has never missed a trip.

SUGGESTIONS FOR STARTING COLD MOTORS.

OPERATORS of commercial vehicles whose experience with the internal combustion engine has been limited to driving in warm weather, are encountering the same trouble in starting as drivers of the pleasure automobile. While difficulty was met last winter, there is even more this year owing to the heavier grade of fuel that is being marketed.

For the benefit of those not familiar with the principles involved in carburetion it is explained that the carburetor combines a certain amount of vapor with air and that the combination is termed the mixture. This is burned or exploded and the rapidity of the explosion depends largely upon the proper proportions of vapor and air. Briefly stated, a mixture having too much air is termed lean and burns slowly, while one heavily impregnated with vapor is said to be rich and tends to ignite more quickly.

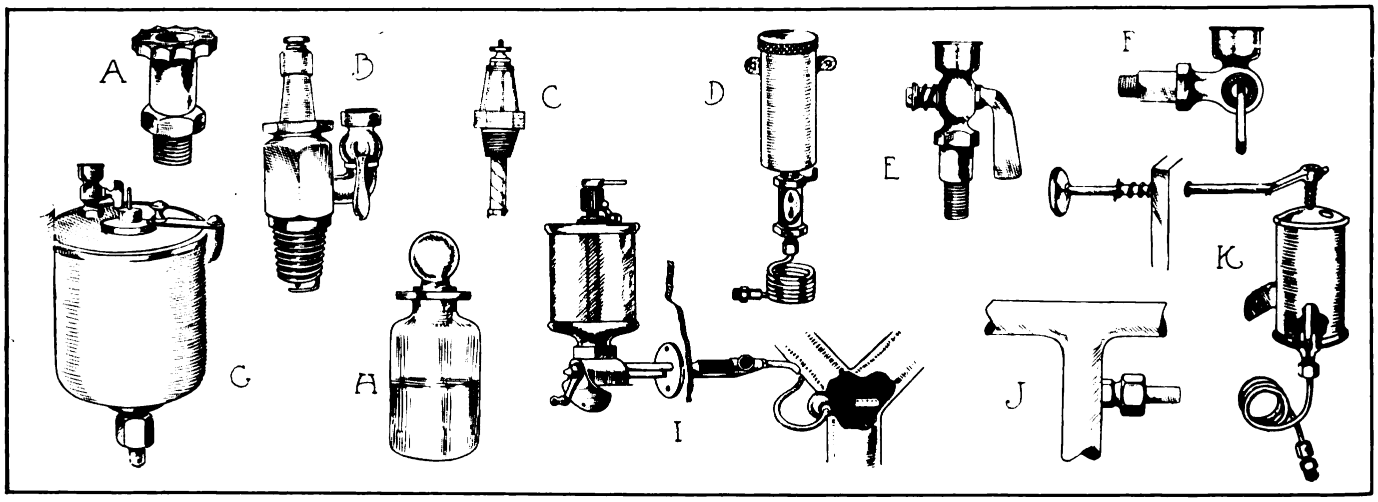
Rich and Lean Mixtures.

Gasoline, or to be more exact, motor fuel, evaporates readily in ordinary temperatures, but when cold the amount of vapor given off will be affected accordingly. It follows, therefore, that a carburetor set for a mixture of proper value in warm weather will, when cold, produce a lean mixture due to the lack of vapor, and starting is rendered more difficult. Even if the vaporizer does perform its function properly the mixture may condense in the intake manifold because of the excessive cold encountered.

While it would appear that the remedy was to increase the amount of fuel in proportion to the air, it must be taken into consideration that the mixture would not be of proper value at higher engine speeds if it were made excessively rich for starting purposes. To overcome this trouble carburetor manufacturers incorporate means for restricting the air or increasing the fuel, or both. These devices attain similar results to those secured by flooding or priming and closing the butterfly air valve, an operation with which most drivers are familiar.

When it is so cold that the engine cannot be started by utilizing these appliances, it will become necessary to employ some means of raising the temperature of the motor until it becomes warm through operation. The most simple method is by priming or injecting fuel into the combustion chambers through the petcocks and restricting the air until the motor is warm enough to run on the normal mixture. As the present fuel is heavy a good starting solution may be prepared by using a 25 per cent. mixture of sulphuric ether and gasoline. It should be carried in a bottle having a ground glass stopper as ether is extremely volatile and evaporates readily.

If the engine is not equipped with petcocks they may be fitted to the exhaust valve caps, or if this is not possible a spark plug having an integral priming cup may be employed. A priming cup fitted to the intake manifold facilitates starting as the fuel is sprayed over the walls of the pipe and makes for a rich mixture. Ether introduced into the carburetor through a priming cup, also aids vaporization. In priming the cylinders should not be flooded.



Priming Devices Making for Easy Starting of Motor in Cold Weather: A, Morgan Priming Cup; B, All-In-One Plug; C, Stallt Plug Heated by Electricity and Utilized in Intake Manifold; D, Nelson Sight Feed Primer; E, Conventional Type of Priming Cup; F, Design for Horizontal Cylinders; G, Priming Cup on Carburetor; H, Ether Should Be Carried in Bottle Having Ground Glass Stopper; I, Buckeye Sure Starter; J, Tapping Intake Manifold for Priming; K, Fowler Self-Closing Primer.

Raising Temperature.

If the car be kept in an unheated building, and the weather be very cold, starting after priming will be made more easy by heating the carburetor and intake pipe. Cover the vaporizer with a rubber cloth and pour the contents of a kettle of hot water over these members. This will prevent condensation of the mixture. Often after priming the motor will explode several times, then stop, necessitating a repetition of the work until the cylinders are warm.

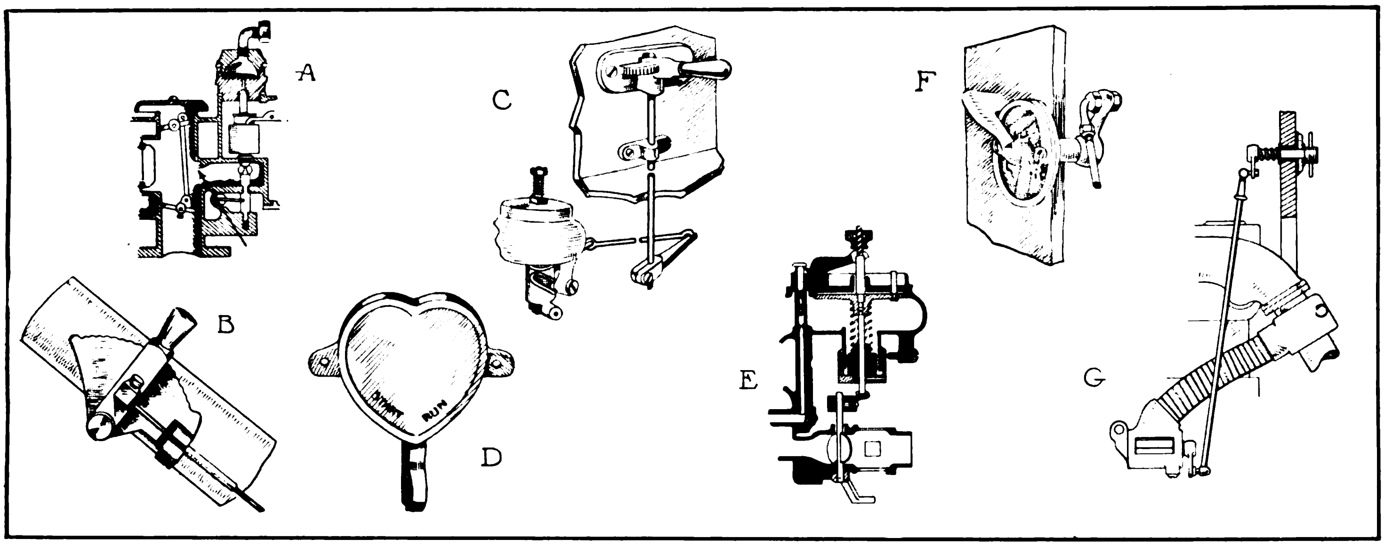
There are a number of priming devices being marketed and several of these are shown in the accompanying illustrations. The principle involved is that of conveying gasoline or a highly volatile fuel to the intake manifold, creating a rich and easily exploded mixture when the motor is cranked. Some designs include a pipe leading from the exhaust manifold so

that after the first explosion the fuel is heated. Others provide means for adjusting the air as well as the flow of the fluid. Being operated from the seat, the driver is saved the trouble of flooding the carburetor and shutting off the supply of air in starting.

Dash Controls.

The carburetor manufacturers are cognizant of the fact that fuel has been growing heavier and have made provision accordingly. Many of the leading designs incorporate dash controls which not only permit of adjusting the mixture from the seat, but restrict the air and enrich the mixture when starting. Others provide auxiliary means for raising the level of the fuel in the spraying nozzle.

Clean fuel, perfectly free from water, and a good spark are important factors in starting a cold motor. It is imperative that the dry cells or storage battery be in good condition and that the spark take place as near dead centre or at the beginning of the firing stroke, as is possible. If the spark be too late and the mixture thin the explosion will be weak. As the majority of carburetors are equipped with means for taking in auxiliary air above certain motor speeds, a few suggestions concerning starting, as well as extracts from the instructions of the maker, will be of value to the driver unfamiliar with cold weather carburetion.



Dash Controls Utilized for Enriching the Mixture and Priming Components of Carburetors: A, Rayfield Construction Includes a Dam Which Is Flooded with Fuel; B, Miller Utilizes Steering Post Control; C, One of the Stromberg Controls for Restricting Air; D, Schebler Dash Device; E, Stromberg Closes Both Fixed and Auxiliary Air Inlets; F, Rayfield Starting Control on Dash; G, Holley Temperature Regulator and Strangler.

Rayfield.

The Findeisen & Kropf Manufacturing Company, Chicago, maker of the Rayfield, advises opening the throttle about one-quarter. More will augment starting troubles. Each Rayfield is provided with a dash adjustment the actuation of which lifts the needle valve, creating a rich mixture. In severe cold weather it is advisable to flood the carburetor by using the priming attachment which fills a dam with fuel. When the motor is cranked the fuel is drawn into the cylinders in the form of a heavy mixture. After the motor has become warm the dash lever should be returned to normal position.

Stromberg.

The Stromberg, made by the Stromberg Motor Devices Company, Chicago, utilizes a combination starting device, dash controlled. When the operating handle is moved to "start," the fixed air inlet passage is closed by a valve and the auxiliary member is also held on its seat. This results in the piston drawing in a very rich mixture. Like the Rayfield, the Stromberg uses heated air from the exhaust, but this serves only to heat the mixture after the first explosions.

Schebler.

Wheeler & Schebler, Indianapolis, Ind., maker of the Schebler carburetors, recommends for models O and L that the mixture at low speed be made slightly more rich in cold weather owing to the heavy grade of fuel. This is obtained by opening the needle valve member. Dash controls are provided with both models and the auxiliary air intake of the O is closed for starting purposes. This design is equipped with means for taking hot air from the motor and it is recommended that the lever be moved to the full open position in winter. The model L is adjustable from the dash, in that moving the lever to "start" creates a rich mixture by eliminating the air. Means for priming are incorporated in all Schebler types.

Holley.

In the Holley carburetor, made by the Holley Bros. Company, Detroit, a strangling device is employed in conjunction with a temperature regulator, the object being to restrict the amount of air and to enrich the mixture. It comprises a flexible metal tube having a scoop at one end and being secured to the exhaust pipe. The other end is fastened to the air intake of the carburetor and is provided with a shutter member, the opening and closing of which is controlled by a handle on the dash. When the valve is closed the mixture is enriched and the first few explosions are productive of heated air. After starting the amount of air is adjusted as required.

C R G.

A priming device creating a fine spray in the intake manifold is utilized in connection with the C R G carburetor, made by the C R G Manufacturing Company, Saugus, Mass. If a pressure feed is employed the main line of supply is tapped and the pipe led to the intake manifold, where the spraying effect is secured through opening a valve. With the gravity feed pressure is obtained for spraying by a small hand pump mounted upon the dash.

Newcomb.

An auxiliary nozzle is used for starting in very cold weather in the Newcomb carburetor, manufactured by the Holtzer-Cabot Electric Company, Brookline, Mass. It is brought into action by rocking the throttle valve back past the closed position when the suction of the piston draws a spray into the cylinders. In severe cold weather the device is assisted by depressing the float, which causes the fuel to overflow into a plunger chamber, further enriching the mixture. The Newcomb has a dash adjustment for starting and operating.

Breeze.

The Breeze Carburetor Company, Newark, N. J., maker of the Breeze, lays great stress upon the Col-Mac exhaust hood for facilitating carburetion, stating that by it air free from atmospheric moisture is taken into the vaporizer and that after the first explosion or so the air is dry and more perfect carburetion is possible. It is also pointed out that hot air is supplied in a few seconds, as it requires but a short time to heat the exhaust pipe.

TRUCK SIZE IN NEW YORK.

Highway Commission Now Considering Bill and Limit Weight Similar to Massachusetts Suggestion.

A bill somewhat similar to the one introduced in the Massachusetts legislature a year ago and referred to the legislature of 1913, is being considered by the highway commission of New York State. The proposition is to limit the size of motor trucks to be used on the state highways, the only roads to which its provisions will not apply being state and county highways having a concrete roadbed of six inches or more in thickness with brick street surface. The New York commission is at present divided between two propositions, set forth as follows:

First Proposition.

It shall be unlawful for any person, firm, association or corporation to draw or propel, or cause to be drawn or propelled, over any state or county highway which has been or may hereafter be improved by the state, or state and county, any vehicle the weight of which shall exceed, in combined weight of load and vehicle, as related to the width of tire, the weight per width as given in the following table.

Second Proposition.

The following regulations to apply only to various forms of macadam and gravel highways as built by the state, or state and county. Combined weight of load and vehicle to be limited to a maximum of 400 pounds per inch of width of tire carrying the same. Under this regulation four-wheeled vehicles carrying evenly distributed loads might be loaded to the following:

Vehicles with	Maximum load, pounds. one axle*	both axles†
1-inch tires	....	1,600
1.5-inch tires	1200	....
2-inch tires	1600	3,200
2.5-inch tires	2000	....
3-inch tires	2400	4,800
4-inch tires	3200	6,400
5-inch tires	4000	8,000
6-inch tires	4800	9,600
7-inch tires	5600	11,300
8-inch tires	6400	12,800
9-inch tires	7200	14,400
10-inch tires	8000	16,000

*First proposition; †second proposition.

EFFECTS LARGE SAVING.

Saurer Truck in Arizona Mining Section Cuts Haulage Expense More Than Third.

Recently the Arizona Southwestern Copper Company installed, as an experiment, a 6.5-ton Saurer motor truck, made by the International Motors Company, New York City. The car has been operated between Yucca and Copperville, Ariz., a haul of 27 miles, and a careful observation was kept of its performances. The results far exceeded expectations, the cost a ton for the haul being reduced from $15 to less than $5. Numerous deep sand washes must be crossed and seven miles of grade from 10 to 18 degrees must be negotiated, but the truck has proved itself equal to the occasion. The following operating figures indicate the cost of each trip:

Gasoline, 19 gallons, @ 30 cents	$5.70
Oil, five quarts, @ 20 cents	1.00
Grease, one pound	.12
Driver, 1.5 days, @ $4	6.00
Total visible expense	$12.82
Interest on investment at 6 per cent. and insurance for 1.5 days	2.11
Depreciation at 10 per cent	2.67
Repairs	2.25
Tires	2.83
Average cost a trip for upkeep and expense	$22.68
Cost a ton a trip	$4.53
Former cost a ton	$15.00
Showing a saving of	$10.46

The saving to the company on each trip over that of the wagon haul is $52.30. With the completion of the company's new mill, permitting haulage from the mill to the railroad, the truck will show a much greater economy, as practically all the transporting will be on a descending grade.

Manager F. E. Grable of the Universal Truck Company, Boston, distributor of the Universal trucks, made by the Universal Motor Truck Company, Detroit, recently gave a demonstration of the utility of the vehicle to a furniture dealer in Waltham, Mass., when the car left the Boston garage at 4:20 in the morning, reached Waltham at 5:25 and left at 10, with a three-ton load of furniture, including piano, for South Berwick, Me. It arrived there at 8 in the evening, left at 11 the same night and reached Waltham at 8:25 the following morning. The distance travelled was 201 miles and 33.5 gallons of gasoline and five quarts of oil were used. The machine averaged 10.5 miles an hour and completed a very satisfactory trip.

CORRESPONDENCE WITH THE READER.

Priming Intake Manifold.

(22)—I am driving a Model T Ford delivery car and am experiencing considerable trouble in starting after the engine has become cold. There are no petcocks on the motor and I wish to fit an attachment so that the engine may be primed for starting. Can you give me any suggestions?

OWNER-DRIVER.

Cambridge, Mass., Dec. 5.

There are a number of priming devices suitable to the car mentioned. A spark plug having an integral cup is shown elsewhere. This is made by the Frontier Specialty Company, Buffalo, N. Y., and is on sale at the majority of supply houses. Various priming devices for conveying fuel to the intake manifold also are described in this issue.

One may be made, however, and in an accompanying illustration the arrangement is depicted. The material required consists of an oil cup of the sight feed type and having a snap lever for controlling the flow of the fluid. These members hold from .625 to 18 ounces. One having a capacity of a couple of ounces would serve.

It is secured to the dash by straps or other suitable means and a hole is bored in the dash to allow the copper tube leading from the cup to the intake manifold to pass. The intake manifold is drilled and tapped to take a connector to which is secured the tubing. A reducer will be necessary to connect the small tubing to the oil cup member.

The operation of the device is very simple. The snap lever is moved to allow the fuel to flow and the amount may be regulated by the knurled screw with which each cup is provided. It could be so set that a few drops would flow or a small stream would be secured. In very cold weather the fuel could be made more volatile by employing 25 per cent. of sulphuric ether. The material can be secured at any supply house and the cost will be moderate. It is advisable to employ annealed tubing.

Magneto Not Faulty.

(23)—We employ a converted pleasure car and recently my driver got stalled in the country. He 'phoned in that he could not start the engine on the battery or the magneto. The magneto is a Splitdorf and was overhauled a few weeks previous to the trouble. We sent out a man from a garage who started the motor after a little work. He reported that the magneto was to blame, stating that the trouble was in the circuit breaker, but would not explain how to remedy this if it occurred again. Our driver is a good operator and understands ignition fairly well, but reported that although the batteries were good he could not get a spark. Could you advise me as to the trouble?

W. L. R.

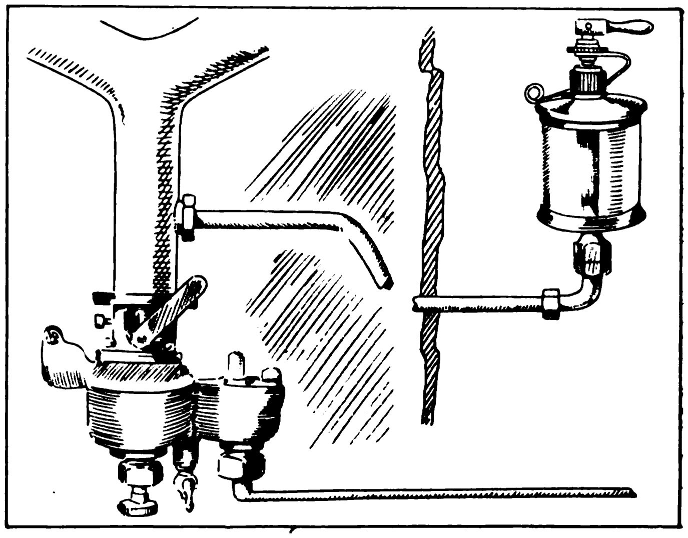
Torrington, Conn., Dec. 4.

It would appear from the fact that the repairman remedied the trouble easily the fault was due more to the workman who overhauled the magneto than to the instrument itself. It is very possible from the meager description given that in replacing the breaker box the repairman who cleaned the instrument did not replace and lock the cover properly, and that it jarred loose, preventing contact of the brushes on the cam.

With the magneto referred to, when the motor is started on the batteries, the current is led to the circuit breaker by a wire connected to a terminal on the brass cover. This terminal is fitted on the inside with a brush or brushes making contact with the cam which makes and breaks the primary current in a manner similar to the timer or commutator employed with the coil and battery system of ignition.

The battery or low-tension current is interrupted by the circuit breaker and led to the coil, where it is built-up into a high-tension current. It flows back to the distributor of the magneto, so-called because it distributes the induced current to the proper cylinder.

If the wire leading from the battery to the terminal above referred to were broken or the brush were not making proper contact, it would be impossible for the current to reach the circuit breaker. The Splitdorf magneto is easily disassembled; that is, the only parts that require any attention, and the cover to the circuit breaker is retained by two small nuts. The Splitdorf Electrical Company, Newark, N. J., or the agent of the car, will supply an instruction book which will enable the operator to remedy troubles of a similar nature.



Method of Fitting Device for Priming Intake Manifold from the Dash. Illustrating the Col-Mac Utilized for Conveying Heated Air to the Carburetor and the Connections.

Battery Output in Winter.

(24)—Am I correct in understanding that a storage battery is affected by the cold and that you do not get as much current in the winter as in warm weather?

READER.

Kenosha, Wis., Dec. 15.

A storage battery is affected by the cold in that its output is impaired; that is, the voltage remains practically the same but the amperage is less. Therefore, it is advisable not to rely upon the cells giving as much service in the winter as in the summer.

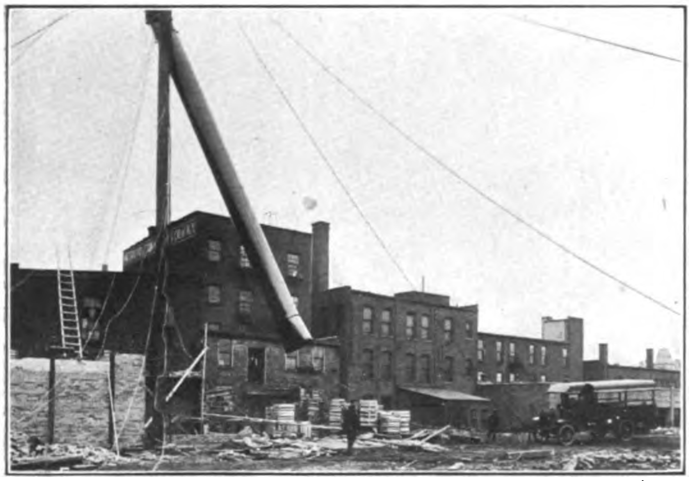
Commissioner Edwards of Salem, Mass., who has charge of the street cleaning department, will ask the aldermen to make an appropriation for 25 motor trucks to be used as garbage wagons, to take the place of the horse drawn vehicles now in service. Mr. Edwards has figures proving the economy of his recommendation.

WHITE PLACES STEEL CHIMNEY.

Three-Ton Truck Demonstrates Its Economy in Special Work of Time and Labor.

An example of the almost innumerable uses that can be made of a motor truck was seen a few days since in Cleveland, O., where a White three-ton truck was utilized to place a very large sheet steel chimney. The big tube was to be installed on a base 12 feet above the ground at the boiler house of the Belle-Vernon-Mapes Dairy Company at Cleveland, and its great length and diameter made it extremely difficult to handle. The weight was about 4500 pounds and it was necessary to lift it above the brick furnace and then lower it into position.

A huge timber was utilized as a derrick and after the tackle had been rigged this was raised upright beside the furnace and supported by guys. A sling was then carried about the stack and to this the lower end of the tackle was made fast. The wire rope was carried through a block at the base of the derrick and made fast to the truck, and when all was in readiness the machine was started and lifted the stack to a height where it could be swung and lowered into place. The work was quickly done when the preparations had been made, and the truck was needed but a comparatively brief period. The economy of the truck in saving labor and time appealed very strongly to the men doing the work, and they were of the opinion that machines could be used for hoisting purposes with as much success as for haulage.



Hoisting an 80-Foot Metal Stack into Place, 12 Feet Above the Ground, with a Three-Ton White Truck.

REOS IN CALIFORNIA.

Los Angeles Owners Report Satisfactory Service and Figures Indicate Economical Operation.

The 1500-pound Reo trucks, made by the Reo Motor Truck Company, Lansing, Mich., are put to many uses in various parts of the country. In Los Angeles, Cal., a large number of these vehicles are utilized, the performances of some of them being noteworthy. Carrying an overload that frequently amounts to 500 pounds, the little truck used by the Grande Fruit Company to deliver fresh fruit and other produce to widely separated stores in all parts of the city, covers scores of miles a day and the average daily operating expense does not exceed 50 cents.

Another truck that gives excellent service is a Reo owned by the Gibson market of West Pico street. Averaging between 60 and 70 miles each day, it covers this distance on three gallons of gasoline. The fact that the vehicle does not carry heavy loads accounts in part for this remarkable mileage record. A Reo machine in the service of the J. W. Hallman Hardware Company, carrying loads that vary from 1500 to 2000 pounds, averages between 12 and 13 miles on a gallon of gasoline and covers ordinarily 50 miles a day. These are fair samples of the service that these sturdy and economical little cars daily perform.

PIERCE-ARROW'S RECORD SERVICE.

Covers Over 19.000 Miles in Los Angeles on Original Set of Tires and Pleases Owner.

A remarkable record of service given by a five-ton Pierce-Arrow worm driven truck has just been received by J. B. Livesey of the truck department of the W. E. Bush Company, Los Angeles, Cal., distributor for the product of the Pierce-Arrow Motor Car Company, Buffalo, N. Y. The vehicle in question is owned by the Motor Transportation Company of Los Angeles. Since March it has travelled 19,054 miles and delivered 5450 tons of freight. In performing this work it has averaged 5.2 miles to a gallon of gasoline and 261 miles to a gallon of cylinder oil.

During the last four months the truck has been in service 20 hours a day. In September it covered an average of 127.6 miles a day or 3822 miles for the month. In commenting upon this performance the officials of the Motor Transportation Company write as follows: "We wish to say that the truck travelled the entire distance mentioned on the original set of tires, which we think, with the other data taken into consideration, makes a record that would give food for thought and by which the Pierce-Arrow worm driven truck speaks for itself."

The Edison Storage Battery Company, Orange, N. J., has recently distributed to electric vehicle engineers and others having use for them handsome leather covered binders containing a series of data sheets relating to the Edison batteries. The 41 sheets contained in the binder are to be supplemented from time to time by similar information, and provision is made for its preservation and use. The binder and data are a decidedly useful addition to the reference library of any person having to do with Edison batteries, being compiled with extreme care and containing facts that will frequently serve an excellent purpose.

THE A B C OF MOTOR TRUCK IGNITION.

Part V—Outlining the Various Systems Utilized with the Commercial Gasoline Vehicle, Their Components and Application in Practise—Wiring Single and Multiple Coils with Dry Cells, Storage Batteries or Mechanical Generator.

By C. P. Shattuck.

IN THE previous installment the primary and secondary circuits were outlined, and the method of converting the low-tension current derived from the battery into high-tension for igniting the mixture was explained. It also was shown that the function of the timer or commutator was to break the flow of the primary or battery circuit at the proper instant and that the spark took place in the combustion chamber approximately at the same time.

As the care and maintenance of the ignition system is an important factor in commercial car service, and as previously explained it is essential that the operator be familiar with the principles of ignition, it will prove of value to consider the installation of the simpler form—the chemical battery and induction coil. By familiarizing himself with the operation of the components of this type the driver will be enabled to make repairs while on the road and the knowledge also will form a basis for the study of the mechanical generator, or magneto. The practical experience acquired will facilitate the work of the overhaul.

Considering first the application of a high-tension system to a single-cylinder motor: The components required comprise a single-unit induction coil, a source of current (dry cells, for example), a spark plug, commutator, switch and high and low-tension wires. The importance of high grade wiring, properly attached terminals and good connections has been explained. Assume that a set of six dry cells is to be utilized as the source of current, and that they are to be wired or connected in series. When so connected there will be two free ends or two terminals, one being the carbon, or positive +, and the other the negative —.

It will be remembered that in order for electricity to flow a path or circuit must be completed, and it is assumed that the current leaves the carbon or positive pole of the battery and returns, or re-enters the cell by the way of the zinc or negative. By referring to Fig. 21 it will be noted that a wire is secured to the zinc terminal of the battery and led to the ground. Any metal part of the chassis may be employed as the ground, and usually the wire is secured to the frame. This completes one side of the primary circuit.

The second lead from the cells, the positive, is attached to the primary or battery terminal on the coil. To break or open the circuit and thereby prevent the passing of the current through the circuit a switch is utilized and it may be attached to and made a part of the coil, or placed on the dash or in some other convenient location.

If the two leads from the cells were connected current would flow, but if a switch were incorporated in the line and opened, the flow would be checked or stopped, to be re-established when the switch lever was moved to what is designated the "on" or "battery" position. When it is desired to stop the operation of the motor, the lever is moved to the "off" position, which breaks the circuit.

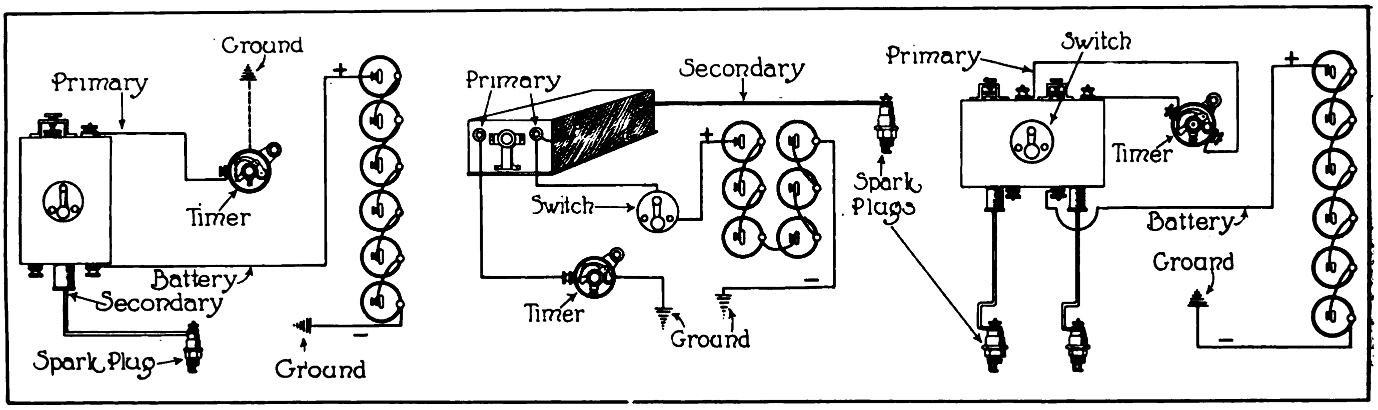


Fig. 21—Depicting Wiring Plan for Single and Two-Cylinder Ignition with Dry Cells as a Source of Current: At Left, Vibrating Type of Coil Having Three External Connections; Centre, Box Design with Two Primary and Two Secondary Terminals; At Right, Primary and Secondary Connections of Two-Cylinder Motor.

As it would not be practical to utilize the coil or dash switch for breaking the primary circuit when the battery current is strengthened, the timer is employed for this purpose. This is in reality a switch, in that it establishes and breaks the primary circuit at the instant the mixture should be ignited by the flame at the gap of the spark plug.

It was shown at Fig. 20 that a metal member or block is imbedded in non-insulating material, usually fibre, and that a rotating metal roller makes contact at a certain degree of its rotation. When the roller is in contact with the fibre the primary circuit is not established, although the switch on the coil may be closed. Upon the roller touching the metal block, the

circuit is completed, and as shown at Fig. 21 (assuming that the coil switch is closed) the primary or battery circuit is completed and current begins to flow.

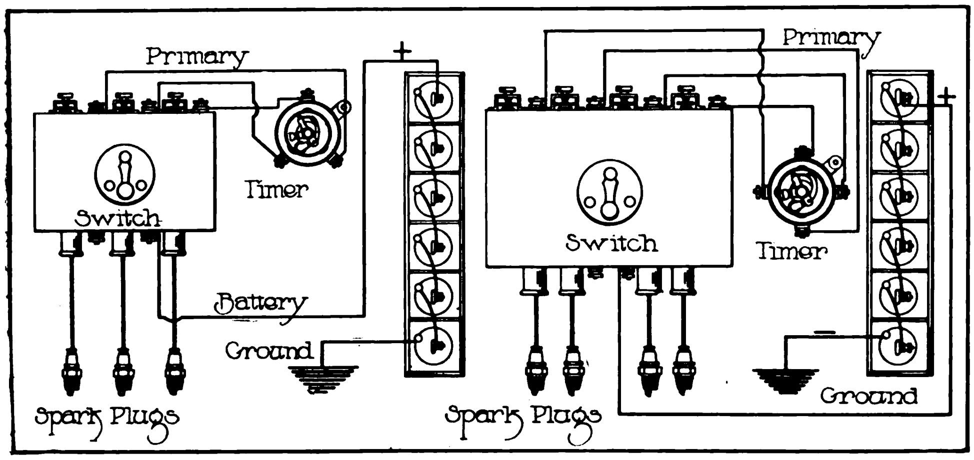

Fig. 22—Illustrating Wiring Plans for Three and Four-Unit Coils Utilized with Three and Four-Cylinder Motors.

It will be noted that a wire leads from the insulated terminal on the timer and is attached to the top of the coil. With the circuit completed current is flowing from the batteries to the coil, the core of which is converted into an electric magnet attracting the vibrator spring to it and thereby causing the platinum contact points to separate and thus break the circuit. This is denoted by a buzzing noise and takes place when the metal members of the timer are in contact, but ceases when the connection is broken either at the timer or by means of the switch. It is at the instant of breaking that the secondary current is created.

The high-tension current is conveyed through a heavily insulated cable to the spark plug, where it jumps the gap, creating a flame, and as the base of the plug or that part screwed into the cylinder is of metal, the current continues to flow through the motor, frame and wire back to its source. It should be borne in mind that a path or circuit must be established for the secondary as well as the primary currents.

Wiring Box Type of Coils.

On the box type of coil shown at Fig. 21 there are four terminals, two primary and two secondary. It will be noted that one primary and one secondary are coupled, and that a wire is led to the centre terminal of the switch. One lead from the dry cells is grounded while the other is secured to the terminal of the battery. From the primary terminal of the coil is led a wire to the insulated terminals of the timer.

Two-Cylinder Units.

The wiring of a two-cylinder motor may be accomplished successfully by applying the same principle as with the single-unit, the only difference being that two cylinders are to be fired instead of one. The simplicity of the wiring plan is shown at the right of Fig. 21 and it will be seen that one side of the battery circuit is grounded as with the single-unit system. Two coils are utilized and conventional practise places them side by side in a single casing, or coil box as it is termed.

Each unit acts independently of the other and as indicated in the drawing a separate cable is utilized to convey the high-tension current to the spark plug. As there are two cylinders, it follows that each will require an independent spark so the timer is provided with two metal blocks, the terminals of which are connected by wire to the respective binding posts on the coils. The operation of the switch is similar to that of the single-unit coil except that means are provided for breaking simultaneously the primary current to both.

It will be noted in the wiring plan that a wire is led from one terminal of the timer to the right hand binding post of the coil, which for convenience will be designated as the No. 1. The secondary wire from this coil is led to the spark plug of the No. 1 or first cylinder to be fired. The second or remaining lead from the timer is secured to the No. 2 coil, the cable of which leads to the spark plug of the second cylinder. As the roller of the timer rotates it will make contact first with the No. 1 block, firing the first cylinder, then with the second terminal of the commutator, causing a spark in the combustion chamber of the second cylinder. This is repeated so long as a source of current is provided and the components of the system perform their function.

Three and Four Units.

Any number of units may be utilized, depending upon the number of cylinders. At Fig. 22 are shown the wiring diagrams of three and four-cylinder units, and with dry cells as a source of current. It will be seen that the timer is provided with terminals corresponding to the number of units. All of the wiring

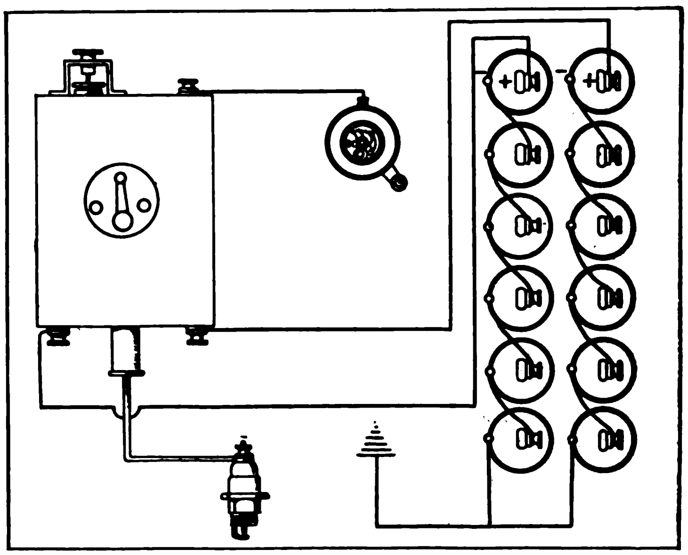

Fig. 23—Showing Wiring Plan for Two Sets of Dry Cells Controlled by a Single Switch.

plans presented and discussed make use of but one source of current, a set of six dry cells, but two independent groups may be employed, or a chemical and

mechanical generator may be utilized, as will be explained.

The majority of coils, be they single or multiple-units, are provided with a two-throw switch; that is, they are so arranged that two sets of batteries may be used. At Fig. 23 are shown two groups of cells and the method of wiring, as well as the independent connections to the switch. The batteries are wired in series and it will be seen that the individual leads from the zinc or negative terminals are both led to the ground or frame. To economize in wire, the insulation may be removed from one lead and the other spliced to the bare wire, after which it should be taped.

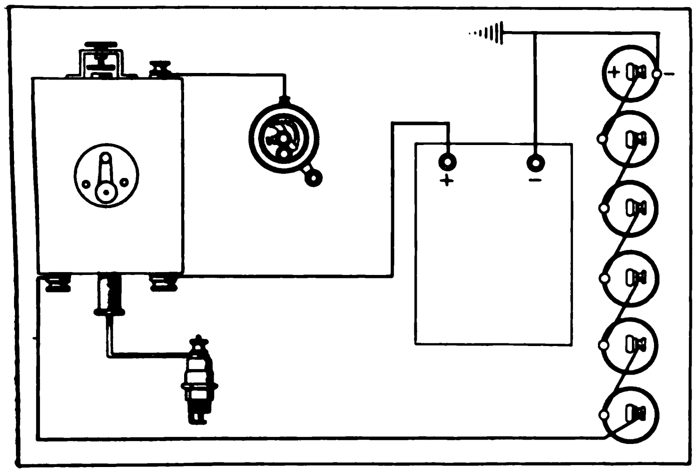

Fig. 24—Outlining Wiring with Dry Cells and Storage Battery, Showing How Polarity Should Be Observed.

As there are two sets of cells it is evident that two carbon or positive terminals are free and these are connected by wire to the right and left hand battery terminals of the coil box as illustrated in the drawing. Each of these terminals is connected by wire inside the coil box to the terminals on the switch, which are indicated in the drawing by small circles. The top of the switch lever is also connected to the primary circuit of the coil.

Normally a path is not established when the lever is in a vertical position as shown in the drawing, but upon its being moved to the right, the circuit is established as the lever, being of metal, forms a connection. Current will flow, provided proper contact is made at the timer, from the right hand set of batteries. Upon moving the switch lever to the left the other or reserve set of cells is brought into service and the first named batteries are cut out.

Utilizing Cells and Storage Battery.

The source of current may not always be dry cells, as a storage battery may be utilized, or both. Wiring dry cells in two sets in series is a simple matter as the novice is guided by the positive and negative terminals, but when a storage battery is to be employed with dry cells for reserve or vice versa, it is imperative that the polarity be observed. The storage battery is usually marked, the negative being denoted by — and the positive by +, and in wiring these members care must be taken or the cells will become exhausted through short circuits.

At Fig. 24 is depicted the wiring of a set of six dry cells and a storage battery. It will be noted that the wire leading from the negative pole of the storage member is spliced to the negative lead from the dry cells, then continued and grounded. The positive lead from the storage is connected to the right hand battery terminal on the coil while that from the dry cells is secured to the left hand member. By utilizing the switch as above described either source of current may be employed.

Mention has been made of the mechanical generator. There are several types manufactured and that depicted at Fig. 25 develops a low-tension current, the voltage of which is approximately the same as a set of six dry cells or the conventional type of ignition storage battery. It may be employed with dry cells, in which event the latter are utilized for starting the motor, then cut out and the generator employed for supplying the current.

Referring once more to Fig. 25, it will be seen that there are two poles or terminals on the magneto, a negative and positive, and one of these is grounded. The other is led to one side of the switch. When the switch lever is moved to the left and the circuit closed, current flows from the generator in practically the same manner as it would from a battery. The drawing shows a set of four dry cells, which in this instance is utilized for starting. The arrangement of the timer and secondary wire is the same as with the other systems, but it will be noted that in this instance the left hand lower terminal on the coil is utilized for making the desired connection with the commutator. With a generator of the type outlined, the electricity is led to the coil and built up into a high-tension current in

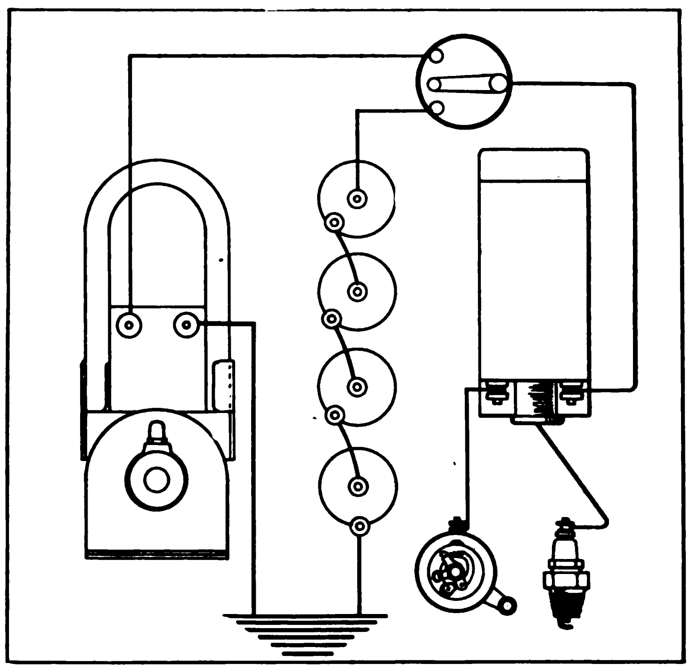

Fig. 25—A Mechanical Generator May Be Utilized with Dry Cells or a Storage Battery, Providing Two Separate Sources of Current.

the same manner as when the source of current is chemically derived.

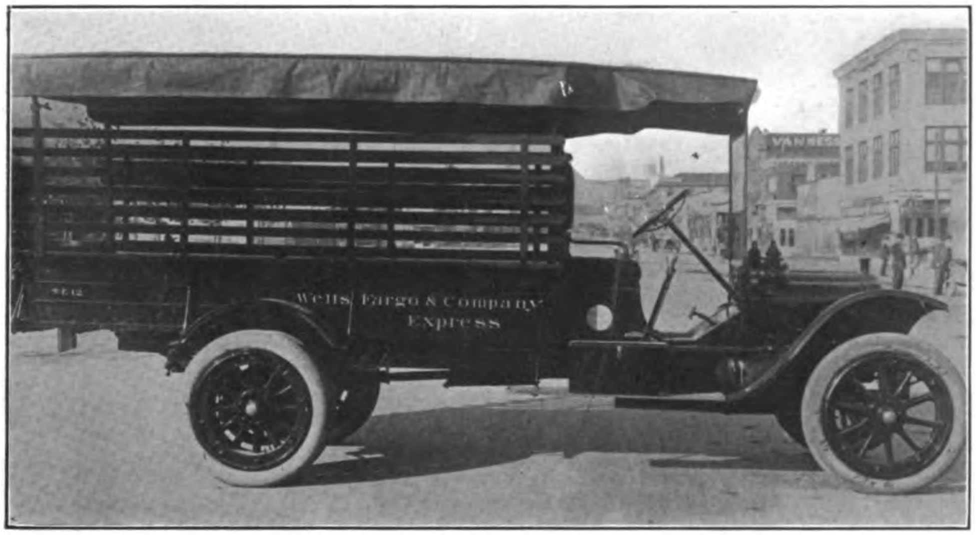
(To Be Continued.)

WHITES FOR EXPRESS COMPANY.

Wells Fargo Company in San Francisco Receives First Machine on Recent Order.

An accompanying illustration presents the White 1.5-ton truck, made by the White Company, Cleveland, O., which is the first to be delivered to the Wells Fargo Express Company, San Francisco, Cal., on a recent order for four of these vehicles. Inasmuch as the express companies of the country have been experimenting with several types of vehicles before making decision in the matter of ordering in quantities, it must be accepted as demonstrated that the White trucks are able to satisfy the requirements of this concern in this particular field.

The body is specially designed for the work it is to perform, being fitted with an extension top to provide for carrying larger loads should occasion require. The location of the package compartment is with special reference to weight distribution. The pneumatic tires, single in front and dual in the rear, are stock equipment with this size of White vehicles.



One of a Fleet of 1.5-Ton Whites Recently Ordered by Wells Fargo Express Company.

PACKARDS SOLVE DELIVERY PROBLEM.

Worcester Concern Extends Its Service to Include Over Sixty Towns and Secures New Business.

The Denholm & McKay Company, Worcester, Mass., which operates the large dry goods business known as the Boston Store in that city, has just installed a new suburban automobile delivery service that is covering practically every city and town within a radius of 25 miles. The company, by the use of a fleet of Packard trucks, made by the Packard Motor Car Company, Detroit, has greatly extended its delivery zone and is giving twice-a-week service to over 60 towns, operating on a regular schedule. The innovation is not only a decided impetus to the trade of the Denholm & McKay Company, but enables the people in the towns served to send in mail or telephone orders and have their goods delivered at their doors in minimum time and without extra charge.

SAVES ON FERRY TOLLS.

Peerless in Milk Delivery Makes Important Reduction in Addition to Other Economies.

Owing to its ability to carry heavy loads over steep grades in much less time than horses, the five-ton Peerless truck, made by the Peerless Motor Car Company, Cleveland, O., and operated by the Howell Condensed Milk & Cream Company of Jersey City, N. J., is eliminating over $3000 a year in ferry tolls alone, in addition to all the usual savings that result from successful motor truck operation. Every night the company hauls a large quantity of milk from Jersey City to a point two miles in the interior of Staten Island. The truck makes two trips with 100 40-quart cans, each weighing 110 pounds.

The present route covers a run of eight miles from the distributing station in Jersey City to the Bergen Point ferry and another of two miles after reaching Staten Island, making a round trip of 20 miles, or 40 miles for the night's work. The ferry tolls are 35 cents for each passage or $1.40 a night. It was impossible for the teams which formerly did the work to take this route because they could not cover the 10 miles over steep grades fast enough to deliver the milk on time.

Two teams formerly left the distributing station and proceeded by way of the Erie railroad ferry to New York. The toll for this trip was $1 a team. Across Manhattan it was one mile to South Ferry and the ferry toll from South Ferry to Staten Island was $1.50 for each team. This amounted to $10 a night for two round trips for two teams as against $1.40 for the truck. As the motor vehicle works every night in the year the annual saving is $3139. The Howell company is also now running this truck in the daytime.

A new concern at Johnstown, Penn., of which Adam Trabold is the head, has begun the manufacture of commercial automobiles. Its first truck, which was sold to the Germania Brewing Company of Johnstown, is reported to have given good service and six more will be produced in the near future. It is Mr. Trabold's intention to build vehicles with capacity from one to five tons suited to any purpose or business. The one-ton trucks will have a 35-40 horsepower motor and 116-inch wheelbase.

NEW WATER-COOLED KELLY TRUCKS.

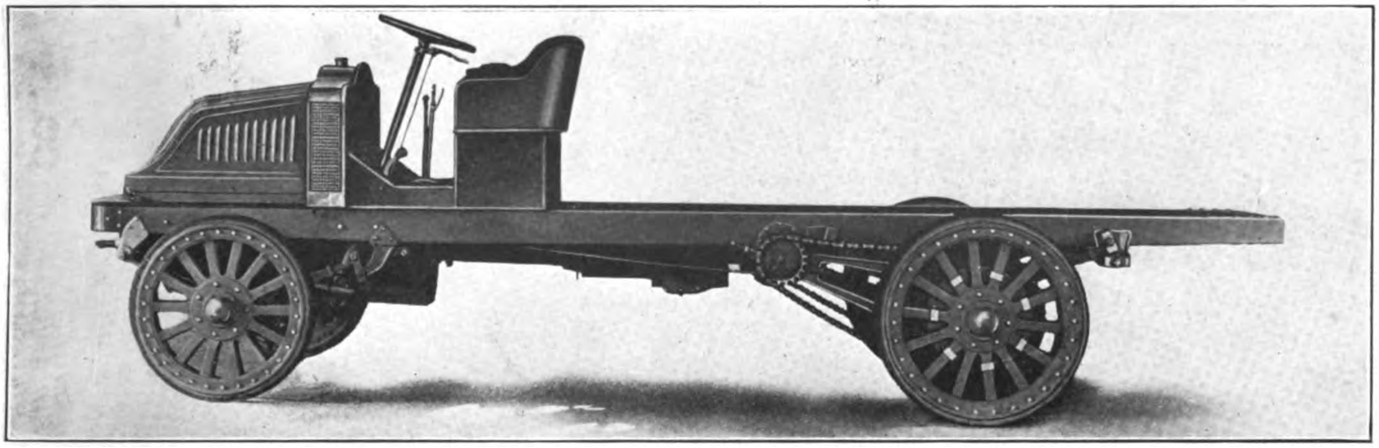
TWO new machines, both of the water-cooled motor type, have been announced by the Kelly-Springfield Motor Truck Company, Springfield, O., which has succeeded the Kelly Motor Truck Company. The original productions were vehicles with a motor cooled by air circulated about it by a blower system. The company has been given a new name and its capital has been greatly increased, and its facilities correspondingly developed. The statement is made by the company that it has all the advantages of a new concern with the experience of an old one, that with an engineering department of undoubted capacity and experience it is prepared to build what is believed to be the best vehicles in the country, and that with its enlarged plant it will have capacity to produce 1200 machines during 1913.

It is emphasized that it is not purposed to utilize tools or material that were used in the building of the old models. In every respect the machines will be new. It is also made clear that with its long experience the engineering department has learned what not to do in motor vehicle design and construction.

Aside from the transition from air to water cooling the company has made a very radical change in design, and that is in the construction of a chassis frame. Instead of endeavoring to secure rigidity, the frame is to be made as elastic as possible, so that there will not be a resistance from the members under road or load stress that will cause strain of parts or excessive thrust, with loosening of rivets, bolts and other connections. To the contrary the frame has been designed so it will yield to the tendencies to distortion, and yet will maintain the original form when relieved of such strains.

This construction will, it is maintained, give a vehicle that will have every quality that could be sought and will not be susceptible to the influences that are now regarded as productive of extreme deterioration. The frame is constructed of very heavy pressed steel channel section, and it has but three cross members, one at either end and the third in the centre. The mechanism is protected against the distortion by universal joints and swivelled connections, which will permit a very much greater range of movement than the machine could ever be subjected to.

The motor is installed in the frame on three points, two at the forward end and the third at the rear. The clutch is coupled to the driving shaft by a double universal joint. The driving shaft is enclosed in a torque tube and the front end of this tube is connected to the centre cross member of the frame by a double swivel joint. The torque tube is carried by the jackshaft housing and the jackshaft housing is supported in the frame by globes and sockets, the globes being free to move in these sockets. The forward ends of the radius rods are mounted on the jackshaft housing with double universal joints, and the rear ends of the radius rods are connected at the rear axle with double swivel joints. From this system it will be understood that there will be elimination of power absorbing stresses whenever the machine is subjected to the shocks of rough roads or to heavy or unequalized loading. In the development of this construction extreme care was taken to observe conditions and results, and it was the experience that there was a decided practical benefit.



Side View of the Chassis of the K-40 Three-Ton Kelly Truck, the Latest Product of the Kelly-Springfield Motor Truck Company.

The one and three-ton chassis differ in two particulars, the one being the motor and the other the jackshaft. Because of this fact both motors and both jackshafts will be described, but the other details will apply to either.

The larger motor is a four-cylinder, four-cycle, water-cooled T head type with the cylinders cast in pairs from a high grade of fine gray iron, with bore of 4.5 inches and stroke of 6.5 inches, having a rating of 38.75 horsepower at 900 revolutions, which is the maximum speed permitted by the governor. The ratio of bore to stroke is one to 1.47, which is maintained to afford unusual power production at slow speeds, which is the work expected of a service vehicle engine. The water spaces are extremely large and circulation has free flowage about the entire length of the explosion chamber and the combustion head. Much care is taken in finishing the cylinders and the pistons. The crankcase is aluminum, cast in two sections, the upper half

of which carries the main bearings, the lower serving as an oil reservoir. In the right (exhaust) side of the top section are two large handholes that are covered with easily removable plates, and through these the crankshaft, camshaft and connecting rod bearings may be reached, examined and adjusted. There is a large drainage cap through which the crankcase may be cleaned. The forward end of the crankcase is somewhat unusual in appearance from the fact that provision is made for an outside cross shaft. In the assembly of the crankcase is noticeable a feature of construction that obtains throughout the motor, and that is the use of through bolts and castellated nuts, so that there will be little chance of slackness of parts from vibration or road shock. In fact, special provision has been made to insure against this condition resulting.

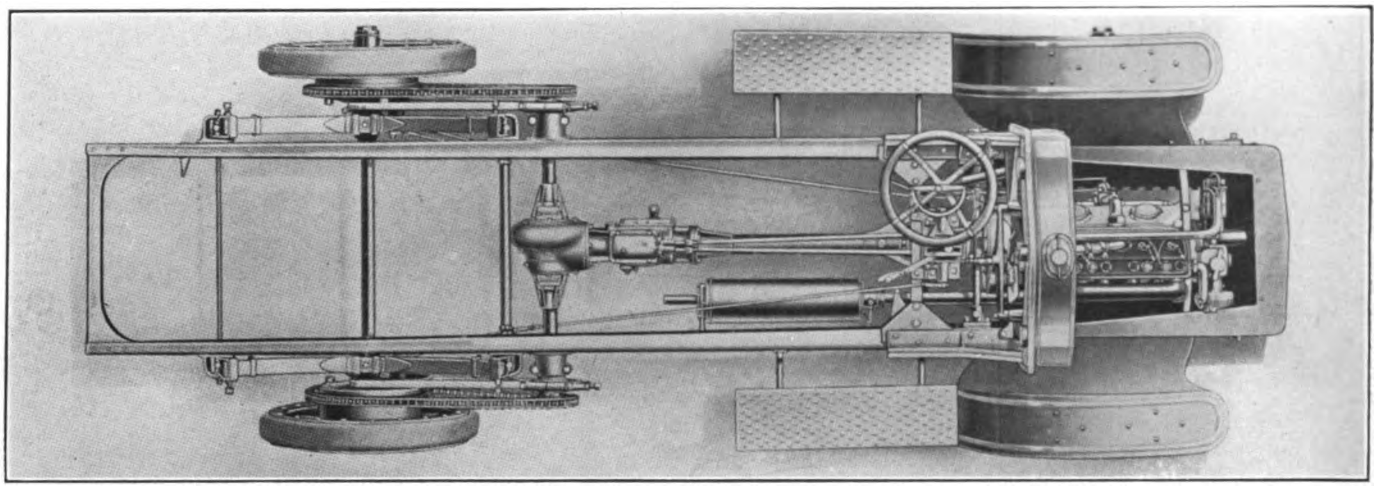
The crankshaft is a 3.5 per cent. heat treated nickel steel drop forging, 2.375 inches diameter, which is carried on three main bearings, the front and centre bearings being 3.3125 inches length and the rear bearing 5.375 inches length, this giving a total of 12 inches of longitudinal bearing surface. The crankshaft extension is of unusual length and it is supported by the long neck of the crankcase. The timing gears drive the right and left camshafts in the usual manner, and there is an extra gear that operates the cross shaft, which drives the water pump at the right side and the magneto at the left. The purpose of the additional gear is to insure against the wear that is generally experienced with spiral gears having too acute angles.

The camshafts are of liberal proportions and of high quality steel, carefully ground and treated to insure long endurance. The pistons are 6.25 inches length and the wristpins are 1.53125 inches diameter. The connecting rods are extremely light, of chrome vanadium steel, with big ends 2.125 inches diameter and 3.125 inches length. The small end bearing length is 1.375 inches. The valve action is conventional, the ports being 1.625 inches diameter and with such clearance as to insure the best scavenging and full charges of fresh fuel. The valve mechanism is completely enclosed and at either side of each cylinder unit is an aluminum cover plate that may be removed by loosening a single finger nut, which fully protects the moving parts against the accumulation of abrasive substances.

The engine is lubricated by a dry base self-contained force feed system, the oil being stored in a reservoir in the base of the crankcase which has a capacity of 2.75 gallons. A centrifugal pump creating high pressure forces the lubricant through a system of tubing to all the bearings through a hollow crankshaft and to all the timing gears, the normal flowage being about 2.5 gallons a minute at maximum engine speed. The oil drains back to the reservoir and is filtered and used over and over. There is no question that the bearings will be supplied so long as oil is contained within the crankcase.

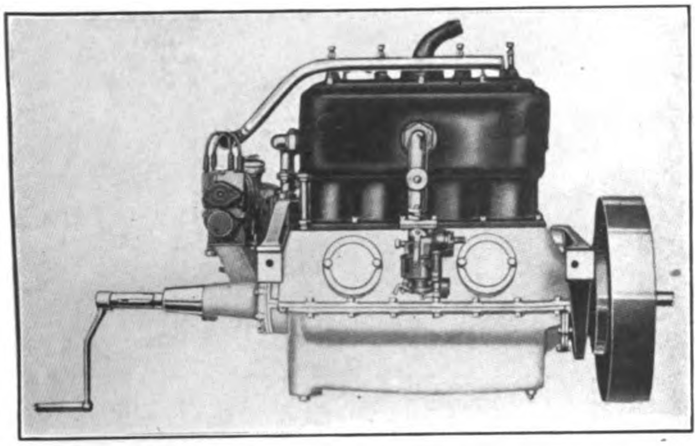
The engine is cooled by a circulation of water forced by a centrifugal pump driven by the cross shaft at the forward end of the motor through the water jackets and a tubular radiator placed back of the engine and incorporated with the dash. The radiator is supplemented by a straight bladed fan driven by a belt from the flywheel. The greatest cooling efficiency is obtained and the radiator protected against the stresses of the chassis distortion. The fuel is contained in a 20-gallon tank and is carburetted through a carburetor at the left side, the manifold being large and very free from curves. The fuel is controlled by a governor of the vertical loose ball type which is perfectly enclosed. The connection to the intake manifold is but an inch in length and the manifold and the carburetor may be removed without removing the governor. The ignition is by an Eisemann high-tension magneto fitted with a governor that automatically advances and retards the spark.

The clutch is a cone type with leather facing with springs that permit ease of engagement and certainty of control when starting. The clutch shaft is coupled to the drive shaft by a double universal joint and the main driving shaft is enclosed in a torque tube that is supported at its forward end in the centre cross member of the frame by a double swivel joint. The transmission gearset, incorporated with the jackshaft, is a selective sliding gear type with three forward speeds



Top View of the K-40 Three-Ton Kelly Chassis, Showing the Flexible Construction of the Frame and the Location of the Power and Driving Mechanism.

and reverse, the shafts being 1.625 inches diameter. The gears have 1.375 inches face. The shafts are mounted on roller bearings. The case has an inspection plate at the side so that it may be examined or the lubricant replenished without raising the floor boards of the body. The ends of the jackshaft housing are mounted in globe sockets at the sides of the chassis frame. The jackshafts are carried on taper roller bearings and are 1.625 inches diameter. The construction is the full floating type. A cover plate on the shell affords instant accessibility. The drive to the rear wheels is by side chains. The radius rods are so designed that the braking strain is taken by the solid steel forging and not by the adjusting screw, while the adjustments can be made very quickly.



Inlet Side of the En Bloc Motor of the One-Ton Kelly Wagon, of 30 Horsepower.

The frame is mounted on semi-elliptic springs 44 inches length forward and 56 inches length at the rear, so that the body rides easily and the road shocks are practically absorbed. The front axle is a carbon steel drop forged I section 2.5 by four inches, with the spring seats forged integral. This is fitted with 3.5 per cent. nickel steel steering knuckles. The spindles are fitted with large sized roller bearings. The rear axle is the same material and is three by 4.375 inches. The spindles are equipped with roller bearings. These axles are fitted with spring clips that extend through them, fastening the springs very securely. The wheel equipment is the conventional artillery type with spokes 2.5 by three inches. These are shod with 38 by five-inch single solid tires forward and 42 by five-inch dual tires at the rear. The brakes are internal expanding in drums on the rear wheels 20 inches diameter, the service brake shoes having three inches face and the emergency brake shoes 2.5 inches face.

The drive is at the left side with pedals for actuating the clutch and the service brake and hand levers in the centre for operating the speed changes and the emergency brake. The fuel supply is regulated by a hand throttle on the steering column. The standard wheelbase is 150 inches with tread of 68 inches forward and 72 inches rear. Options of 130 and 172 inches wheelbase are offered to buyers. The standard loading space is 12 feet three inches, and the length with other optional wheelbases is nine, 15 and 17 feet.

The motor for the 2000-pound chassis is an L head type with the four cylinders cast en bloc and with bore of 3.75 inches and stroke of 5.25 inches. It is rated at 30 horsepower. With this construction all of the moving parts are fully enclosed and protected and the same accessibility obtains. In every respect the engine has the same features and characteristics of the larger, the cooling being extremely efficient and accomplished in the same manner, by a centrifugal pump, radiator and fan. The method of lubrication is identical and the carburetion and the ignition are as with the K-40 motor. The construction of the transmission system is the same save that the jackshaft is of the semi-floating type and the jackshafts are of vanadium steel, 1.375 inches diameter. The ends of the shafts fitting the differential gear are squared and the outer ends have flanges to which are bolted the driving sprockets. By removing either the top or bottom of the jackshaft housing the differential gear may be taken out. The semi-elliptic springs are 40 inches length and 2.25 inches width forward and 44 inches length and 2.5 inches width at the rear. The wheels are artillery type, 36 inches diameter and are fitted with 3.5-inch shoes forward and four-inch rear. The option is given of 38 by 5.5 pneumatic shoes with extra demountable rim at an additional price. The standard wheelbase is 120 inches with tread of 56 inches forward and 60 inches rear. The loading space of the regular chassis is 108 inches and with option this may be increased to 144 inches.

PIGGINS CLIMBS HEAVY GRADE.

Two-Ton Vehicle Withstands Governmental Test on Steep San Francisco Hills.

A Practical Piggins two-ton truck, made by the Piggins Motor Car Company, Racine, Wis., recently underwent a test at San Francisco, Cal., in the interests of the United States government. The car was loaded to its full capacity by the Inter-State Motors Company, local distributor of the Piggins, and the climax was reached when the machine climbed the California and Jones street hills without faltering.

FROM LATEX TO MOTOR TRUCK TIRES.

By J. E. Hale, Experimental Department, The Goodyear Tire & Rubber Company, Akron, O.

CENTURIES ago, long before the discovery of America by Columbus, rubber or caoutchouc was known to the South American Indian. As far back as 1500, Pincon, the Spanish explorer, told of these Indians of the dense forests bordering the banks of the great Amazon, who tapped the caoutchouc trees and extracted a milky fluid. He did not explain its use. Columbus noticed natives playing ball with a curious substance grown in the primeval forests and prepared according to native ways. Little did the Spanish explorer of the 16th century dream what an important part those immense forests were to play in 20th century commercialism.

Crude Rubber Received at the Goodyear Factory, Akron, O.—1, Ceylon Crepe; 2, Manihot Biscuit; 3, Soudan Stock; 4, Fine Para; 5, Ceylon Biscuits and Sheets; 6, Cameroon; 7, Massai Strings.

In 1770 Priestly, an Englishman, found that this milky white fluid, when hardened, could be used in effacing pencil marks, and in the early part of the 19th century Hancock discovered that caoutchouc could be used in the manufacture of articles of dress. A few years later Charles Mackintosh, a Scotchman, rendered two fabrics water proof by uniting them with a solution of rubber in coal naphtha, hence the name "mackintosh" for the water proof coat.

Not until about 1839, however, 16 years later than the advent of the mackintosh, did Charles Goodyear an American, discover the method of vulcanization and make rubber fit to take its place among the most important commercial products of the world.

The recent increase of rubber-tired vehicles, and the introduction and the development of the automobile for pleasure and the motor truck for commercial use, have increased enormously the market for crude rubber.

In 1898 the price of crude rubber, owing to the demand created, suddenly advanced. Some years before it had been foreseen that possibly the supply of South American gum would run out, and through the efforts of American and English planters, seeds were shipped to almost every tropical climate, and cultivated rubber trees were grown with success. The best rubber, however, still grows wild in the forests on the Amazon, and according to F. A. Seiberling, president of the Goodyear Tire & Rubber Company, Akron, O., who made an extended trip down the Amazon two years ago, the supply will more than equal the demand for some years to come. In the meantime rubber plantations are springing up in many tropical countries. Some of these are already large producers of high grade gum, and the future of the supply of raw material seems to be assured.

The number of tires manufactured annually for the commercial truck is increasing by leaps and bounds. Rubber men are certain the development of the truck industry in the next few years will be fully as spectacular as the development of the pleasure type of automobile has been in the past few years.

Rubber-producing trees, shrubs, etc., are found mostly in northern South America, Central America, Mexico, Central Africa and Borneo. The finest rubber obtained is fine Para, gathered in the Amazon regions of South America.

Selecting a rubber tree the natives cut V shaped grooves in the bark with a special knife made for the purpose, these grooves being cut in herring bone fash-

ion diagonally around the tree, with one main groove cut vertically down the centre like the main vein in a leaf. The latex of the tree, from which the rubber is taken, flows from these veins and down the centre vein into a little cup at the bottom of the main vein. When the cups are filled they are gathered, and brought into the rubber camp, and there the latex is coagulated by means of smoke. This is done by the use of a paddle, which is alternately dipped into a bowl of the latex and then revolved in the smoke from a wood or palm nut fire. This smoke seems to have a preservative effect on the rubber as well as drying it out and causing it to harden on the paddle, each successive layer of the latex causing the size of the rubber ball or biscuit to increase. When a biscuit of sufficient size has been coagulated thus, it is removed from the paddle and is ready for shipment to various countries where rubber products are manufactured.

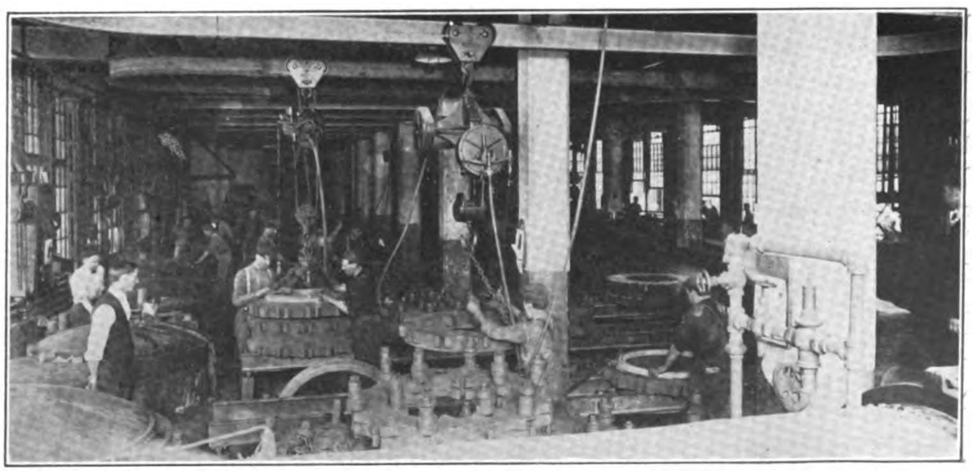
Crude rubber as it is received at the factory is more or less dirty. Sand, leaves and twigs sometimes constitute as high as 40 or 50 per cent. of the weight. These foreign substances are removed by washing the gum; one or two tons being soaked in warm water and then taken to a machine called a "cracker." The cracker consists of two large rolls covered with pyramidal projections which revolve very close together at different surface speeds. It is a powerful machine, and as the gum is fed between the rolls the projections tear it to pieces. During this process a continual flow of water from perforated pipes plays upon the rubber, and as it goes through these rolls repeatedly the water gradually washes away most of the foreign substances.

After this the gum is shovelled into boxes and taken to what is known as a "washer." This also consists of rolls, but the projections are relatively small and the rolls are nearer together. The work of removing the foreign matter is completed here, and in addition the gum is "sheeted out." Sheeting is accomplished by using warm water as the washing finishes. The heat is just enough to make the gum sticky so that from 15 to 25 pounds of rubber a sheet 18 inches wide, several feet long, and .1875-inch thick results. These sheets are then dried for from three to four weeks.

Mixing the crude rubber with the compounding ingredients is the next step. Each of the constituents of a 100-pound "batch," is carefully weighed and taken to the milling room. Here the rubber is warmed and softened before the compound is added, by passing it between the warm rolls of a machine similar in design to the washer, but much larger and with highly polished walls. The front roll revolves more slowly than the back one and the gum soon forms an envelope around this. The compound is sprinkled on the gum, a little at a time, and is gradually worked in by the constant kneading effect of the rolls on the softened gum. Finally the rolls are opened a little and the stock cut away in slabs about one-half inch thick.

Once again it is allowed to rest—this time 48 hours—when it is ready to be shaped for the rolls. In the case of rubber heels, pieces of suitable size are cut from the milled stock, but in making solid tires, where the length is many times the other dimensions it is necessary to make use of another machine. This is done by running through what is known as a tubing machine. This resembles a meat chopper on a large scale, with a die opening in place of the small holes. This turns out a continuous length of rubber of proper cross section as long as the milled stock is fed into the other end.

Then follows the weighing of each tire, cementing to the base band, laying in the mold, solting (or soap



Solid Tire Curing Room at Goodyear Plant, Where Truck Shoes Are Consolidated by Heat and Practically Completed.—Photo by Courtesy of Goodyear Tire & Rubber Company.

stoning) the mold, and placing the whole in a boiler heater where the heat for curing is supplied by steam.

The length of time required to "cure" or "vulcanize" a tire of medium size is about three hours. Taken from the heater it is cooled, removed from the mold, trimmed of the rinds at the line of contact of the halves of the mold, and the tire is ready for shipment.

Tire manufacturers have had to be chemists, inventors, analysts, and keen observers of conditions as well as mere craftsmen. They have had to establish their own precedents, to solve problems of construction and service that men have never faced before. It is a long step from the Amazon jungle, where natives slash trees and gather the sap, with chattering monkeys and brilliant parrots as an audience, to the sturdy rumbling truck that is revolutionizing traffic in the cities of the world.

Much study has gone into this fascinating phase of the development of a commercial age. Motor trucks are really locomotives. They run without permanent steel tracks (and are therefore practical) only because the rubber tree grown in the tropics, and its blood, congealed and compounded, finally makes a cushion for wheel rims thousands of miles away. Without rubber tires trucks could not succeed.

BALL BEARING THEORY AND PRACTISE.

Important Discussion on This Subject Prepared for Society of Automobile Engineers.

Franz J. Jarosch, M. E., a member of the Society of Automobile Engineers, has prepared for the metropolitan section of the society a series of discussions on the theory and practise of ball bearings, the first of which, under the title of "The Work of Balls and Ball Raceways in Radial and Thrust Ball Bearings with Respect to Friction and Load Relation," has been published in the S. A. E. Bulletin for November. The subject has been taken up with extreme care and different forms of journals, from plain to the separate ball type, are considered exhaustively, and the efficiency shown by admirable calculations.

The work is technical and contains a very large volume of information that is valuable to engineers, while there is no doubt of the quality of the ball bearing as compared with other types even to the casual or non-technical reader. It is seldom that a subject has been so thoroughly presented as has this, and it is illustrated with a series of drawings, each of which is clearly explained. As a contribution to engineering literature Mr. Jarosch may be praised for his work, for it is decidedly valuable and should be included in the library of every man who has to do with problems of transmitting energy or power. The address of the Society of Automobile Engineers is 1786 Broadway, New York City.

The Bosch Magneto Company, maker of Bosch magnetos, will have a special display at 223-225 West 46th street during the New York show.

NEW TRUCK WARRANTY.

National Association of Automobile Manufacturers Will Supply Blanks to Non-Members.

The new standard motor truck warranty adopted by the National Association of Automobile Manufacturers is ready for use. Handsomely lithographed copies are bound in book form, like bank check books, and these are available to non-members of the association, who desire to use the standard warranty in selling their product. The only changes made in the printed matter, in such instances, are in the name of the company, address and titles of officials signing the warranty, a sample of which appears below. Those desiring blanks should apply to H. W. Perry, secretary, commercial vehicle committee, N. A. A. M., 7 East 42nd street, New York City.

WARRANTY NO.——— TRUCK NO.———

This is to certify that we, the
SAMPLE MOTOR TRUCK COMPANY,
of Detroit

WARRANT the new motor trucks manufactured by us to be free from defects in material and workmanship, this warranty being limited to making good at our factory any part or parts thereof which shall, within ninety (90) days after delivery of the truck to the original purchaser, be returned to us with transportation charges prepaid, and which our examination shall disclose to our satisfaction to have been thus defective.

The warranty shall not apply to any truck which shall have been repaired or altered outside of our factory in any way so as, in our judgment, to affect its stability or reliability, nor to any truck which has been operated at a speed exceeding the factory rated speed, or loaded beyond the factory rated load capacity, or which has been the subject of other misuse, negligence or accident.

We make no warranty whatever in respect to tires, rims, ignition apparatus, lamps, gas tanks, signalling devices, generators, batteries or other trade accessories, inasmuch as they are usually warranted separately by their respective manufacturers.

The foregoing obligation to make good any defective parts returned as herein provided is in lieu of all other warranties expressed or implied, and of all other obligations or liabilities on our part, and we neither assume nor authorize any other person to assume for us any other liability in connection with the sale of our trucks.

It Witness Whereof the said Company has caused this Warranty to be signed by its duly authorized officers.

Dated........................, 19

MOTOR VS. EIGHT-MULE TEAM.

In Arizona Test Former Does Work in Ten Minutes, While Mules Take Seven Hours.

Recently a trial was made in the famous Fish creek between Phoenix and the Roosevelt dam, Arizona, to test the relative efficiency of the mule team and the motor truck. From the bottom to the top of the hill is 1.75 miles and the average grade is 10 per cent. It took an eight-mule team seven hours to haul a five-ton load up the grade. A motor vehicle took the same load up in 10 minutes.

A Federal truck, made by the Federal Motor Truck Company, Detroit, and fitted with a 20-passenger body, operates over this same road. It has been making daily runs for eight months between Phoenix and Roosevelt. Not once has the truck caused its owner any trouble. The latter is thinking of purchasing another Federal owing to the increase in his business.

50,000 TRUCKS OWNED IN UNITED STATES.

In a Few States Only Service and Pleasure Car Registration Is Segregated---900,000 Cars and 100,000 Motorcyles a Reasonable Figure---Actual Facts of Record.

MORE than one million motor vehicles are owned in the United States. This statement is not made upon estimate or without knowledge of actual conditions, and it may be stated that if motorcycles are included this figure will be considerably exceeded. The proportion of this number that is given over to business service is uncertain, but there is reason to believe that it will at least total 50,000.

To obtain the most definite information possible MOTOR TRUCK has secured the registration from every state official of jurisdiction save two, and has included in one instance the statement made by the manager of the leading commercial body of another state in which vehicle registration is not required by law.

To understand the true significance of the figures, which represent 37 of the 48 states, and the District of Columbia, it is necessary to point out that of a total registration of 970,427 motor vehicles of all kinds 56,710 are motorcycles, these being obtained from 22 states and one district. In 10 of the remaining 15 states from which statements have been secured, motorcycles are included with the general registration. It is extremely probable that the number of motorcycles included in the motor vehicle registration in the states of Delaware, Georgia, Indiana, Nebraska, Ohio, Tennessee, Washington, West Virginia and North Carolina, if separated, would materially affect the deductions that will be made.

The figures show in these 37 states a total of 200,204 pleasure vehicles that are registered as such, 17,679 service wagons that are so classified, 695,834 that include pleasure cars, commercial machines and motorcycles, and the 56,710 motorcycles. It is not the purpose to deal with the pleasurė machines other than to show the surprisingly large number in use.

In considering the motor vehicles owned in the United States it will be necessary to refer frequently to the following tabulation, and it will be noted that there are no entries for the states of Arizona, Colorado, Idaho, Kansas, Louisiana, Nevada, South Carolina, Texas or Wyoming, which either have no registration law, or merely local ordinances, and from Florida and Oklahoma, from which states no return was received:

State	Pleasure Cars	Service Wagons	Motor-cycles	Motor Vehicles Un-classified	Total Vehicle Regis-tration
Alabama	3,010	130	220	....	3,360
Arkansas	....	....	....	2,000	2,000

Total	200,204	17,679	56,710	695,834	970,427

The Motorized Traffic of New York City: The Stream of Pleasure and Public Service Machines Pouring North Through Fifth Avenue.—Photo Copyrighted by Underwood & Underwood, New York.

In the United States as referred to in this article the 48 states and the District of Columbia are included, and the District of Alaska and the island possessions are not considered, though the number of machines owned in them is perhaps worthy of consideration from the viewpoint of accuracy.

The registration in the instance of Utah is of Nov. 25, and in Massachusetts of Nov. 30, while in the other

states the dates range from Dec. 7 to 12, so it will be understood that the figures are distinct and dependable. To understand exactly what is comprehended by the registration laws would require a digest of each, but if there is any one thing noticeable it is the extreme variance of the requirements of the law. In Arkansas, California, Mississippi, New York and Utah it is not necessary to register motorcycles, but in Delaware, Georgia, Indiana, Kentucky, Nebraska, North Carolina, Ohio, Tennessee, Washington, West Virginia and Minnesota they are classified indiscriminately with the pleasure cars and the service wagons.

Of those states from which no figures are obtainable it is certain enough that a very large total is entirely reasonable. For instance, Kansas should more than equal the registration of Nebraska; Colorado should approach that of Rhode Island, at least; Louisiana will probably exceed that of Mississippi; South Carolina will no doubt reach that of North Carolina; Arizona, Nevada, Idaho, Oklahoma, Wyoming, Texas and Florida should equal the registrations of New Mexico; New Mexico, Montana, Kentucky, West Virginia, District of Columbia and Delaware, which should be compared in the order given. The total registration for the states taken as a basis of estimate is 76,815, and this will bring the total of vehicles for the nation to approximately 1,050,000.

Just a word about the registration requirements before dismissing the subject: In Arizona, Colorado, Idaho, Kansas, Louisiana, Montana, Nevada and Wyoming there is no provision for registration. Local ordinances exist in Colorado, Louisiana and Wyoming, but only in a few of the cities. It is obviously impossible to obtain figures from each community and all statements concerning registration in these states are without basis of actual data. The statement relative to Montana is supplied for the table by the manager of the Commercial Club of Helena, and is no doubt conservative. In South Carolina the registration is with the clerks of the county courts, and in Texas with the county clerks, and it would manifestly be impossible to obtain the facts save by reaching each official direct.

It will be noted that the statements do not specify the manufacturers and dealers in motor vehicles, and it would not be possible to supply this information without a digest of each law separately. In Massachusetts in the year of 1912 1114 manufacturers and dealers were licensed, and in Illinois during the same period 871, or a total of 1985 which does not appear in the aggregate. Not only this, some of the manufacturers and dealers have a number of machines operated under the same license number, and vehicles not in use need not be licensed, so it will be seen that the figures do not adequately represent the actual number of motor driven conveyances. As these licenses are generally granted annually it may be accepted that there are but few issued that do not represent a vehicle. While it is true that some machines have been registered in two states, these comprise a comparatively small part, and taking Massachusetts as an example, where last year 881 licenses were granted to non-residents (not included in the total of registration of that state), it will be seen that the percentage there is about 1.51, and the average will probably be not more than half of that figure. Oregon apparently has the best classification of its vehicles, which are divided into gasoline and electric pleasure cars, and the service machines are grouped as trucks, commercial cars, taxicabs and undertakers' hearses.

Considering the service vehicles, it will be noted that Alabama, Maine, Massachusetts, Maryland, Mississippi, Missouri, New York, Oregon and Rhode Island, with the estimate from Montana, have a total of 17,679, of which 9649 are in New York and 4036 are in Massachusetts. Missouri has 1301. It is but reasonable to believe that Arkansas, California, Connecticut, Delaware, District of Columbia, Georgia, Illinois, Indiana, Iowa, Kentucky, Michigan, Minnesota, New Hampshire, New Mexico, New Jersey, Nebraska, North Dakota, North Carolina, Pennsylvania, Ohio, South Dakota, Tennessee, Vermont, Virginia, Washington, West Virginia, Wisconsin and Utah, and which include all of the principal cities of the country aside from New York, Boston, Buffalo, Providence, Rochester, Syracuse, Albany and Troy, will at least have double the number of machines stated, so that 50,000 is well within the bounds of conservatism.

But assuming that this figure is definite, it will be seen that practically a fifth of the machines in use are in New York State, and this being so the possibilities of the market in all the other states must be apparent. It will not be denied that a large proportion of the motor vehicles is owned and operated in the cities, and it is no less certain that the use of both cars and wagons will become more general in the smaller cities and towns each year.

It may be well to regard the motor vehicle market for a moment from another aspect. Assuming that the total number of machines of all kinds in serviceable existence is 1,050,000, of which there are 50,000 service wagons and 100,000 motorcycles, this leaves about 900,000 pleasure cars, or about one to every 90 persons, assuming the population is 80,000,000. This would seem to indicate that there is a production of pleasure machines that will be adequate to meet all requirements with the normal facilities and resources of the industry. But with a very much greater number of service wagons needed for the haulage of the nation, and the demand increasing, the possibilities for supplying the market are far from adequate. This does not mean an appeal for expansion, but it does demonstrate the actual need of educating the people to the classes and types of machines that are suited for the innumerable purposes demanded by business requirements.

As an illustration of the possibilities for service machines one can contrast the 4000 vehicles of Massachusetts and the 3,000,000 population, or the 9500 wagons of New York with approximately 8,000,000 inhabitants of the state. Taking the number in Massachusetts and 80,000,000 population as a basis it

would be necessary to have 320,000 motor wagons to have the same ratio throughout the country. It is safe to assume that any person familiar with transportation in Massachusetts will admit there is yet but a small number of machines in that state when compared with animal conveyances. This being so it is well within the limitations of good judgment to affirm that the market has not even been prospected. Not only this, with the rapidity with which the people are acquiring knowledge of transportation it will require much more than the normal production of the industry as it now is to keep pace with the demands.

FEDERAL TRUCK IN DAIRY SERVICE.

ROBERT G. Miller, proprietor of the Highland Dairy, Bloomfield, Conn., has been using for the past few months a one-ton Federal four-cylinder gasoline truck with excellent economy. He expresses satisfaction with the machine and after an experience of two years says that the motor truck is far superior in his opinion to horses for milk delivery.

Mr. Miller asserts that under no circumstances would he resume the use of horses unless motors were not obtainable. He has learned by experience of motor truck efficiency and knows whereof he speaks. He now has 10 horses on his farm of 225 acres, but uses them for farm work only.

The one-ton Federal, Mr. Miller's second truck, has been driven about 7000 miles. The Miller dairy is about 6.5 miles from Hartford and the route for the most part is over good roads with few hills. The average daily mileage is about 25 miles.

From figures given it appears that the daily cost of operation is $3.50, to carry an average load of 1600 pounds. The car is used every day in the year, as Mr. Miller delivers milk seven days in the week. Just how the cost of $3.50 a day is established is explained at the end of this sketch.

Mr. Miller states that to do the same work with horses he would need four. Feed would cost 80 cents a day a horse or $3.20 for the four. Two horses would be used each day; that is, each pair would work alternate days, as it is considered too hard work to use them seven days in the week. Then, too, it must be considered that the horses might be incapacitated at times.

Mr. Miller supplies the restaurants of the Underwood Typewriting Company, the Pope Manufacturing Company, main and west works; the Royal Typewriter Company and the Hartford Golf Club. In addition to this he also delivers 150 quarts of milk (from house to house) daily. All his trade is west of Broad street, or approximately three-quarters of a mile from the centre of the city. Mr. Miller was asked how he happened to purchase a car and he stated that it was a case of buy a motor truck or go out of business.

The Federal is Mr. Miller's second car. He had a two-cylinder machine but this caught fire and was damaged so he disposed of it and bought the machine he now uses. Speaking of this first car, he states that it gave good service the 17 months it was used, but the pneumatic shoes were more expensive than he has found solid tires.

The Federal is also used in the open season for road work. With it men and supplies are transported from one place to another. During the past season Mr. Miller oiled 32 miles of road in the towns of Bloomfield and Granby.

Saves Three Hours a Day.

Just what the truck means to the owner is obvious when it is known that it saves three hours a day. It leaves the dairy at 7 in the morning and is back at noon. Using horses Dairyman Miller arose at 3 in the morning or thereabouts, left home at 4 and was delivering milk in Hartford at 5. "I have been peddling milk since 1893," said Mr. Miller, "and I have had my share of the hard work."

Federal Truck That Does the Work of Four Horses Regularly and Occasionally More, at a Cost of $3.50 a Day.

"Do you consider that the truck saves time?" he was asked.

"I save three hours a day and that means a lot in the planting and cultivating season. It also gives me a little more leisure and a chance to more fully enjoy life."

Many of the dairyman's neighbors, engaged in the milk trade, start three hours earlier and he is at home two hours before they return from the city.

The truck is used to good advantage for other work, but not for plowing, as the owner says he regards a traction engine more suited for such purpose. This autumn Mr. Miller transported 90 barrels of apples to Simsbury, over a mountain, where the apples were converted to cider and got the apple juice back

home in one afternoon after a day's work in the city. Mr. Miller also hauls his own coal.

The cost of operating the machine is as follows:

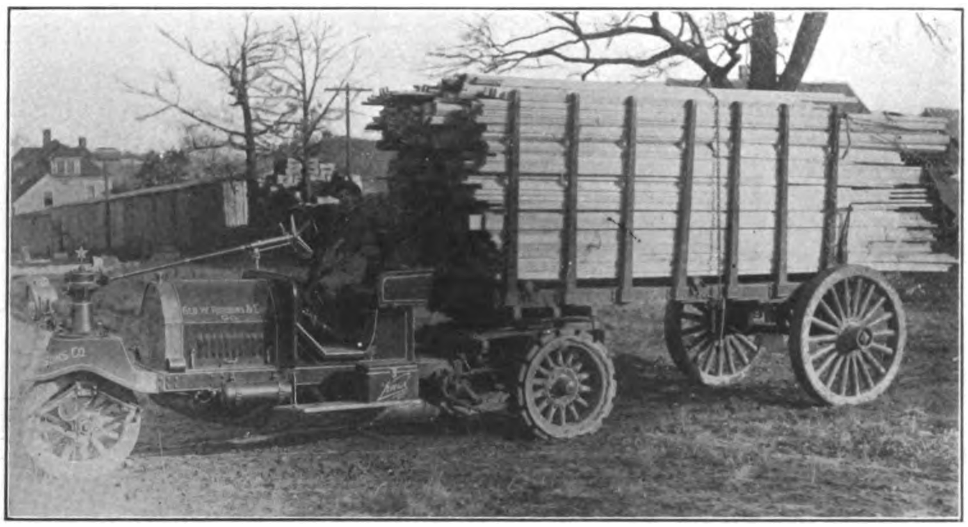
Interest of $1950 at 6 per cent	$117.00
Depreciation at $50 a month	600.00
Tires at one cent a mile, 12,000 miles	120.00
Gasoline and oil at 90 cents a day	328.50
Insurance	111.00
Total cost for year	$1276.50
Cost a day, 365 days to the year	$3.495

It will be noted that depreciation is charged off at $50 a month or $600 for the year. This is approximately 30.6 per cent., which is very high. To date the only expense has been 90 cents, 30 cents of which was for a half hour's labor in soldering a gasoline pipe, and 60 cents for an hour's labor in putting bolts on the sod pan. Mr. Miller states that an allowance of one cent a mile for tires is liberal. As the owner drives the car himself no charge is made for this usual item of expense which is about $2.50 daily.

MARTIN TRACTOR IN LUMBER HAULAGE.

While it is admitted by many lumber dealers that the motor truck is able to demonstrate an economy over horses in the haulage of this product, the chief difficulty lies in securing maximum efficiency. With the increased investment in equipment it becomes especially desirable to keep the truck at work as large a percentage of the time as is possible, particularly as there is no need for rest periods as with horses.

An accompanying illustration presents the Knox Martin tractor, made by the Knox Automobile Company, Springfield, Mass., and in service with the George W. Robbins Company of that city. Inasmuch as this concern has been using a two-ton Knox truck for the past two years and with considerable success, it will be conceded that its experience with both motor vehicles and horses has been such as to indicate the value of its opinion regarding the newer installation.



Knox Motor Tractor Utilized in Lumber Service with the George W. Robbins Company of Springfield, Mass.

This tractor is designed actually to take the place of the horses, the lumber being loaded on the ordinary horse wagon. It will be noted that the forward wheels have been replaced by the regulation motor truck road members attached to the rear of the tractor. While the latter is absent from the yard delivering the previous load, this forward portion of the wagon is rested upon wooden horses or some other similar arrangement, and the tractor backs under the load, is connected and is on its way again without perceptible loss of time. The Robbins Company uses its tractor in all sorts of service, including long hauls to Northampton, Palmer and Westfield, covering distances varying from 10 to 20 miles. It believes it has solved the loading and unloading problem effectually.

GOOD YEAR OF BUSINESS.

Merchant & Evans Company Reports Increase of 30 Per Cent. Over That of 1911.

In discussing the results obtained during 1912, Powell Evans, president of the Merchant & Evans Company, Philadelphia, maker of Hele-Shaw clutches, axles, transmissions, etc., reports that the volume of business done may be rated conservatively at 30 per cent. greater than in 1911. In some departments the increase was over 100 per cent. Concerning the matter of collections and losses, he says that the former are in excellent condition and the latter average less than in the previous year.

The various plants of the company have been taxed to their fullest capacity, and during a portion of the year time shifts were found imperative. Early in the year a site in the Wheeling-Pittsburg district was purchased, the idea being to secure the advantages of fuel, transportation and ideal manufacturing conditions. The dipping plant accordingly was removed from Philadelphia to Warwood, W. Va., just outside of Wheeling, and additions to the Philadelphia plant are now under way to take care of the greatly increased business in automobile parts.

The business for 1913 appears to Mr. Evans as most favorable. He adds that the company is prepared to fill all orders promptly, and that the plants in Philadelphia, Chicago and Warwood are all running full time. During January and February the removal and rearrangement of the Philadelphia works will not be permitted to interfere with spot deliveries.

LOCAL ACTION IN LEAD STORAGE BATTERIES.

By James M. Skinner.*

IN CHARGING storage batteries the current is obtained from a dynamo driven by a steam engine which receives steam from a boiler. Every effort is made to keep the boiler and engine and dynamo working at the highest efficiency. Perhaps mechanical stokers and feed water heaters and fuel economizers are used on the boilers, perhaps the steam lines are asbestos covered; surely the connections and stuffing boxes are kept tight, and dynamo brushes and commutator regularly inspected and attended to. All this to prevent loss of power—to save the coal pile. Power losses in a storage battery other than the normal watt-hour efficiency losses are very small. Nevertheless even small daily savings may add up to a considerable sum in a year's time, and when better battery service is added as an additional inducement, it may be worth while to consider how to eliminate even the small battery losses. These are the result of local action, a rather broad term covering several kinds of internal and therefore wasteful discharge. It will be the purpose in this paper to distinguish between the various kinds of local action, and their causes, and to outline certain simple precautions which will either entirely prevent them or will reduce their effects to a negligible minimum.

Local action may be divided into three very general classes:

1. Mechanical.
2. Chemical.
3. Electro-chemical.

The three types will be considered separately.

Mechanical Local Action.

Mechanical local action has no part in the normal working of a battery. It is the result of a short circuit between positive and negative plates in a cell. In rare cases this results from poor lead burning, a "run-down" from the positive group touching a portion of the negative group or vice versa. This, however, is the result of inexcusable carelessness, since a simple inspection of the groups after burning and assembling is sure to reveal it. A short circuit from a piece of lead dropped into a cell is in the same category. In some batteries short circuits occur, due to growth of the negative active material over the tops of the negative plates until it touches the lead apron separator hold-down on the positive group or bridges over the separator tops on to the adjacent positive plates. Such trouble, however, cannot occur on batteries made by the writer's company, because the negative material has little or no tendency to grow and because the separator hold-downs are of wood instead of being lead aprons attached to the straps.

In cases where a battery is abused by overheating trouble is sometimes experienced with the wood separators. Most battery owners, however, are careful not to overheat their batteries, and wood separators, which have been given a proper preliminary treatment, generally last the whole life of the battery.

Chemical Local Action.

Under the head of chemical local action will be considered here the effect of too strong sulphuric acid upon the capacity of a battery. A battery normally discharges by absorbing acid from the electrolyte, forming lead sulphate in the plates, and delivering over the external circuit an amount of current proportional to the amount of lead sulphate formed. In order that lead sulphate shall not form without the production of current the specific gravity of the electrolyte is limited to a maximum of 1.300 at full charge; 1.300 electrolyte contains about 40 per cent. of sulphuric acid. If the electrolyte contains more than 40 per cent. of sulphuric acid, that is, if its specific gravity is above 1.300, it will attack the negative plate, forming lead sulphate from the sponge lead, but in this case without the production of any current. In other words the battery discharges without doing any useful work. Moreover the strong acid is detrimental to the wood separators, and the lead sulphate formed is sometimes rather hard to reduce back to sponge lead.

The precaution against any such trouble is exceedingly simple—merely be sure never to add acid to a battery under normal conditions. It is never safe to add acid to a storage battery except upon the advice of a competent expert. No acid is ever lost during the normal working of a battery. The acid which was put in it when new is used over and over again. On each discharge it is absorbed by the plates; on each charge it is returned by the plates to the electrolyte. Unless some is spilled out, it is sufficient, without any replenishing, to serve during the whole life of the battery. After the battery has been charged several times it may seem as if acid has been lost, because the electrolyte level gradually falls. This fall is due to the loss of water by gassing and by natural evaporation, not to the loss of acid, and it should be compensated for by adding pure water only, once a week, more or less, never by adding acid.

Electro-Chemical Local Action.

Electro-chemical local action results from impurities in the electrolyte. Such impurities may be acids other than sulphuric acid, or metals other than lead. Neither has any place in a normal battery. Acid trouble is rather infrequent and there is no easy way for it to occur except through the introduction of hydrochloric acid in the form of common salt or salt water. If it will just be remembered that salt and salt water should not be allowed to get into a battery, the subject of acid impurities may be dismissed.

Metallic impurities are more common, but just as easy to avoid. They are of two classes. Some, such

*Engineer of the Philadelphia Storage Battery Company.

as iron, can exist in the electrolyte in two states of oxidation, and, by travelling between the positive and negative plates, being oxidized to the higher state of oxidation by the former and reduced again to the lower state of oxidation by the latter, can cause the formation of lead sulphate and consequent useless discharge of both positive and negative plates. A small amount of iron, given enough time to travel back and forth and to oxidize and reduce, can completely discharge the battery.

Other metals such as copper and platinum are not so active in travelling between positive and negative plates, but confine their attention more to discharging the negatives. As a battery cannot work with discharged negative plates, this is almost as bad as discharging both plates. During charge the impurities deposit on the negative plates in the metallic state. When the charge is stopped the deposited impurity forms with the sponge lead a little internal primary battery. A complete circuit being made by the conducting sponge lead, this little cell starts immediately to discharge. The copper (or other metal) dissolves and lead sulphate is formed in the sponge lead just as during a normal discharge of the battery, although in this case as in the other cases of local action cited, no useful work is performed.

Nothing but Purest Materials Used.

Reliable battery manufacturers are extremely careful to use nothing but the purest materials in the manufacture of their batteries. The writer's company, and undoubtedly some of the others, maintain extensive laboratories and employ trained chemists to do nothing but constantly supervise the purity of all materials entering into the construction of their batteries. They are absolutely sure that when a battery leaves their hands it is as free from impurities as it is possible to make it. To keep it in this condition it is necessary to observe practically only one simple precaution—use only pure water, preferably distilled, for maintaining the electrolyte level one-half inch over the plates Distilled water is safest because it is almost sure to be free from impurities. Natural water is sometimes safe and sometimes unsafe. It should not be used unless analyzed and reported on by the battery manufacturer from time to time. A very small amount of impurity in a sample of water is not a sufficient reason for assuming that the water is safe for battery filling, because although the water of each addition evaporates in, say, once a week, its impurities do not evaporate, but remain in the cell. The amount added in one filling may be small, but the accumulation of the impurities from several months' or a year's filling may be sufficient to cause a considerable amount of local action.

In conclusion, so that there may be no chance of a mountain being made of a molehill, it may be well to summarize the precautions which should be taken in order to practically eliminate local action. Two of them are negative—do not overheat and do not add acid, the last is positive--fill only with pure water, preferably distilled.

NOW WESTERN ELECTRIC-PITTSFIELD.

Two Well Known Electrical Concerns Form Alliance for Marketing Former Pittsfield Products.

An alliance between the Western Electric Company, New York City, and the Pittsfield Spark Coil Company, Dalton, Mass., about which rumors have been in circulation for some time, has been confirmed by both concerns. The Western Electric Company is one of the largest companies in the United States, doing an annual business of approximately $70,000,000, and its large engineering force will work in conjunction with the Pittsfield engineers in developing new apparatus.

Under the arrangement between the two companies the entire line of Pittsfield products, including magnetos, spark coils, spark plugs, timers and switches, are now to be marketed exclusively by the Western Electric Company, under the name of Western Electric-Pittsfield, although for a time the Pittsfield company will continue to market some magnetos direct. The sales efforts of the Western Electric Company will be directed largely toward manufacturers and supply houses. Ample stocks will be carried at each of the 28 Western Electric distributing houses located at shipping centres throughout the country. This brings the Western Electric-Pittsfield products within overnight shipment of every automobile manufacturer, dealer and owner.

LOCATES IN WASHINGTON, D. C.

American Motor Traffic Company to Produce and Operate Heavy Duty Vehicles.

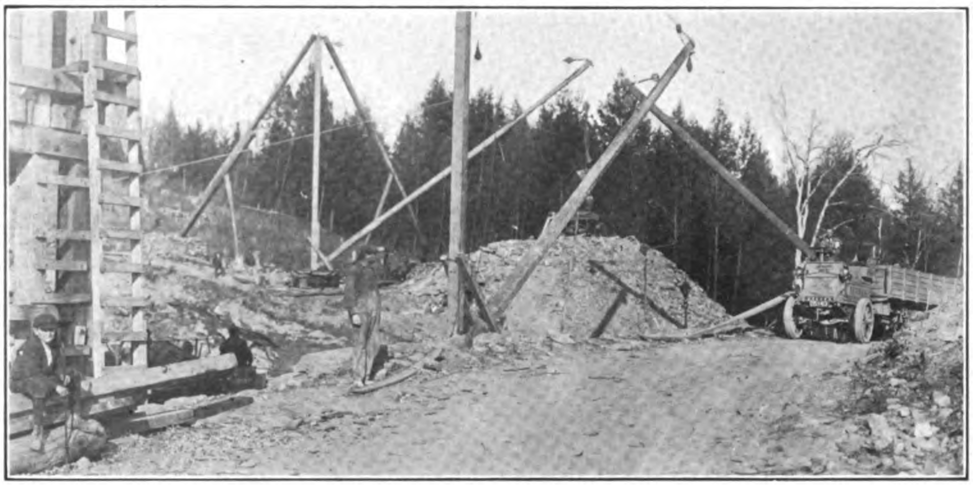
The American Motor Traffic Company, incorporated under the laws of South Dakota, was formally organized at Washington, D. C., where it will occupy the fourth floor of the new Citizens' bank building at 1421 G street, N. W. The directors of the company are: President, E. S. Alvord, president of the Littlefield & Alvord Express Company; first vice president and acting manager, S. J. MacFarren, manager of the Engineer Searching Company; second vice president, W. J. Moore, president of the Moore Company; secretary, A. L. Kley of New York City; J. C. Muncaster of Washington and J. C. Menocher of Pittsburg.

The company will specialize in heavy duty commercial motor vehicles of the pivoted spindle, multiwheel drive and steer type, with flexible load suspension and balance and also in liquid fuel combustion engines and vehicle accessories. Many other items of improvement in vehicle construction are controlled by the company under patents granted to Messrs. MacFarren, Thomas and others and further protected by special trade marks. The concern is empowered to operate as well as manufacture motor vehicles for all uses and proposes to establish freight, express and passenger services in response to demand, through its exclusive state agencies or auxiliary companies.

LOCOMOBILE TRUCK EQUAL OF 25 HORSES.

THE Bridgeport Hydraulic Company, Bridgeport, Conn., has demonstrated the practicality of motor trucks in construction work, such as is usually engaged in by contracting companies, and has found by comparisons made with animal service and conservatively estimated costs, that they are remarkably economical. The company owns the system of water supply for Bridgeport, the reservoirs, pumping stations and distributing mains, and the corporation is administered from a business point of view. The reservoirs are located outside of the city and to meet the consumption by the rapidly growing population a storage reservoir was projected at Easton, seven miles distant, on which work has been progressing the past year.

This basin is situated at a considerable height above the city and it is formed by the construction of a dam in a ravine. This dam is built with great strength and it is expected to endure for an extremely long period. Besides the dam, with the gates, sluiceway and outlets, the bottom of the reservoir is being so constructed that there will be a minimized loss of water through leakage. The work has been in accordance with the most advanced engineering and the requirements for material has necessitated the haulage of hundreds of tons from Bridgeport to the dam. As the most economical mechanical facilities and tools were used the same judgment that impelled their installation also considered the transportation of the materials and supplies. These included cement, machinery, pipe, tools, coal, lumber, etc.



One of the Two Locomobile Five-Ton Trucks Used by the Bridgewater Hydraulic Company, Bridgeport, Conn., That Takes the Place of 25 Horses in Construction Work.

The road from the railroad and shipping terminals at Bridgeport to the dam is across a number of hills, and is rough and at times extremely muddy and soft. The highway is not well surfaced in any part and the gradients are frequent and generally steep. The work was begun early in April and it was concluded to purchase two Locomobile five-ton machines, these to take the place of animals. Before purchasing the trucks the company made an effort to learn some accurate figures relative to horse haulage and made tests with coal carrying with a horse drawn cart. A four-horse team was used and hauling a four-ton load two round trips were made, a total of 28 miles, but it was evident that this work could not be continued if the animals were to be used every day. The cost of the team and cart was placed at $3.50 and the wage of the driver $2, this being a total of $5.50 a day, which is obviously extremely low, for very careful estimates have established $7 a day as a reasonably conservative figure. The ton-mileage was 56, when 40 is regarded as the maximum that could be expected from animal teams of this character. It will be seen that the cost accepted for animals was approximately 28 per cent. less than the average, and the horses did 40 per cent. more work than the normal maximum, so it will not be maintained that the standard by which comparison was made was in any way favorable to the machines.

The service conditions were such that to work horses regularly they should be driven two trips one day and one trip another, to prevent overworking them, which would materially reduce the load tonnage and mileage and decidedly increase the cost of transportation, taking the figures stated as the standard by which to determine efficiency and expense.

The trucks were worked on the basis of capacity loads and it was believed that four round trips was the maximum work, this giving a total of 56 miles daily, as against the two credited to the horses, and carrying a ton larger load each trip. But it was found after experience had been gained with loading and unloading and the road was better known that five round trips could be made without overworking the crew, giving 2.5 times the horse mileage and with a 25 per cent. larger load. But as a matter of fact the five trips represented 3.5 times the normal horse mileage.

The cost of operating the trucks was placed at $15 a day when four trips were made and $18 a day for five trips, and it was believed that these figures were very liberal and would leave a margin after providing for every item of expense. Considering the daily allowance of $5.50 for the horses for hauling coal 56 ton-miles the cost was placed at $0.1607 a mile, and allowing $15 as the expense for hauling coal 140 ton-miles the cost was fixed at $0.1071 a mile, or a difference of $0.0536 a mile. By this it will be seen that the truck did the work almost exactly 50 per cent. cheaper than the horses. But when the work for the five trips is considered it is found that the cost for carrying coal 175 ton-miles is $0.1029 or $0.0578 a mile less than

horses. Taking the truck cost as the basis of haulage the cost of the horse transportation is .561 more. This is a remarkable showing and were the extremely low horse cost considered it is probable that the saving would be not far from 100 per cent.

The following tabulation shows the facts as stated more graphically:

		Ton-Miles		Cost a Day		Cost a Ton-Mile	
Trips	Miles	Horses	Trucks	Horses	Trucks	Horses	Trucks
1	14	28	25	$5.50	$15		
2	28	56	70			$0.1607	
3	42	..	105				
4	56	..	140				$0.1071
5	70	..	175		$18		0.1029

Before the trucks were utilized the officials of the company were seriously considering the building of a road on a hill to reduce the grade, but after the machines had been driven for a short time this was found to be unnecessary. While no record appears of this fact, it is realized by the company that the trucks undoubtedly did save a considerable item of expense Had the use of horses continued this work would have undoubtedly been undertaken.

One of the officials of the company is credited with the statement that the trucks are actually taking the place of 25 two-horse teams. Besides this it is found that the trucks are not as destructive of roads as are horse carts fitted with narrow steel tires, and that the road traffic has been reduced, with the elimination of the delays necessitated for turning out for other vehicles. Neither is there the congestion, loading or unloading.

MURPHY LEAVES GENERAL MOTORS.

Will Establish Branch of Well Known Advertising Agency in Detroit.

Gleeson Murphy, for the past two years assistant to President Neal of General Motors Company, has opened a branch at Detroit for the H. K. McCann Company of New York, one of the strongest and best known advertising agencies in the United States. Mr. Murphy, who is a student of big organizations, leaves the General Motors Company with the asset of having materially assisted in the reorganization of that company and his purpose is to establish a complete advertising agency in Detroit, backed by the best experts in the merchandising line.

The McCann company is composed of general advertising experts of national reputation, including H. K. McCann, former advertising manager of the Standard Oil Company; Herbert W. Casson, well known writer, orator and efficiency expert; Thomas Nast, president of Nast art school; Gerald B. Wadsworth, author of "Principles and Practises of Advertising;" R. M. St. Hill, A. E. Foot and H. Atwood.

Mr. Murphy, besides having the advice of these men, will be assisted by a local corps of experienced writers and artists. He begins his new enterprise with a high degree of fitness for his work, his experience in handling large sales problems being a strong asset. The offices will be in the Boyer building, Detroit.

MORELAND FOR OIL TRANSPORTATION.

Special Loading and Unloading Device Aids in Handling Road Construction Materials.

One of the latest products of the factory of the Moreland Motor Truck Company, Los Angeles, Cal., is a five-ton chassis equipped with a 1500-gallon tank for the transportation of asphaltum and heavy oil for use in the construction of roads. The truck was constructed for the Brashror Burns Company, road building contractor, and was put in service recently by that concern.

A feature of the truck, the invention of Walter Moreland, is a compressed air device for loading and unloading the asphaltum and heavy oil. By this means much time is saved in the transportation of the oil and it is especially valuable in handling hot asphaltum. The truck was given severe tests previous to delivery.

WILL USE TRAILERS.

Lowell Transportation Company Adopts Plan for Increasing Efficiency of Its Garfords.

The Automobile Transportation Company, Lowell, Mass., a concern which does a large trucking business within a radius of 100 miles of that city, recently started three Garford five-ton trucks in its service. So successfully have they performed their tasks that the concern has ordered five more of the same make from the R. & L. Company, Boston, Garford distributor.

Trailers will be attached to these vehicles and on reaching Cambridge on the way to Boston, they will be left there to be unloaded and then reloaded, while the trucks will continue to Boston to deliver and load. Then on the return trip the trailers will be picked up at Cambridge and taken back over the road again, so that seven or eight tons will be carried by each machine.

NEW SWINEHART TIRE MANAGER.

Initial Step in Plan to Enlarge the Plant and Prepare for Increased Business.

Clifford B. Myers has been chosen general manager of the Swinehart Tire & Rubber Company, Akron, O., maker of Swinehart tires, to succeed W. W. Wuchter, president of the company, who has for some time acted in this capacity. The change is an initial move toward enlarging the plant and expanding the business generally.

The present plans take into consideration that in the near future the company will build a much larger factory than it now occupies. The site has not been selected, but as the present plant is is in the heart of the city with no vacant space in proximity, property probably will be purchased in the suburbs and eventually the old building will be sold.

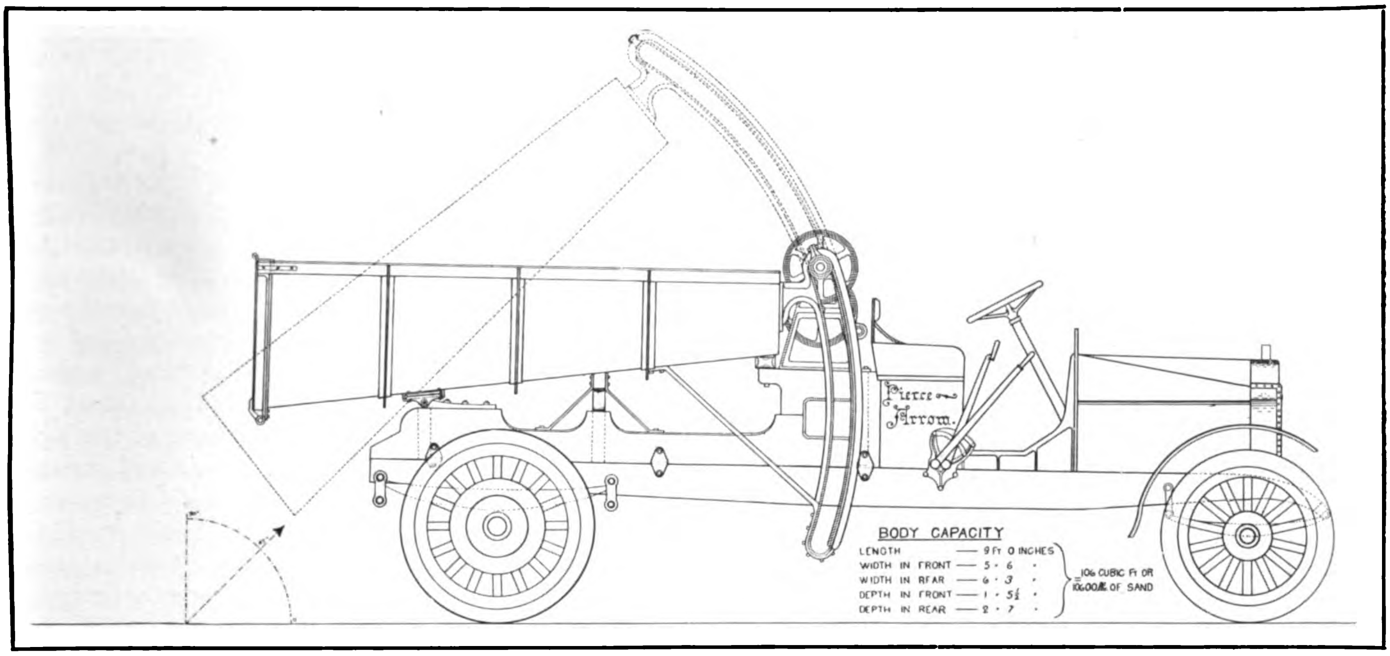
TIME SAVING TRUCK BODY EQUIPMENT.

Special Designs Created to Secure the Economical Loading and Unloading of Freight with Reference to Chassis Construction and Dimensions---Examples of Bodies Intended for General and Specific Haulage.

BODY building with animal service wagons was developed with reference to the use of standardized components. That is, the wheel manufacturers produced sizes of stock to meet actual demands, occasionally making special work to meet unusual requirements. The axles, springs, shafts, poles, etc., were similarly turned out. The principal reason for this was the economy resultant from the establishment of manufacturing on a commercial basis and to meet the competition naturally arising from different business interests active in the same market. Specialization was, as it is now, confined to the higher grades of work, but a very large number were disposed to use what might serve in a general way rather than pay the higher prices necessary in having equipment made to order.

The use of the motor vehicle has necessitated an entirely changed view of the requirements of highway transportation. There are many reasons why this should follow. The one is the general campaign of education for economy that has been developed by all motor wagon interests; the second is the fact that no two chassis manufacturers build with a view of standard body installations; the third, that loads are not carried with reference to distribution of weight on wheels; the fourth, that chassis are not selected with a view of adaptability to body equipment; the fifth, that many owners desire to use their vehicles for several purposes; the sixth, that mechanical features often demand construction that will afford accessibility and minimize the labor of attention and upkeep.

Chassis dimensions are generally determined by the character of the components used by the builder. If the differing elements, the power plant, the clutch, gearset, jackshaft or driving shaft, the radius rods, the axles and the steering gear, all of which must be considered in the length, are made by the manufacturer, he desires to maintain the sizes because his factory facilities must be kept within limitations. If he purchases some or all of his parts the proportions of these are quite as restricting. As material must be contracted for it is not practical to make changes to meet every demand. While it is true that some manufacturers make a number of sizes or types, changes are not made in chassis dimensions as frequently as in arrangement of the parts.



The Monahan Patent Steel Body, Designed for Haulage of Coal, Building and Construction Materials, with Manual Power Hoist.

Chassis length is far easier to adapt than chassis width. Though some of the builders make machines of the same capacity in differing lengths with a view of meeting the various requirements of purchasers, the width is not increased as a rule. Some of the larger machines have treads wider than the standard adopted for vehicles generally, 56 or 56.5 inches, but this does not mean that the chassis is increased in width. The difference is due practically to the wider tires and wheels, and the longer axles, but the distance between the side members of the frame is seldom if ever more than with smaller vehicles.

Then, under ordinary circumstances, it is necessary for the body to be constructed within the limitations of the chassis width. Lengthening is not a serious problem, but increasing the breadth is a subject

The Shadbolt Rear End Dumping Body for General Coal and Material Transportation, an Adaptation of the Animal Equipment.

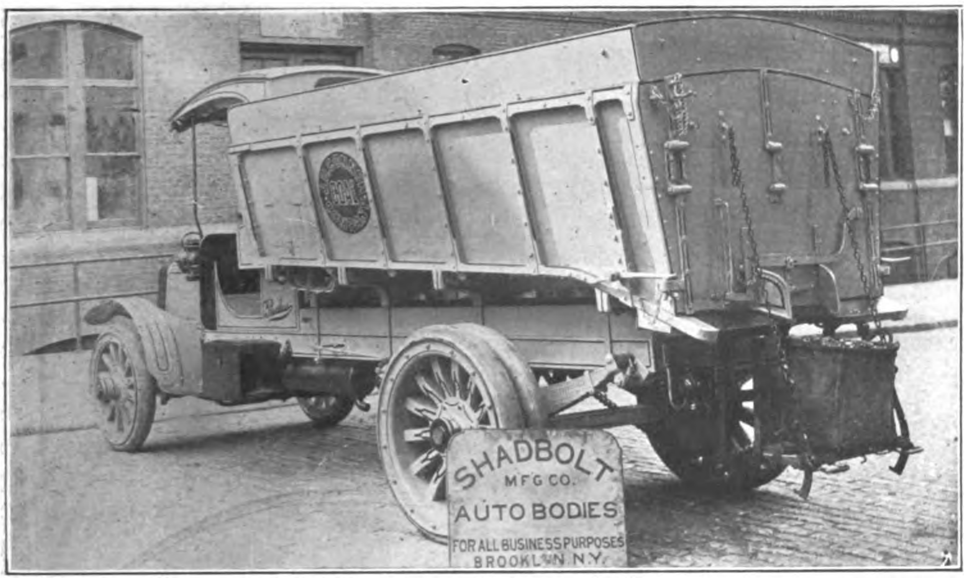
that requires the greatest care and study. The factors may be generally stated to be: First, the necessity of maintaining the centre of gravity as low as is practical; the second, the need of having sufficient elevation of the body to clear the wheels, no matter what the load; the third, the use of large wheels because of the better application of power and the greater economy of tires; the fourth, the character of the load to be carried; the fifth, the necessity of carrying the load as low as is possible; the sixth, the load distribution as required by the chassis design, and seventh, the practicability of insuring even loading.

It is not possible that these requirements will be met by installing bodies of stated dimensions on different chassis. Builders of chassis, especially those who had experience with pleasure car construction, first essayed to make the bodies desired by customers but it was quickly realized that to meet the extremely varied demands would require specialization instead of standard productions, and factory facilities to build whatever was wanted. This experience was repeated with others who have built wagon and truck chassis, and today the majority of machines are bought without bodies. The makers insist that the provisions of the guarantees given purchasers be observed so far as they can be and this is particularly applied to the installation of equipment, especially with reference to distribution of load.

While a number of chassis manufacturers will supply bodies adapted to some general uses, which include what may be regarded as recognized types, a few will sell only completed vehicles, making certain that whatever body is used it will conform to all the engineering requirements of the designs. There are other factors to be considered, however, and one of these is the forms of patent bodies now offered which can be obtained only from the builders, and which have certain advantages that recommend them to those engaged in differing forms of haulage. It would be idle to attempt to even outline the purposes of those who have invented bodies for general and special uses. While there is a limited demand for equipment for but one or several services and there are differing types that will serve the same purpose, it is obvious that the specialty is the more valuable from the fact that a higher price can be obtained, and today there are two classes of body builders—those having specialized products and those who manufacture the standard types of bodies only.

Aside from the problems to be considered with relation to chassis design and construction it is evident that there are other factors no less important—the handling of the loads. Theoretically it would be ideal to have freights so prepared for haulage and such facilities that loading and unloading could be performed in a very brief period of time. With animal vehicles endeavors were made to economize labor by carts and wagons with bodies constructed to be elevated by manual power, they being either balanced or raised by gearings or screw elevators, and discharging the contents by gravity, but time was not so much considered as was the work of the men, for the drivers were expected to at least drive and unload. Some excellent forms were designed for the haulage of coal, sand, gravel, brick and other materials, but no attention was given to loading other than filling carts by gravity from coal pockets and crushed stone bins. With wagons and carts used in construction work loads were frequently dumped through the bottom or from the sides.

The Shadbolt Rear End Dumping Body Drawn Back, as When Unloaded, the Winch and Chains Being Shown.



Rear End Gravity Discharge Coal Truck Body of Shadbolt Design, Adopted for Differing Classes of Use.

Equipping wagons and trucks with quick discharging bodies was merely another utilization of the devices that had been tried and tested on animal vehicles, and naturally enough these led to improvement and development. In the installation of these there is an element of cost that must be considered, and the question that is to be determined is whether or not there is a sufficient saving to justify the expense. By this is meant that if a specific work is to be provided for and a certain number of hauls can be made in a given period, unless the special equipment will save in unloading and loading the time required to make an additional haul, there is no economy. The only manner in which such a special body could be profitable would be in connection with increased speed that would make possible the carrying of an extra load. There would, of course, be lessened work for the driver and crew.

Bodies designed for a certain work are to be preferred to those that are not, although the cost is probably more, but with a builder's knowledge of requirements it is possible to obtain the fullest advantage of mechanical means for elevating and lowering the body, securing means for quickly unloading, and economizing the time of the crew. The manner of loading depends entirely upon the ingenuity of the owner. To illustrate, the use of platforms that will make possible the loading with a minimum of lifting, the use of conveyors, the use of derricks for lifting, the use of crates to prevent articles or material breaking and facilitating handling, the use of pockets or bins for gravity filling, the use of a sufficient area to prevent congestion and consequent loss of time when taking on freight, are all elements that are within his control. In meeting the requirements of those with special work to do the body builder has a problem that is often difficult to solve. If the loads are extremely heavy and not bulky a smaller equipment is advisable for many reasons, but if light and the load capacity of the vehicle is reached, then the matter of centre of gravity and the chassis stresses are to be considered. With the discharge of the loads gravity is largely depended upon, but this is augmented by mechanical means. Several bodies of the character referred to, which are exclusive productions, are examples of developments along practical lines, and have been perfected from knowledge born of actual service.

The first of these is a Pierce-Arrow truck chassis equipped with the Monahan patent dump body, built by the Monahan Vehicle Company, Providence, R. I., which is a steel construction carried on heavy wooden bolsters extending across the chassis frame. The body is built in sizes to carry any commodity or material and as proportioned in the accompanying drawing it has a capacity of five tons. The smallest size is for three tons and the largest thus far produced is eight tons. The purpose of the design is to afford a carrier that is adapted for coal, sand, concrete, gravel, brick, ice or lumber, and the body is built with reference to the weight of the material. For instance, sand will weigh 100 pounds to the cubic foot, and the body may be made with a capacity of 100 cubic feet, if for sand. In a similar manner the weight of any other material may be determined and the desired size of the body found. This, of course, applies to the maximum load.

Folding Shelf, a Feature of the Shadbolt Gravity Discharge Body, Raised to Permit the Helper to Take a Bag from It Without Stooping.

The Eureka Patent Dumping Body, Made by the Lally Commercial Body Company.

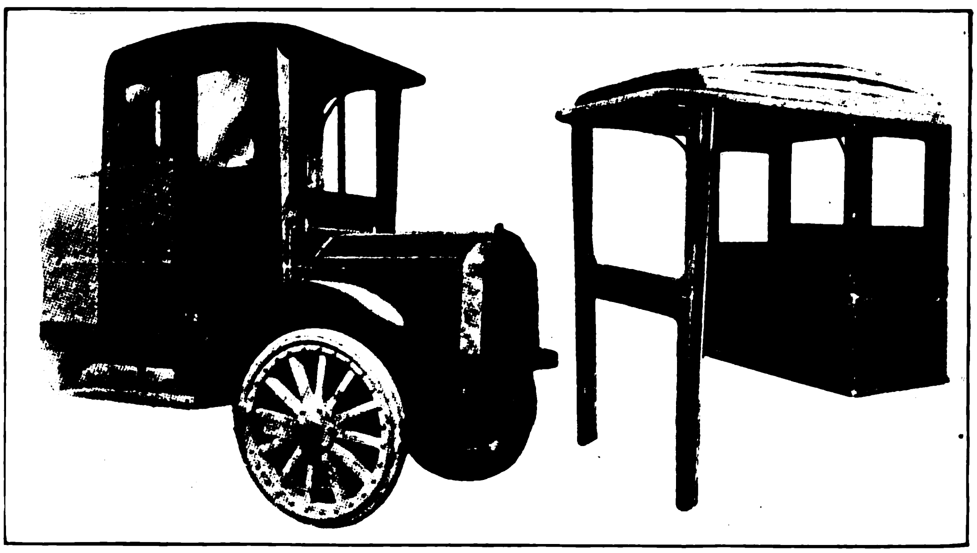
Considering this particular body, it may appear to be shallow, but it is nine feet in length, 66 inches width in front and 75 inches width at the rear, with depth of 17.5 inches at the front and 29 inches at the rear. Because of the overhang at the sides the body is raised to a height that will give ample clearance, and seen from the side the actual capacity is not apparent. With the Pierce-Arrow chassis the weight of the load is carried practically on the rear axle, and the body is carried on the two rear bolsters, which are nearly equidistant from the centre of the rear axles. On the rear bolster are the heavy forged hinges on which the body is moved. The bolsters are attached to the side rails of the cradle that is fitted and clipped to the chassis frame.

The body is constructed of steel plate and it has a frame of five T irons that support the bottom and sides, and the upper edge is strengthened by angle iron straps that are riveted to the T irons. The plates and the frame are hot riveted and the inside of the body is smooth and clear. The tail gate is hinged at the top on a stout round iron rod on which it swings on four hinges. On the bottom of the body are four forged eyes and in these eyes is mounted a heavy rod on which are forged four lugs. One end of the rod is bent at an angle of 90 degrees to form a crank or lever. This is connected with a lever that is held by an adjustable link. Releasing the lever and pulling it backward turns the rod and drops the lugs, and the tail gate is held in place by its weight. The gate may be lifted and dropped on the top of the sides if it is desired that the rear end shall be free.

The body is raised by a shaft carrying two pinions that mesh with two cast steel racks mounted at the forward end and stayed with heavy rods. The racks are in the radius of the lift of the body. The shaft is operated by a double compound series of gears which may be turned by a crank at either side. The body can be lifted to give an angle of 45 degrees inclination to the bottom, which is sufficient for unloading any load, even of concrete or asphalt. The body illustrated was built for a contractor and used largely for building roads. It is given whatever elevation is necessary for distributing the load, either gradually or at once. Two minutes is the longest time required to raise the body and five tons may be handled in that time by a man weighing 125 pounds, but one hand being required to turned the crank. The body is lowered by releasing the ratchet and holding a brake that will regulate the descent.

The Shadbolt Manufacturing Company, Brooklyn, N. Y., produces two bodies that are designed to save labor. The one is a dumping body, constructed of wood, that is mounted on a superstructure or frame that is clipped to the chassis side members. There is a slight inclination to the bottom of the body when ready for loading. On the sills of the body at either side, under the rear half, are heavy steel guides which take the ends of a stout rod extending through the side rails of the superstructure. These guides are formed at the forward ends to endure under a heavy strain. The body can be drawn forward or backward on the frame the length of the guides, chains being connected to a cross shaft carrying a gear at one end, into which meshes a pinion on a countershaft that can be operated by a hand crank. When lowered the body is secured by a latch that is operated by hand. When loaded the body can be unloaded by releasing the latch and drawing the body back on the frame until just past the centre of gravity, when it automatically tilts and the rear end of the body falls until it rests upon the ground. Then by reversing the movement of the hand crank the body is drawn back on the frame and automatically takes a position for loading.

These bodies are constructed of heavy wood frame.



The Star Cab and Storm Front Before Installation and When Ready for Use on a Truck.

panels and floor, and varying sizes, and are often fitted with flareboards to increase the capacity. The tail gate is designed so that it may be opened at top or bottom, or may be removed if desired.

Another body made by the same concern is designed especially for coal haulage. This is a wooden construction of heavy material and it is strongly strapped and braced. It has a rear end gate that may be elevated to any desired height. There is a slight inclination of the body bottom from the front to the rear, and this is increased considerably in angularity near the end gate. The inclined bottom will cause a movement of the coal as the load is removed. There is a small slide with wings at either side in the centre of the gate. The bottom projects for the length of the wings at the small opening, this forming a chute for unloading with bags or baskets. Mounted on the end of the body bottom is a shelf or bench, which is carried on a steel frame that may be adjusted for height, and it may be raised to the height of the body by drawing it straight backward. The shelf is folded against the frame when not in use. When unloading where the coal must be carried in the shelf is dropped. On this a bag or basket may be placed and filled by gravity discharge through the slide opening. Drawing it back will automatically lift the shelf and the bag or basket to a height whence it may be taken by the driver or helper without stooping, lessening the labor decidedly and preventing the coal scattering.

This body is not new, for it has been built for a number of years and in considerable numbers, but it serves a very useful purpose and economizes time and work. It has been used extensively in coal haulage in New York and vicinity. The company builds bodies that are fitted with side gravity discharge and are so constructed that partial loads of both hard and soft coal may be carried and either unloaded with equal celerity. A semi-trailer is another specialty with this firm, this having a capacity of 10 tons of stone, sand, etc., which may be used with a five-ton truck, and another trailer is used for hauling long lumber, and a body is built that is intended for transporting hot asphalt. The engineering department is now developing a demountable body for handling lumber.

The Eureka rear end dumping body, built by the Lally Commercial Body Company, Boston, is raised by manual power. It is mounted on a frame of oak sills and heavy bolsters attached to the chassis frame. This construction carries the load. The body proper has a frame of oak, consisting of sills, posts and top rail, with steel panels and reinforced steel bottom. The tail gate is designed to take out or swing as desired. In the tail gate is a scuttle door for gravity discharge into bags or baskets. The body is hinged on the rear bolster and hinged on the body is a steel frame that slides on two heavy steel members extending between the bolsters. The base of the swinging frame may be moved forward to lift the front end of the body, or backward to lower it, by compound gears and a hand crank. The body can be lifted to an angle of 45 degrees and held in any position by a pawl retained brake. One man can raise a five-ton load in five minutes, and the body may be lowered in five seconds. The construction is with special reference to endurance, all of the forging and fitting being of steel and unusually heavy. The body shown in the illustration, designed for a four-ton load, including all above the chassis, weighs approximately 2000 pounds.

The Acme dumping body, built by this firm, is mounted on a series of bolsters installed on a turntable. It may be raised by manual power to an angle of approximately 45 degrees and the load discharged by gravity from either side or at the rear. Where loads must be delivered in narrow streets and the truck must be drawn beside the sidewalk, gravity discharge may be obtained under practically all conditions.

The company has just perfected a body design that calls for a steel construction throughout. This body is so mounted on the chassis that it may be elevated to a height of nearly six feet at the rear end and to an angle that will permit a discharge by gravity into a chute that may be extended 30 feet across a lawn, over a fence or hedge, and reach a manhole or opening to a coal bin in a basement. The body is constructed so that a lift of the Eureka principle may be used. A five-ton load may be handled very quickly by one man.

The Star Storm Front Company, Troy, O., is building the Star non-racking auto truck top, with removable storm front, which is practically a cab that may be installed on any open truck or wagon, adapting it for use during the winter season. The cab consists of a top that extends over the dash, with sides and back. It is placed on the vehicle, taking the place of the regular seat. The rear window is permanently fixed, but the side windows drop into pockets in the side panels when desired. The storm front or shield is separate from the cab and consists of a frame that will reach from the dash to the front end of the bonnet or hood, with side members that are attached to the dash. A curtain containing two transparent panels fills the frame above the dash, and the open sides may be closed with curtains having one transparent panel each. These curtains are carried on automatic all-metal rollers when not in use. The windows will not admit water and are retained by springs. The entire construction is with a view of endurance and it is firmly secured. The storm front may be removed from the cab in a few minutes' time. The cab is completed with a generous box cushion.

H. H. Lundahl of Walnut Grove, Minn., uses his Reo truck, made by the Reo Motor Truck Company, Lansing, Mich., in hauling milk from his creamery to the railroad and between milking times it is doing the work of three teams about the farm. Recently a part of the land was to be fenced off and the truck carried several loads of fence posts of 256 posts each, many more than could have been carried on one horse drawn wagon. The interesting feature of the truck is the fact that during the service of over a year it has never been laid up for repairs.

EMPLOYS FIFTEEN VEHICLES.

New Haven Transportation Company Satisfactorily Solves Problems of Increasing Business.

The Smedley Company, New Haven, Conn., one of the largest transportation companies in Connecticut, has grown from a very small beginning and two years ago the business had reached such proportions that the transportation problems promised to be of particular annoyance. However, the motor truck was adopted as the solution and today with its fleet of 15 trucks, operating all through the New England states, the company has been enabled to maintain its immense service in an efficient and economical manner and has materially increased its business.

Besides nine small wagons which are used at New Haven for delivering parcels, trunks, etc., the Smedley Company has two 1.5-ton General Vehicle electrics, made by the General Vehicle Company, Long Island City, N. Y.; one 3.5-ton Kelly, made by the Kelly-Springfield Motor Truck Company, Springfield, O.; three Alcos of two, 3.5 and six tons, respectively, made by the American Locomotive Company, New York City. These trucks are constantly on the road, plying between Boston and New York. They have given invaluable service on long hauls and complete satisfaction with the equipment has been expressed by both owner and patron.

MOTOR TRUCK CLUB BREAKFAST.

Entertainment Planned for Industry's Leaders During Progress of Commercial Vehicle Show.

At a recent meeting of the Motor Truck Club of New York City, the following officers were elected: President, D. C. Fenner; vice president, Emerson Brooks; treasurer, C. E. Stone; secretary, E. L. Howland; board of managers, E. W. Curtis, Jr., George H. Duck, Karl L. Frederick, J. W. Perry, A. W. Robinson, W. Oscar Shadbolt and Arthur J. Slade. The selections were unanimous, there being no opposition ticket.

It was provided that no member shall be chosen for the office of president or vice president for two succeeding terms and that the terms be limited to one year. An entertainment in the form of a breakfast will be given to a number of leading men in the industry Jan. 21, during the week of the commercial vehicle show, when an attendance of more than 200 is declared to be assured. Permanent quarters have been taken at George Rector's, 1845 Broadway, and the Motor Truck Club Bulletin, the monthly publication of the organization, has made its initial appearance among the members.

RUSSIA BUYS MORE WHITES.

Repeat Order Held to Be Sequel to Successful Competition in Last Summer's War Trials.

War in Europe has brought business to the White Company, maker of White trucks at Cleveland, O. Word arrived at the factory recently that the Russian government wanted 10 three-ton Whites for immediate delivery. This is held to be a sequel to the peaceful victory of the White last summer in a war department truck competition held in the Czar's dominion, in which nearly every important maker of power wagons in Europe was a contestant against the White Company's product.

Against this sort of competition the American machines won, because the five Whites that started and finished the 1800-mile test did so with no repairs or adjustments being necessary. Examination of working parts developed no wear of any kind. As a result of this, the five White trucks were promptly bought as they stood, that being the only purchase made as a result of the test. The recent order, however, shows in what esteem and confidence the White product is held by the Russian government.

BIG SPEEDOMETER CONCERNS MERGE.

Makers of Stewart and Warner Indicators Combine with Capital of $11,000,000.

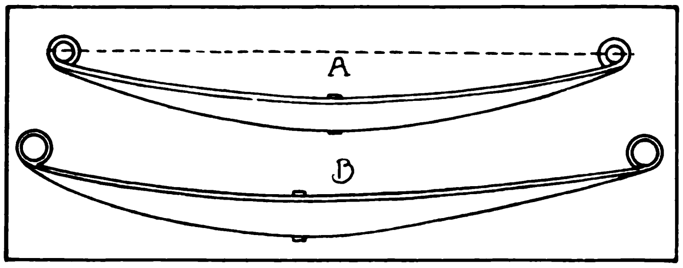
The Stewart-Warner Speedometer Corporation was recently organized under the laws of Virginia with a capital of $11,000,000, taking over the entire stock of the Stewart & Clark Manufacturing Company, Chicago, and the Warner Instrument Company, Beloit, Wis. The new concern will also acquire all of the speedometer patents owned by the Warner Instrument Company, A. P. Warner, C. H. Warner and J. K. Stewart.

The officers, directors and sales forces of the Stewart and Warner companies will remain as before and the product of each factory will be marketed separately. Whiteweld & Co., a New York and Chicago banking house, underwrote the proposition and financed the purchase. J. K. Stewart will be president and C. B. Smith, secretary and treasurer of the new company, the board of directors including representatives of the two old concerns and the banking house.

MOTOR TRUCK SPRINGS AND THEIR WORK.

Differing Designs and Constructions Standard with Vehicle Engineers—Effects of the Tractive Effort and Weight of Loads upon Suspension Members and Provisions for Protecting Them from Abnormal Strain and Wear.

NO PROBLEM that motor vehicle engineers have to deal with is of more importance than suspension. In fact it may be stated that the service and endurance to be obtained, in large measure, depends upon the design and quality of the springs used. It must not be assumed that the ideal has been reached, so far as design is concerned, as practically every form now used has been continued from wagon practise, but the quality of metal has been decidedly improved. Springs were first adapted to vehicles in England late in the first half of the 18th century and their use extended to continental Europe and America. Prior to that time carriage bodies were suspended on straps or links, and gravity was expected to compensate the shocks from inequalities of road surface.



Semi-Elliptic Spring: A with the Centre Bolt Normally Located; B, Centre Bolt Placed Forward of Usual Position, to Give Increased Wheelbase.

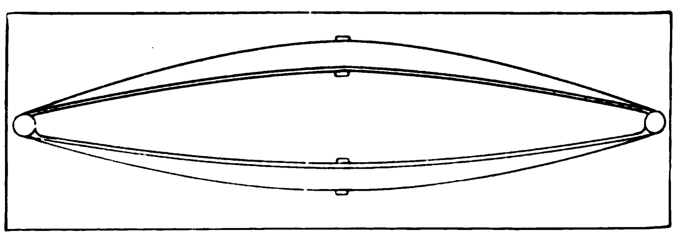
But whatever the form of springs used with animal vehicles two facts are certain: That the carriage or wagon was drawn and the relation of the axles maintained by perches or reaches so that there was comparatively little or no movement. When the first power carriages were built it was easiest for the builders to accept the suspension of the animal vehicle, because there was no experience with the requirements of automobiles or knowledge of the changed conditions that would be met with. It is practise today to follow the design of the construction of the wagon and carriage builders, although it is certain enough that there has not been the advance in suspension that would seem desirable.

There has been a change in the application of springs, this reference being to attaching them below instead of above the axle, but the perch or reach has been given over and radius or torsion rods have been used to preserve the position of the rear axles and the forward springs have been required to endure the stress of driving as well as suspension. In automobile practise A. L. Riker, now vice president and head of the engineering department of the Locomobile Company of America, appears to have been the only designer who gave attention to spring requirements, for he conceived a frame to connect the axles of his early electric carriages and wagons, which was flexible and would permit a vertical movement of both axles and minimize or equalize the driving stresses.

In the present day construction of motor vehicles the body is supported above the front axles by either semi or full elliptical springs. With the former design the "push" of the vehicle is transmitted through the chassis frame to the forward ends of the springs, and there the pivoted connection permits a movement of the spring on a bolt, while the spring pulls or drags the axle. With the latter form the upper half of the spring is connected at the centre to the chassis frame and the force of movement is exerted through the forward ends of both halves to the axle. The rear ends of both halves resist the stresses to a material extent and there is a driving strain proportionate to the distance between the axle and the chassis frame, governed by the speed at which the vehicle is driven. There is a different stress upon the full elliptic than upon the semi-elliptic spring when used on the forward axle of an automobile.

Semi-elliptic, three-quarters elliptic and full elliptic springs are used for rear suspension. When the semi-elliptic type is mounted with a bolt at the forward end, shackled to a spring horn at the rear end, the driving strain is upon the section ahead of the axle, for the rear end is free to move.

Sometimes the front and rear ends are shackled and the drive thrust is taken by the radius rod. When the three-quarter elliptic form is utilized and is similarly shackled at the rear and secured with a bolt at the forward end the driving stress is similarly upon the front half of the lower section. When the full elliptic spring is employed the strain is much the same as has been specified for the forward spring of this type. With pleasure vehicles the practise has usually been to have radius or torsion rods extending from the rear axle to the chassis frame or to the torsion tube housing the driving shaft. In the former instance the driving thrust is taken by the rods and the frame

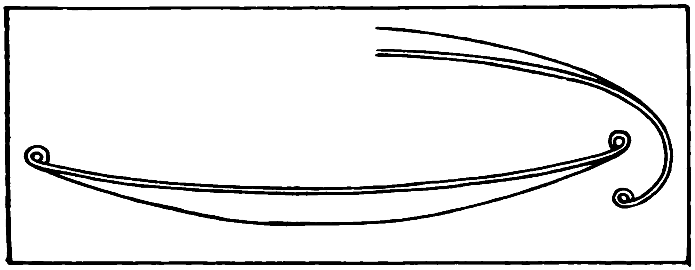


Common Type of Full Elliptic Spring, Generally Used on Light Vehicles.

and springs relieved, while with the latter the torsion tube may be connected with the cross frame member by a yoke, or the tube may be mounted by a globe and

socket secured to a cross member, so that the thrust is borne entirely by the frame.

With designs where the drive is by chains to a dead



Three-Quarters Scroll Elliptic Spring, a Type Not Used on Service Vehicles.

rear axle radius rods are usually installed between the rear axle and the ends of the jackshaft. There are variations of radius rod design and construction, but the principle is practically the same. In some instances these have connection permitting vertical movement of the axle, and in other both vertical and horizontal motion within certain limitations. Usually there is a provision for adjustment in the event of wear. The radius rods are expected to take the thrust of the traction wheels and where the propeller shaft is used, to prevent the thrust causing side pressure leverage on the gears and bearings. With the chain drive the purpose is to relieve the springs.

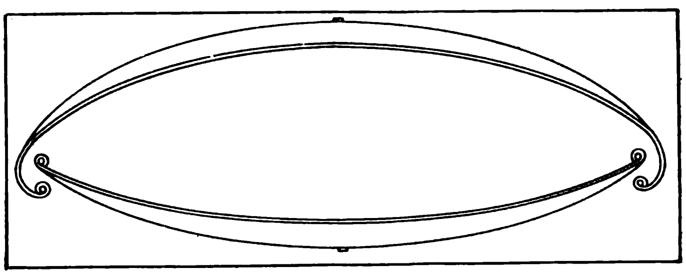
Where radius rods are installed on trucks one end of the spring, and often both ends, is shackled, this design eliminating the strain that would be caused by the forward and backward movement of the axles coincident with its vertical action, this motion resulting from the swinging of the radius rod from the centre of the point of attachment to the frame or jackshaft, and being backward as the spring is compressed and forward as it assumes its natural form. Obviously loading has a tendency to compress the springs and to force the axle backward, but the spring is not seriously affected, though it is not in its precise natural form when carrying the load. The difference, however, is not a matter for serious consideration. This change in the angle of inclination of the radius rod, from the vertical movement of the axle, does have an influence in tire wear, however, from the fact that it intensifies the stress upon the tire and changes the character of the stress with reference to the tractive effort.

In motor truck or wagon construction the drive thrust from the radius rods is taken by the frame, but the entire effort of propulsion forward is exerted upon the springs. It will be seen, however, with the drive transmitted directly to the frame or to the jackshaft, that there are shocks and stresses communicated that cannot be absorbed by the springs, and which the present forms of suspension will not compensate. That is to say, that what the springs would neutralize is taken by the radius rod and the frame and its entire assembly is more or less affected. There is a provision made in the design of the Velie trucks to minimize this effect by using a heavy helical spring that serves as a buffer at the forward end of the radius rods, but it is obvious that where the effects of flexible connection are secured, the advantages of rigidity are sacrificed. In the Eckhard truck design a long rod or tube, the forward end of which is fitted with a heavy buffer spring, connects the forward and rear axles, and this serves much the same purpose as a reach or perch in horse vehicle construction.

There is a turning movement of the rear axle, or at least a tendency of the axle to turn, from the tractive effort, and an opposite effect from the application of the brakes, which is also taken by the springs, and this cannot be compensated. In the Eckhard truck an arm is attached to the rear axle housing and from a cross member is suspended a heavy helical spring, and from this spring a chain is connected to the arm. Any extreme forward turning movement of the axle is checked by the chain and spring, and any shock is compensated to a considerable degree. This device is intended to serve only in the event of tractive effort, however. Reference has been made to these devices to illustrate that these effects have been realized by designers and endeavor has been made to protect the chassis and springs so far as this may be done.

The forward springs are always mounted under the chassis frame. The driving strain with the semi-elliptic form is primarily upon the eye or end of the spring, for the rear end is carried on a shackle, but with the full elliptic type the stress is upon the centre of the spring and upon both eyes. The top leaf of a semi-elliptic spring is known as the "master" and this carries the eyes, which may be formed by turning the ends upward and over, or downward and under, or forged solid. The first construction is regarded as the strongest of the first two, and the last probably the strongest and best. The leaf that extends nearly to the ends of the spring is known as the "long" leaf, and the lowest or smallest the "short" leaf.

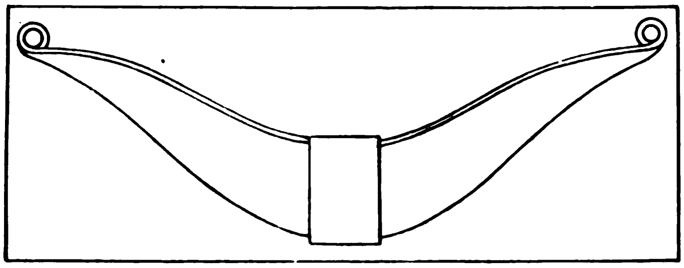
The design of the spring is of great importance, because this determines its efficiency. The type with a large number of thin leaves will be much more resilient than one with a few, and it will endure far longer, because there is not the same degree of stretching and contracting of the metallic fibres. The long spring will have relatively slower vibrations than will the short, and its action will be less violent. The long spring affords the easy riding qualities desired with pleasure



Full Scroll Elliptic Spring, Usually Adapted for Pleasure Motor Cars.

vehicles, and while this is also true of truck springs it is a fact that strength and not extreme resiliency is sought, so that there is not the shock absorbing qual-

ity in a heavy truck spring that would be expected of one designed for a pleasure car. For this reason there is greater vibratory stresses communicated to the



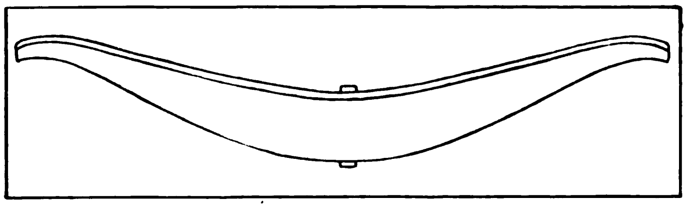
Heavy Semi-Elliptic Spring, Suited for Truck Construction, This Design Having What Is Known as the "Double Sweep" Instead of a Regular Curve.

frame and the components that are mounted in it.

Spring material is usually a specially prepared metal, because it is expected to have unusual elasticity. There is necessarily a limit to the life of metal, but this depends largely upon the elements composing it. The steel formerly used for springs contained perhaps .50 to .75 per cent. of carbon, this combination increasing the tensile strength and giving it an elasticity, but the tensile strength is increased more than the elasticity. Manganese steel has increased tensile strength as compared with carbon steel and is less brittle and less susceptible to crystallization, up to a proportion of about 1 per cent., but a greater volume increases the brittleness until about 10 per cent. or higher percentage is reached, when the metal becomes extremely tough and loses its brittle property.

Nickel steel is generally made with about 3.5 per cent. of nickel in its composition, and this may be regarded as the standard for general purposes. This metal has great wearing qualities and it has great strength and lacks the brittleness of carbon steel of the same strength. Until a few years ago it was used for practically all the purposes for which alloy steels are now utilized. Chrome nickel steel has the qualities of hardness and toughness, being especially adapted for gears and shafts.

Vanadium steel is a combination of vanadium with steel, the general average being .15 to .20 per cent. vanadium. The metal has great toughness, the action of the vanadium being to scavenge the steel of all slags, gases and blow holes that would lessen its value. It may be said that the vanadium purifies the steel and eliminates what would lessen its strength and endurance. Chrome vanadium steel differs from the

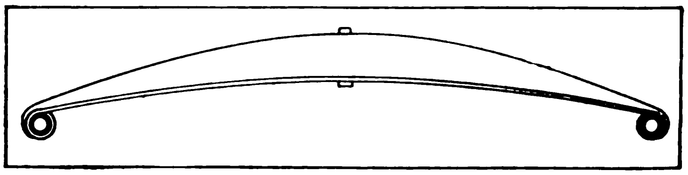


"Double Sweep" Curve Spring as Shaped When Carrying a Load.

vanadium product in that it is harder and has qualities that especially adapt it for many severe requirements, and is much used for springs. Silico-manganese steel has been used for springs and this metal is claimed to have unusual elastic qualities and extreme endurance.

All of these metals, to possess the highest qualities of strength and elasticity, must be "heat treated," which is the term used in the industry to designate what is generally known as "tempering.' In dealing with small parts and pieces of steel it is entirely practical to get every degree of "temper" by cooling or quenching in water and oil and by observation of the colors on a bright surface. But modern "tempering" means that the parts are "quenched" or cooled in water or oil and then heated to a predetermined degree in a furnace, the temperature of which is accurately measured. By this the metal is "drawn" at the point where it will have the required hardness and elasticity.

With springs there is always friction between the leaves proportionate to the work they have to do and their degree of elasticity. When straightened the leaves extend, and contract with the recoil, and no inconsiderable degree of effort is absorbed by this frictional contact. Spring leaves are retained when assembled by a centre bolt, by a special bead in the centre known as the "nib," by a bead that fits into a slot or groove in the plate above, or by lips that project at the sides near the ends and fit about the next longest leaf. These, save the centre bolt, are intended to



Semi-Elliptic Spring Designed for Use as a "Jack" or "Cross" Spring.

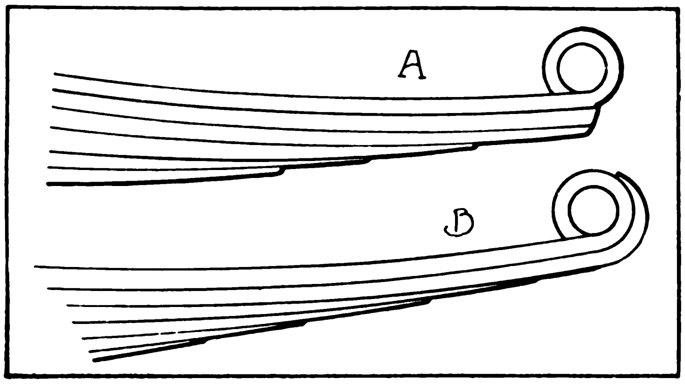
prevent a transverse movement of the leaves and maintain them in proper alignment.

The special value of alloy steel is better resistance against fatigue, or longer life, and increased endurance, but design is the principal factor that makes for ease in riding. When a spring is installed and a weight placed upon it the point at which it is at rest may be termed the load line. It will be deflected below this when the weight in the vehicle is increased, and this line will then become the load or stationary line. When a road obstruction is met the wheel and axle is forced upward and the deflection of the spring increased, or, if a depression should lessen the pressure for an instant the tendency of the spring is to resume the regular line of curvature.

A spring having a regular arc, as a semi-elliptic, is said in engineering phraseology to have a "true curve." If there should be a reverse in the curve, as is sometimes encountered in truck spring design, the spring is known as having a "double sweep." The type where the upper half curves below the lower half and connection is made with a shackle is known as the three-quarter scroll elliptic, as with a half section for the upper half, or a full scroll elliptic, as with a full section for the upper half. These are always used for rear installation with pleasure vehicles. The scroll

springs have usually greater curve than any other form.

The upper leaf of a spring always contains the eye,



Reinforced Springs: A, the Long Leaves Full Length to Support the Master Leaf; B, the Long Leaf "Wrapped" on the Eye of the Master Leaf.

that is, for a semi-elliptic or three-quarters form, and the driving effort is upon or through the upper leaf unless the eye is "wrapped" with the long leaf, or radius rods are used. It will be seen that this brings a strain upon the spring construction that is resisted largely by the clips by which the springs are secured to the axles.

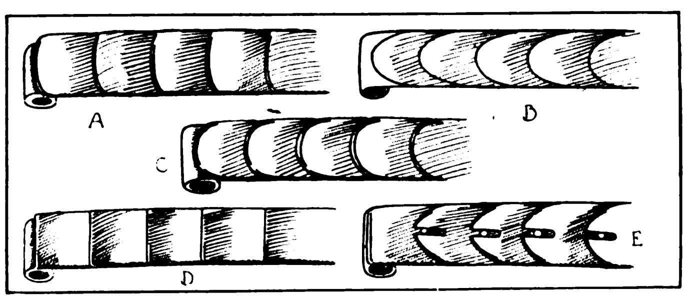
The thrust of driving the machine is always endured by the upper or master leaves of the semi-elliptic springs attached to the front axle, as the front eye is never shackled and is mounted in the spring horn or hanger. Not only this, but the road shocks upon the wheels must eventually be taken by the springs where they are fixed to the chassis frame. The movement of the springs is expected to compensate all the stresses, no matter how violent, and the degree of elasticity must necessarily be given by design, within certain limitations as to size. In design there are the several types stated, and these may vary in degree of arc or curve. In the design of springs the leaves or plates, except the master leaves, are usually thinner at the ends than in the centre, generally tapering gradually, and the ends of the plates may be finished in differing shapes. There is no rule or practise that governs spring plate end shapes. With heavy truck springs, however, the master leaf is often the same thickness of metal from end to end, and in this construction the long leaf is not tapered, so that the next or third leaf is the first tapering member, these two being full length. This gives a slow moving spring.

Springs are designed to have a certain form without load, ar. when loaded the form is changed in proportion to the weight. The effect of a wheel striking an obstruction is to raise it upward, and the spring is bent proportionately to the force. In ratio to the deflection is the reflection, which throws the body upward, and the tendency of the spring is to vibrate several times until the shock is absorbed. But the reflex action carries the wheels and axle upward, so there is not the same weight nor the same tractive effort for a very brief period. This brings another strain upon the spring. As the spring is deflected the pressure upon the leaves maintains their relation with each other to a considerable degree, but the reflection tends to separate the leaves, and to prevent this clips are often used that will permit a longitudinal movement, but will not allow separation. This affords a movement of the spring as a whole and prevents the master leaf enduring the full force of the reflex action. These clips are known as "clinch clips," used with light springs, with merely a sliding movement, and as "special clips," where a bolt or member is fitted with a sleeve, which had a revolving motion and lessens the friction.

The action of the spring that will result in wear is manifested generally at the eyes, and to prevent wear upon these points it is best to bush or line these with a metal that can be replaced when worn. Phosphor bronze, Tobin bronze and steel may be used, but the bronzes are preferred because of their anti-friction qualities, and with such bushings bolts hardened and ground are advised.

After springs have been used and exposed to water there is a probability of the surfaces of the plates in contact becoming rusted, which resists a free action and causes friction and wear. It is possible to introduce lubricant between the leaves by jacking the chassis frame to a point where the spring is relieved of pressure and the leaves slightly separate. Such lubrication is advisable at times and will result in much easier riding. Practically all spring bolts and shackles are now provided with grease cups, generally fitted to hollow bolts, so that the bearing and moving surfaces may be lubricated, and this provision minimizes wear. It is not possible to exclude abrasive substances from the eyes, however, and the best form of protection is to be certain that the bolts and eyes are effectively greased.

All springs are secured to the axles at what is undoubtedly the strongest section, but if a bolt is used to retain the leaves in assembly the members are rigidly maintained at that point and the movement must be at either side, with the strain most severe at the ends of the spring seat. The "nib" is another form of construction, but is not often used. If the spring seat is short the action of the spring is quicker and more pronounced, and the strain is concentrated, but if long



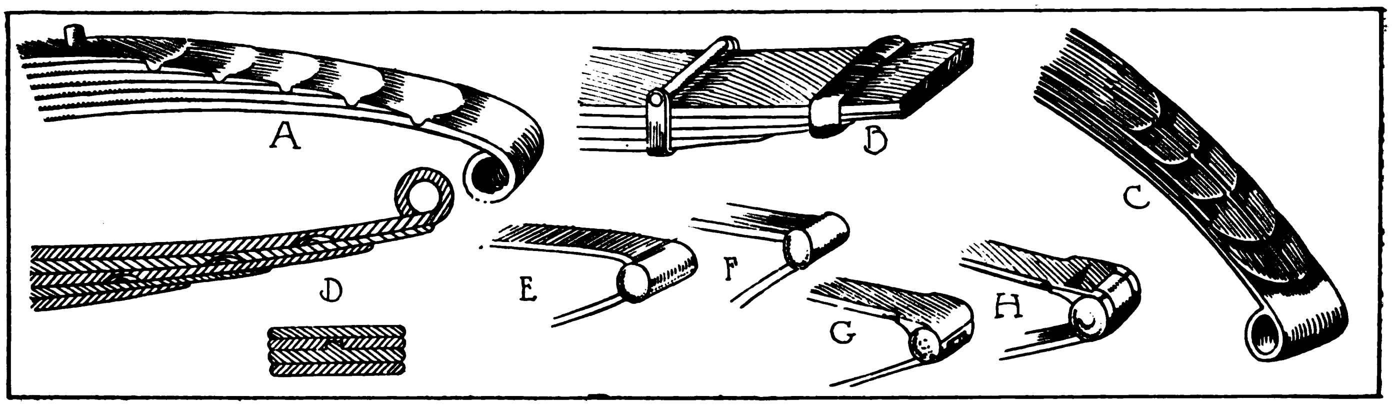
Spring Leaf Ends: A, "Special Round;" B, "Egg Shaped;" C, "Round;" D, "Square;" E, "Slot and Bead."

the action is slower and the spring is "stiff," but the stresses are more distributed. A very general practise is to fasten the springs to the axles by clips at

either side of the axle, with cross members passing under the axle connecting the two clips, secured by nuts. Sometimes a plate is used on top of the spring, through which four bolts are passed and two cross members similarly secured. The clips are usually made of a fine quality of Swedish iron to endure the extreme stresses. In several instances the axles have been drilled and a plate used that is secured as has been stated and by two bolts through the axle. This is not general practise, however.

With pleasure cars shock absorbers are very generally fitted, which resist the extreme movements of the springs and permit the action within limits that are determined by the owner or driver. These may be adjusted for either rough or smooth roads. Manufacturers of service wagons and trucks sometimes fit their machines with somewhat lighter rear springs than would be necessary to carry the full capacity and endure, and supplement these with jack or cross springs that are free and not utilized until a half load or more is carried. These may be in the form of a cross spring that is hung from a cross member, the ends of which contact with "pads" on the axles or incorporated with the spring clip plates, or auxiliary helical springs mounted between the spring clip plate and the chassis frame. The purpose of these is to make an easier "riding" vehicle with a light load and yet have sufficient capacity with a full freight. "Jack springs" are not an uncommon installation on differing sizes of vehicles. Such springs have different work than those which support the vehicle frame and are not subjected to the same stresses.

It will be seen that springs are designed to perform specified work and when a load is not equally distributed, as is frequently the case, there may be a much larger strain upon a spring than has been provided for in the design, and this will account for the "sagging" of springs. It may be noticed that springs will "sag" if required to endure a comparatively light load all the time, and obviously when overloaded service vehicle springs will become distorted. When distortion is noted it is possible to have a spring restored to efficiency by "tempering," which is a work often performed by blacksmiths, but this had best be done by an expert, preferably by the manufacturer.



Methods of Retaining Springs:. A, "Lipped" Spring; B, "Special" or "Roller" and "Clinch" Clips; C, "Ribbed" Spring; D, "Saw and Bead;" E, "Button Head;" F, "Berlin Head;" G, "Closed Open Head;" H, "Open Head."

BOSTON CLUB'S MEETING.

Feature Was Thomas A. Edison's Christmas Tribute to Frank J. Stone.

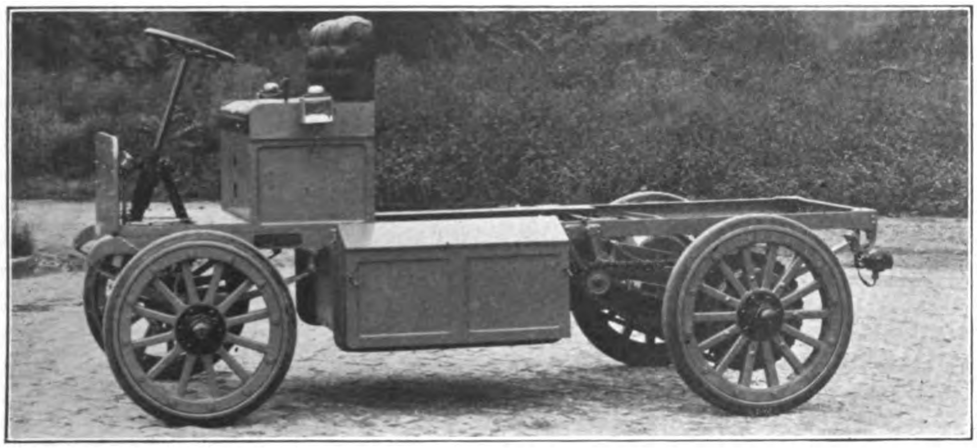
The Electric Motor Car Club of Boston, which includes in its membership the agents for and the dealers in electric pleasure and service vehicles of that city, at its December meeting, took occasion to make the most of the holiday spirit, and there was a Christmas tree from which gifts were distributed to the members, each being bestowed with an appropriate verse. The occasion was one of good fellowship and not the least significant incident was the presentation to Frank J. Stone, manager of the Boston branch of the Electric Storage Battery Company, of a portrait of Thomas A. Edison. Mr. Stone is widely known in the electrical world, and he is chairman of the committee on arbitration of the Electric Motor Car Club.

When it was proposed to present to Mr. Stone in a spirit of holiday merriment a printed picture of the head of a competing firm, and this fact was known to Mr. Edison, he said: "It would give me great pleasure to have Frank Stone know that I appreciate the great work he has done in the advancement of the electric vehicle, and to evidence this by sending him what I consider one of my best portraits, inscribed 'To Frank J. Stone, from Thomas A. Edison.'" The tribute of the great inventor to Mr. Stone's activity in his own field, and the expression of good will and friendship, was keenly realized by the members of the club, and Mr. Stone made appropriate acknowledgment of the gift and the sentiment that it represented.

O. B. Henderson, sales manager of the Baker Motor Vehicle Company, Cleveland, O., after a western trip that brought him in contact with a very large number of agents and representatives of the company, is very confident that the volume of business now in prospect will exceed that of any former year. Observation and information has convinced Mr. Henderson that there is a healthy tone to business and that there will be an extremely active market for both pleasure cars and service wagons. The company has made arrangements to produce a large number of machines.

ATLANTIC ELECTRIC VEHICLES.

THE Atlantic Vehicle Company, with general offices at 1600 Broadway, New York City, and factory at Newark, N. J., builder of Atlantic electric vehicles, devoted a long period of time to designing and developing a line of machines which the maker claims to be superior on design and workmanship to any product offered in the market. The vehicles, in capacities of 2000, 4000, 7000 and 10,000 pounds, are sold with the fullest knowledge of the possibilities for service and the company is confident that the claims made for these vehicles will be realized by the purchasers.



The Chassis of an Atlantic One-Ton Wagon, This Illustrating the General Design and Structural Characteristics.

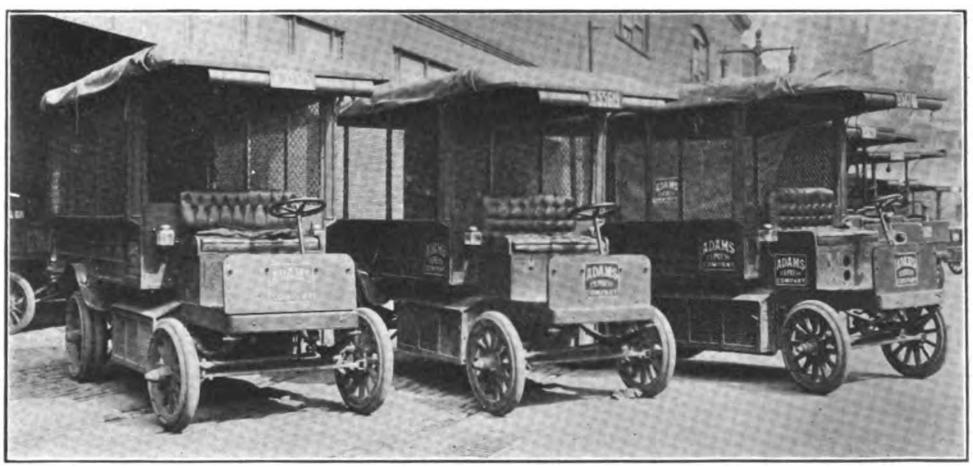
The machines were designed by Arthur J. Slade, the company's engineer, who is regarded as one of the foremost of his profession, who for seven years has made a special study of motor truck design and transportation requirements and needs. He was instructed by the company in undertaking the work to spare no effort in his department, that the machines should be of the highest quality, and it is maintained that the Atlantic chassis are the equal in quality of the very best of chassis for gasoline makes, having to a marked degree that simplicity of design that is to characterize the electric motor vehicle of the future.

In designing the Atlantic chassis it was believed best to have a standard and the different sizes are substantially the same, although they differ in the proportions of the components. No extremely radical or unusual features of design or construction have been incorporated in these vehicles, the purpose being to follow as closely as possible well established and standardized practise, making such improvement as experience had demonstrated it to be necessary or desirable in the proportion and size of parts, quality of material and workmanship. The machines have been designed and built with an ample factor of safety to insure against failure or undue wear for a long period of years when operated under normal service conditions.

The description given may be applied to any of the Atlantic vehicles, as it does not specify dimensions, but gives the general detail of the design.

The motor is built by the leading manufacturer of electric vehicle motors, and is the latest and most improved construction, having been developed with extreme care. It is a four-pole series wound type with a commutator of unusually large area, having low internal resistance and built to take temporary overloads as high as 300 per cent. The armature shaft, of large diameter, is mounted on annular ball bearings. The motor is enclosed in a dust and water tight steel housing, there being a cover that is almost instantly removable and which exposes the commutator. The motor is rigidly suspended by a crucible steel cross member with forged lugs, to which lugs the motor housing is bolted. This cross member is bolted to the chassis frame side members.

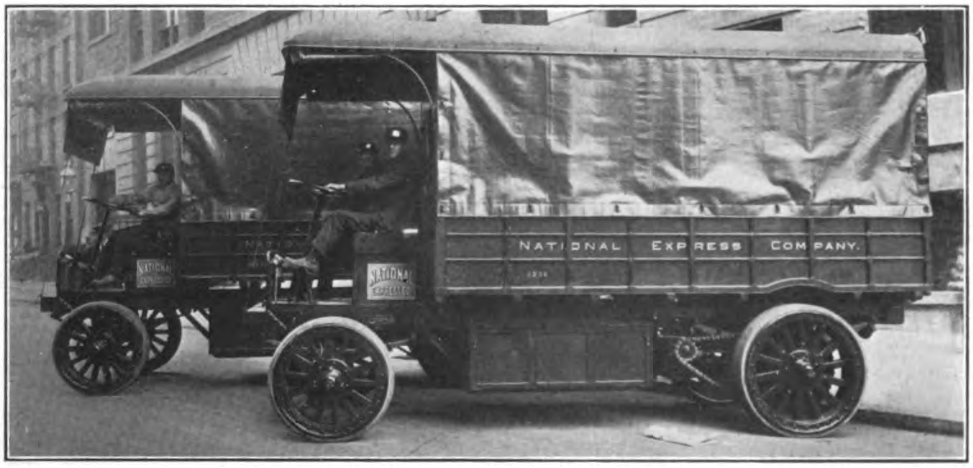
One end of the armature shaft of the motor projects through the housing, and on this is mounted a mild steel sprocket adapted for a silent chain. This chain affords the first reduction and drives the large mild steel sprocket mounted in the differential gear cage or assembly incorporated with the jackshaft. This chain is a Morse product, of wide cross section, and it is enclosed in a housing that is mounted at one end at the motor case and supported at the other by the jackshaft. The chain operates in this case in a bath of lubricant and it is extremely long lived.



Three Atlantic Two-Ton Wagons, Included in the Adams Express Company's Fleet in New York City Service.

The jackshaft is assembled as a unit and it may be

removed or installed as such with comparatively little labor. The differential assembly, of the bevel gear and pinion type, is contained in a cage or housing on which is mounted the differential sprocket. The differential gears and pinions are of 3.5 per cent. nickel steel, carefully heat treated. The differential gears are carried on annular ball bearings of very liberal proportions. The jackshafts are 3.5 per cent. nickel steel, heat treated and are mounted on annular ball bearings at the outboard ends. The jackshaft housing is Shelby steel tube, the inner ends of which are brazed into large malleable iron spiders, and these spiders are with heavy webbed arms that are assembled with large bolts. Integral with the sprocket on the jackshaft differential is a cast drum that is used for a brake. The spiders as assembled afford a support for the forward end of the chain case. The outer ends of the Shelby steel tube are brazed into crucible cast steel members which serve the threefold purpose of supporting the large annular ball bearings on which the shafts revolve, of enduring the thrust of the radius rods connected to them, and carrying the jackshaft.



Two 3.5-Ton Atlantic Trucks with the Standard Service Equipment, Used by the National Express Company.

Each member is bolted to the crucible steel castings that serve as hangers and are hot riveted to the side members of the chassis frame. These hangers support the front shackles of the rear springs. Four bolts support the jackshaft at either end, and by removing these the assembly may be removed from the chassis as a unit after detaching the chain case and loosening the chain.

The chassis frame is built of rolled steel channel section of generous width and depth, the weight and thickness being proportionate to the weight to be carrièd and the span that must support that weight. The members are hot riveted and are securely braced by large gussets. The frame is carried on semi-elliptic springs, constructed of material and proportioned to the demands. This detail has been given careful consideration, as the suspension of a vehicle is of vital importance, as the springs must not only be sufficient to endure under a normal load, but must withstand the road shocks and stresses to which they are subjected under widely differing conditions of operation. The springs must be flexible enough to minimize the vibration resultant from use that is transmitted to the chassis frame and all the moving and working parts, and absorb the shocks that would more or less affect the battery and the different elements of the vehicle. The tests made by the engineering department are claimed by the Atlantic company to have proved the design of the springs in use, and they are made of silico-manganese steel. This material is produced by the Krupp gun works at Essen, Germany, and is imported specially, the springs being made by one of the leading spring manufacturers of this country. The company claims that these springs are the highest priced used by any American truck manufacturer. The design requires a comparatively large number of thin and highly tempered leaves, affording extreme flexibility and great strength. The eyes are fitted with bronze bushings and the shackles are mounted on hardened and ground bolts of large size of a self-lubricating type.

The axles are drop forgings of a high quality of steel, which long experience has proven to be especially suited for the use made of it, the front axle being an I-section and the rear axle a rectangular form. The steering knuckles of the front axle are very heavy and the wheel spindles are large, being fitted with Timken roller bearings. The wheels are built to a design of the company by one of the best known manufacturers of the country. The spokes are rectangular in cross section, with ample support at the hub, and the large size spokes are "flared" at the outer ends, forming a shoulder that gives increased support of the felloe. The wheels are fitted with steel bands or rims that are shrunken on, and as the felloes and rims are made to the S. A. E. standards it is possible to have the wheel stock thoroughly seasoned and the wheels made in advance of requirements. As all of the tires made by leading manufacturers will fit these rims an owner has practically a choice of the products of the market. The wheels are built proportioned to the loads to be carried and take tires that meet with the requirements of the tire manufacturers, so that the owners receive the maximum guarantee of mileage with all shoes made by them. The diameter of the tires is liberal, especially with the large machines, for experience has demonstrated that tire expense with trucks is one of the principal items of operating expense. The front tires for the smaller sizes are 34 inches diameter and 36 rear, and for the larger machines 36 inches front and 40 rear.

The brakes are very carefully designed and have ample power to hold the vehicles under any condition of use. The regular service brake is incorporated in

the jackshaft assembly and it is a contracting band operating on the cast steel drum integral with the differential sprocket. The emergency brake has internal expanding shoes, which operate within the drums of pressed steel bolted to the rear wheels. These drums are large diameter and the brake is very powerful. The contracting band and the brake shoes are faced with anti-friction material and cannot be affected by oil, grease or any abrasive substance, and cannot be burned or destroyed by continual use. Both brakes are operated by pedals located near the base of the steering column, and may be used simultaneously if desired.

The drive from the jackshaft to the rear wheels is through the second reduction or side chains, of an amply proven and generally adopted type, these being driven over crucible cast steel sprockets, the wheel sprockets being bolted to the brake drums. The relation of the rear axle and the jackshaft is preserved by heavy crucible cast steel radius rods that have a radial movement at the rear axle, where bronze bushings are fitted to resist the wear. These bushings may be renewed whenever necessary. The rods are adjustable at the forward ends.

The steering gear is an irreversible worm type with unusually large wearing surfaces in contact, this construction minimizing the degree of wear and lessening the necessity of adjustment. The gear is mounted in a bracket attached to the chassis frame and has an inclination that conveniences handling. The tiebar and drag link, of large size, are carried above the axle and are protected by the axle and the projecting portion of the chassis frame.

The battery is carried in a cradle having a frame of substantial steel angles, with wood floor, sides and ends. The battery is installed at the sides, the panels being quickly removable and permitting the withdrawal of the crates for examination or work. The cradle is built to receive the type of battery selected by the purchaser, either acid or alkali forms, and these will vary with the form decided upon. The power wiring, from the battery to the controller and from the controller to the motor, is of cable of liberal carrying capacity, minimizing the drop in voltage to the lowest practical point, and thoroughly insulated against acid and weather influences. The wiring is well protected against all probable causes for wear or breakage. The controller is a continuous torque type, a product of the General Electric Company, and it has four forward speeds and two in reverse. The contact fingers are very liberal in cross section area of contact so as to endure and to insure long periods of service without renewal. It is possible, however, from the accessibility of the controller, to make such renewal a simple matter when necessary. The controller is operated by a pinion that moves a segment, through a handle projecting through the seat beside the driver, and the movement of the handle is comparatively small to pass from one extreme of action to the other. The controller is housed under the driver's seat.

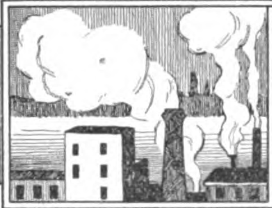
The drive is at the left side, the hand wheel being of large diameter to insure ease in handling under all conditions. The equipment includes a Sangamo ampere-hour meter, a main charging switch, a charging receptacle, two electric dash lamps, electric bell and a kit of tools.

An illustration of the care in designing is seen in the use of manganese steel, heat treated, in forged brake levers, brake shafts, levers, etc., insuring maximum strength and endurance, and in providing all wearing parts not otherwise lubricated with large compression grease cups.

The one-ton machine has a wheelbase of 102 inches and tread of 60, and a loading space of 101 by 60 inches. The normal speed light is 12 miles an hour, and 10 miles loaded. The two-ton wagon has a 114-inch wheelbase and 62-inch tread. The loading space is approximately 126 inches by 60. This vehicle has the same light and loaded speeds of the one-ton. The 3.5-ton truck has a wheelbase of 135 inches and 71-inch tread. The loading space is approximately 144 by 72 inches. The speed is 10 miles an hour light and eight miles loaded. The five-ton truck has a wheelbase of 144 inches and tread of 75, and the loading space is approximately 144 by 72 inches. The speed fixed is nine miles an hour light and seven miles loaded.

Atlantic Five-Ton Truck with Regular Body for Brewery Delivery and the Standard Cab Generally Used in This Service.

Officials of the Brooklyn Navy Yard recently purchased several Garford trucks made by the Garford Company, Elyria, O., which are in daily use handling sand, stone and other materials for pier and construction work in the yard, carrying coal for warships, etc.



BRIEF NEWS OF MANUFACTURER AND THE TRADE

The Van Winkle Motor Truck Company, Atlanta, Ga., has opened a city sales office at 39 Houston street. I. B. Lawton is manager.

The Beaver State Motor Company, recently incorporated to manufacture motor trucks at Portland, Ore., is planning the erection of a factory in the near future.

L. A. Bartlett has become identified with the Universal Motor Truck Company, Chicago, branch of the Universal Motor Truck Company, Detroit, maker of Universal trucks.

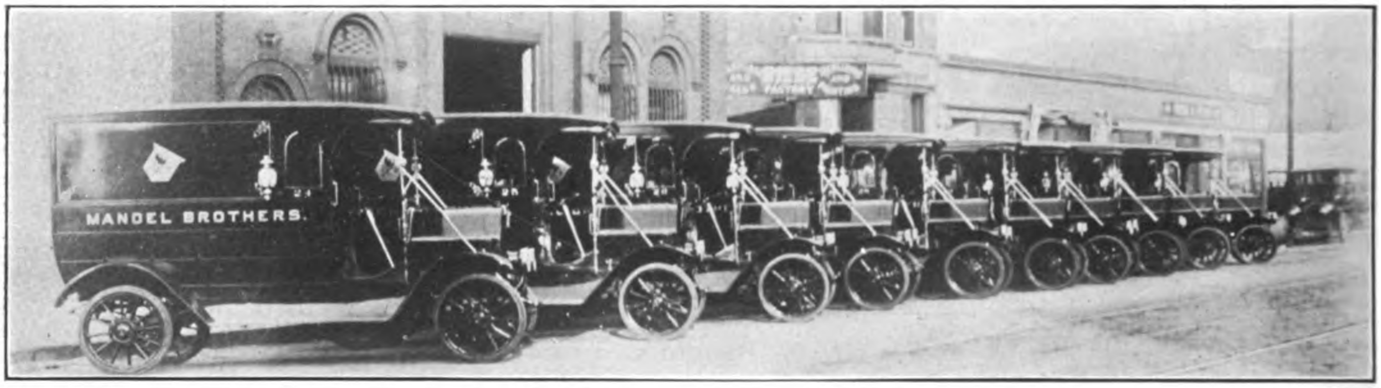
The Motz Tire & Rubber Company has established a branch in Boston, where Motz tires will be distributed. The new establishment is at 4 Dundee street and M. A. Frank is manager.

The I. Sekine Company, 530 Broadway, New York City, recently took the agency for Adams trucks, made by the Adams Bros. Company, Findlay, O., for the Island of Japan.

J. Perkins, for several years superintendent of the Saurer truck factory of the International Motor Company, at Plainfield, N. J., has resigned to become superintendent of the plant of the Rushmore Dynamo Works of Plainfield.

The Olsen & Juergens Company, Chicago, has just been formed to handle Lauth-Juergens trucks, made by the Lauth-Juergens Motor Car Company, Fremont, O. A service station has been opened at 905 West North avenue.

Mandel Bros., Chicago, Ill., has added 10 1000-pound Waverley electric wagons of the shaft driven type, made by the Waverley Company, Indianapolis, Ind., to its delivery service. Five of these vehicles are equipped with batteries capable of giving 60 miles on a charge, and the others have batteries capable of giving 75 to 100 miles. An accompanying illustration shows the new fleet, which was installed in time for the holiday rush.



Fleet of Waverley Electric Wagons Recently Added to the Delivery Equipment of Mandel Bros., Chicago.

P. W. Klinger, formerly connected with the Speedwell Motor Car Company, Dayton, O., maker of Speedwell pleasure cars and trucks, has been relieved of his duties as factory manager and has become chief engineer of the company.

Edward E. Hileman of Newcastle, Penn., has been appointed distributor for the Gramm-Bernstein line, made by the Gramm-Bernstein Company, Lima, O., for Newcastle and vicinity.

Frank B. Hutchinson, Jr., formerly of the Horseless Age and Motor staffs, has been appointed advertising manager for the Kelly-Springfield Motor Truck Company, Springfield, O., maker of Kelly trucks.

Warren T. Walker has been appointed manager of the Boston branch of the Kelly-Springfield Motor Truck Company. He was formerly the Boston representative of the Locomobile Company of America, Bridgeport, Conn., maker of the Locomobile cars.

The Piggins Motor Truck Company, Racine, Wis., maker of Piggins trucks, has established a branch in San Francisco, Cal., to serve as a distributing depot for the entire West, Hawaii and the Orient. J. I. McLaughlin is manager of the branch and will also distribute the Inter-State pleasure cars.

The Cass Motor Truck Company, Port Huron, Mich., maker of Cass trucks, has secured the services of E. J. Farkas, formerly chief engineer of the Cartercar Company, Pontiac, Mich., maker of Cartercars, as consulting engineer.

The Robinson Motor Truck Company, Minneapolis, Minn., has added a new model to its line. It is a four-cycle truck, to be known as the Minneapolis. The machine will be made in 1.5, two and three tons capacity. The company will continue to manufacture the Gopher, fitted with a two-cycle engine.

The General Vehicle Company, Long Island City, N. Y., has been incorporated under the New York laws with an authorized capital of $10,000,000 and will be known in the future as the General Vehicle Company, Inc. Two enlargements to the plant are being made at a cost of about $750,000.

The Chase Motor Truck Company, Syracuse, N. Y., maker of Chase trucks, has established a direct factory branch at Philadelphia. F. B. Porter, who has charge of the New York branch, also is in control of the Philadelphia establishment, which will serve territory in southern New Jersey, eastern Pennsylvania, Delaware, Maryland and the District of Columbia.

The Palmer-Meyer Motor Car Company, 5027 McKessock avenue, St. Louis, Mo., has announced a new 1500-pound truck, which has been thoroughly tested on the roughest roads in Missouri. It is proposed to manufacture 300 of these the first year.

The Standard Motor Truck Company, Detroit, Mich., has started deliveries on the new three-ton truck which the company will manufacture exclusively. While there will be but one chassis this will be made in lengths and with bodies to accommodate the particular line of business in which it is to be used.

The American Motor Fire Apparatus Company, Pittsburg, Penn., recently secured a charter in Dover, Del. The concern has a capital of $1,000,000. It will manufacture all kinds of machinery and motor trucks with fire fighting appliances. The incorporators are P. F. Bitbell, P. S. Chambers, Thomas L. P. Farr.

J. C. Ayres has been appointed manager of the Detroit branch of the General Motors Truck Company, erected at the corner of Lafayette avenue and Fort street. The service department is one of the largest truck garages in the country.

S. G. Chapman, San Francisco dealer for the Hudson cars, made by the Hudson Motor Car Company, Detroit, has taken the agency for the Stewart light delivery truck, made by the Stewart Motor Corporation, Buffalo, N. Y. The Chapman Company is erecting a new establishment which will contain the latest equipment for sales and service for both pleasure and commercial vehicles.

The Alco Pittsburg Sales Company, Pittsburg, Penn., has closed a contract with the Stewart Motor Corporation, Buffalo, N. Y., to handle the Stewart light delivery truck in Pittsburg and vicinity. The Alco Pittsburg concern is a strong organization and has a fine garage and service station.

L. B. Johns has been appointed New England manager of the General Motors Truck Company. He will have under his management the direct factory branch at Boston.

The
MOTOR TRUCK
Devoted to Motor Driven Business Vehicles of All Classes.

VOL. IV. PAWTUCKET, R. I., FEBRUARY, 1913 No. 2

MANY NEW TRUCKS AT NEW YORK SHOWS.

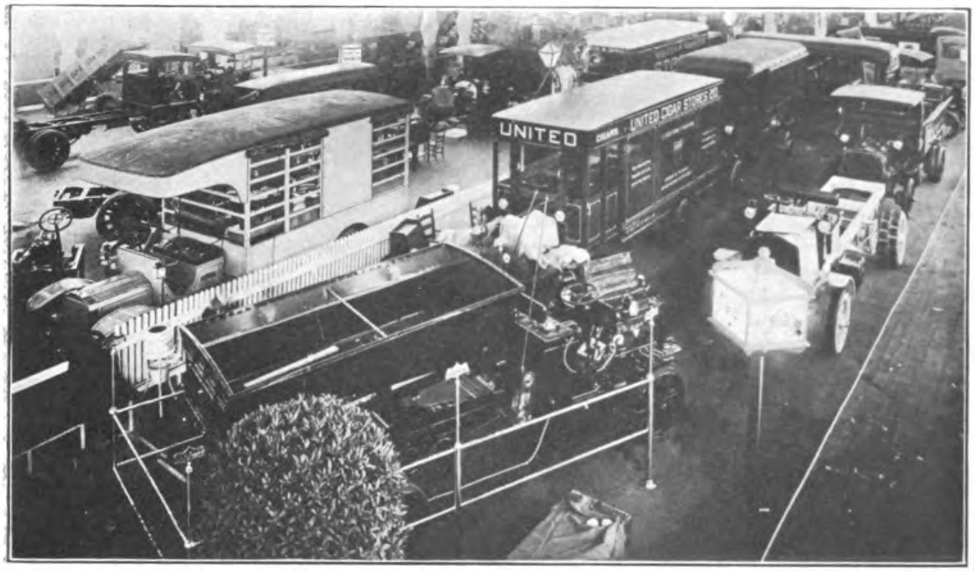
Worm and Concentric Gear Driven Machines Increase in Numbers and Special Attention Is Given to Body and Loading Equipment for Heavy Vehicles---Improved Brake and Spring Design and Heavier Constructions the Features.

NEVER in America was seen as interesting an exhibition of service wagons as that at Madison Square Garden and Grand Central Palace, New York City, from Jan. 20-25, and officially known as Part II of the opening national show of the year. The display attracted many thousands from outside of the city and brought together representatives of practically every concern of importance in the United States, and it was an attraction for engineers from the different factories and the mechanical experts of hundreds now using motor service machines or considering the advisability of using them.

There was a total of 62 exhibitors, but as one maker showed three different makes and another divided exhibits of electric and gasoline machines, there were really 65 separate displays, and the stands showed from one to seven machines. Were one to judge the success of the show from attendance alone the number of visitors might be regarded as disappointing, but when it is understood that comparatively few were attracted from curiosity, and business prompted the inquiries and investigation of those who entered either building, it may be said that the results were particularly gratifying.

Section of the Main Floor, Madison Square Garden, Looking from the Elevated Platform from the Madison Avenue End.

The number who attended the show with a view of making contract for agencies was surprisingly large, and the majority of the exhibitors had to give considerable time to consideration of propositions from those who are desirous of establishing desirable business connections. It is not exaggeration to state that from the agency making aspect the show was extremely productive, while there was a great deal of attention given by business men to examination of types suited to differing forms of haulage. The division of the exhibition between two buildings was in one sense a condition that might be criticised by some, and yet this was not without its benefits, for it influenced more general observation, instead of specific interest in several machines. Madison Square Garden was given over to the makers of wagons who had during the previous week shown pleasure vehicles, and while the number of exhibitors was smaller than at the other section of the show the majority of the exhibits were larger. At Grand Central Palace was seen the greater number of stands and the displays were often of those who had not shown the previous week. The show was opened at 8 in the evening of the first day, and at that time,



Service Wagon Exhibition, Madison Square Garden, Seen from the Elevated Platform from the Fourth Avenue End.

accessibility. There were new machines shown, and some of them admirable examples of engineering, but the majority of the developments of the year were to be seen at Grand Central Palace, where a number of western productions were exhibited for the first time.

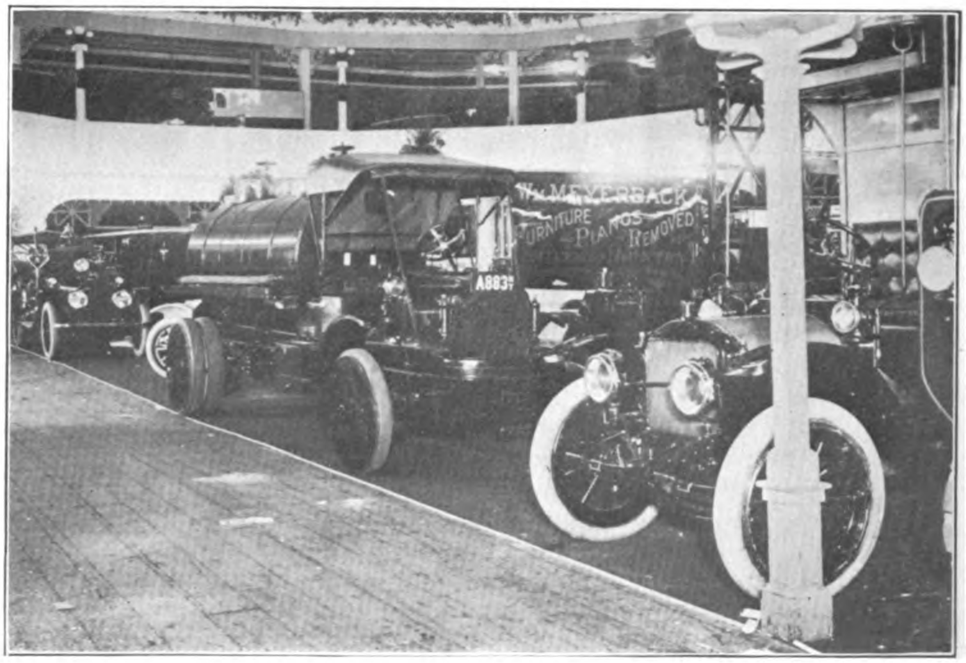
Too much cannot be said of the opportunity for the engineer or the expert to make comparisons of the different designs and types and to observe the constructions to meet needs developed by experience, for if there is one fact more than another emphasized by design it is the need of endurance and a continuance of service. The quality of design from an engineering aspect has become a very important factor, for the large concerns that have need of motor wagons believe that it is wise to depend upon the recommendations of their engineers instead of the judgment of the heads of departments who shall operate them, and this means that the vehicles are subjected to exceedingly careful examinations and judged upon their merits as understood by the men passing upon them. This was also a reason why the presence of capable representatives of the manufacturers, instead of salesmen in the usual sense of selling, played an important part in the results so far as sales were concerned.

While it may be true that personal knowledge of principles of construction may have weight with the man who is purchasing from a fund of engineering data, it is undeniably a fact that the recommendations are made without favor and largely upon the design,

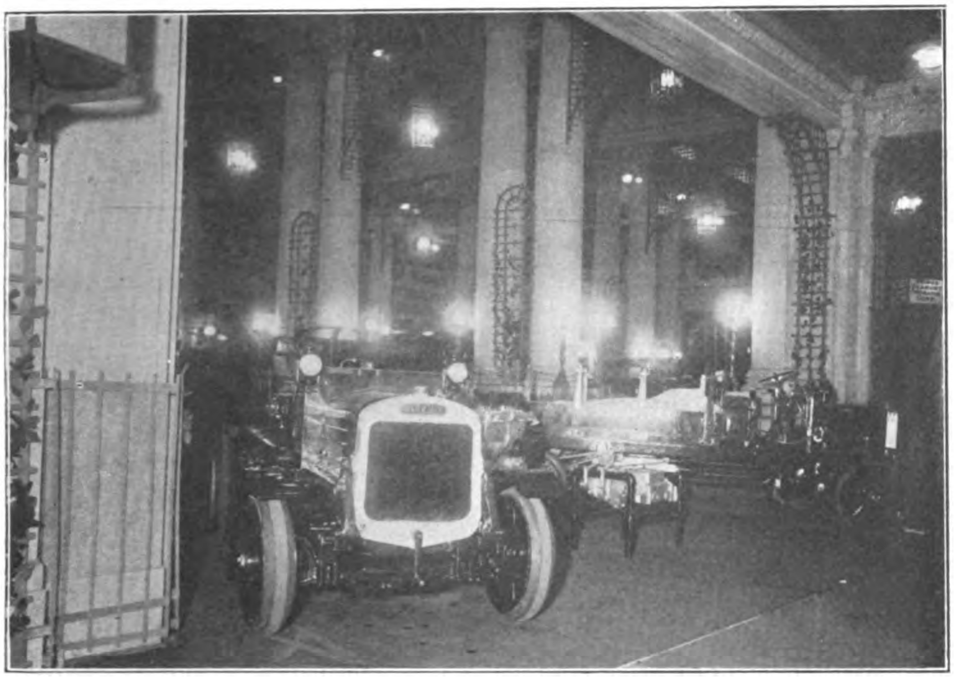
with one or two exceptions, the exhibits were in readiness. There were few changes from the announced list of exhibits. At Madison Square Garden the vehicles filled the main floor and the elevated platform, and the remainder of the space was given over to the accessory, equipment and supply displays, while at Grand Central Palace the main floor was devoted to machines and the third floor to other exhibits, the second or balcony floor, which had been utilized the previous week, being closed.

It is not to be assumed that the exhibitors aside from those who showed vehicles, were satisfied with the results the second week, because there were not the throngs that filled the buildings during the pleasure car show, and it is difficult to trace actual sales made through observation and demonstration. But it was the general belief that with keenly interested visitors there would be results that could not be otherwise than beneficial.

While the exhibitors at Madison Square Garden were chiefly the older and larger builders of wagons, the displays at Grand Central Palace were generally by those not as well known, while there were several who for the first time exhibited at a New York show. The Madison Square Garden displays were decidedly interesting and represented the best productions of the industry, but as a rule the progression evidenced was in perfecting designs that may be regarded as standard. That is, there was comparatively little change, and the endeavors of the designers had been to improve details and insure increased endurance and greater degree of



A Glimpse of the Main Floor of the Truck Show at Madison Square Garden.



Looking Across the Main Floor of Grand Central Palace from the 47th Street Side.

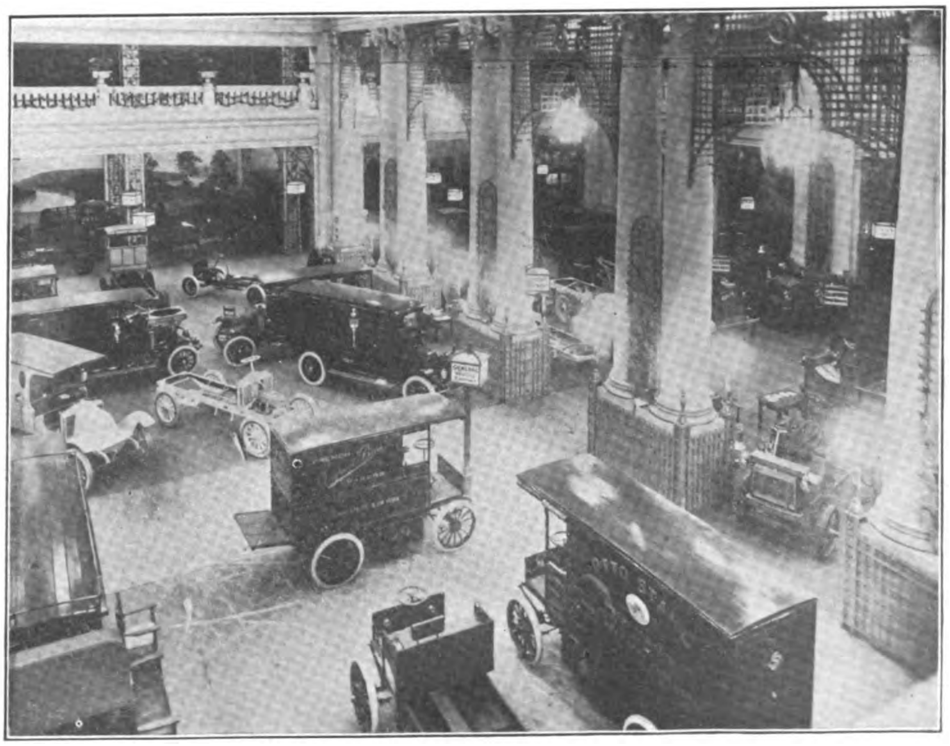
designs and constructions seen for the first time. All of the new electrics, however, were constructed along well defined lines and were in accord with well established principles.

There was undoubted interest manifested in the exhibits of worm driven machines, and there was a decided gain in the number shown, a demonstration that this form of power transmission has appealed strongly to manufacturers. The veteran of the worm drive is the Pierce-Arrow truck, and this year while this was the only vehicle so driven shown at Madison Square, at the other division was seen the Smith-Milwaukee, shown at Chicago in 1912; the Rowe, the Blair, the Universal and the Studebaker one-ton electric, and the Schacht, which was to be exhibited, was not so completed that it could be displayed. The Smith-Milwaukee 6.5-ton worm drive was the largest with this form of transmission shown. Next came the Pierce-Arrow and then the Rowe, Blair and Universal of the gasoline wagons. There was also a considerable gain shown by the users of the internal or concentric gear drive, these being the Mais, the Brown and the new Studebaker. There are three other makers using the internal gear drive and one other electric manufacturer has adopted the worm drive, so it will be seen there is a considerable group that has taken up these

material and workmanship being given equal consideration.

From a mechanical viewpoint the machines were especially interesting. There were few that had made no change whatever in the designs, and with a majority the detail had been given attention to making more uniformly enduring every component subjected to wear or stresses. There has been a very general endeavor to insure lubrication of all wearing parts, and to the strengthening of the components that experience had proven could be improved. This was especially true of the smaller and lighter vehicles, where speed means a maximum of wear from operation, and endurance is as necessary as with the slower and more substantial machines.

The exhibitors at Grand Central Palace included those of electric vehicles, and this division was the largest and best of the kind ever seen in America, although the number of makers was but eight, for all of these build machines ranging from small to large capacities, and suited for all purposes for which this type of wagon is adapted. The majority of those making display did not exhibit a complete line because of lack of space, but there was no question of the engineering, design or construction, nor the possibilities of the different forms of power application. The electric department received a great deal of attention, and there was decided interest manifested in new



Main Floor of Grand Central Palace, Seen from the Balcony on the 46th Street Side.

forms for power transmission. As compared with a year ago there has been a very large gain when indicated by percentage.

There was more that was new and especially interesting to the engineer and the mechanical expert in the constructions seen at Grand Central Palace, but at Madison Square Garden the exhibitors had given the more attention to the demonstration of body construction and equipment to facilitate loading and unloading. Here were shown two forms of trailers, the one being the familiar Martin tractor coupled to a dumping body and to a trailer constructed for the street cleaning department of New York, while a Garford truck adapted as a tractor and equipped with a dumping body of 12 tons capacity, a production of the Shadbolt Manufacturing Company, attracted a deal of interest. The Alco exhibit included a dead wagon fitted with channels to receive the rolls of a removable body, which was adapted for dumping as well as for regular cartage, which construction had been utilized with animal wagons for a number of years, but never before used with trucks.

The Locomobile chassis fitted with a special built lumber body, also a Shadbolt design, which was demonstrated with a new type of dead wagon, and a power hoisting dumping body, were two interesting displays, and the Pierce-Arrow, the White, the G. M. C., the Peerless, a Speedwell truck with a body for sand haulage, were demonstrated with dumping bodies, and all save the last mentioned with power hoist. Of the power pump equipment none attracted more attention than the Pierce-Arrow hydraulic hoist, which is claimed to be unusually efficient.

The display of machine tools for manufacturing and garage purposes was also a feature and excited decided attention from the makers of machines and their engineering staffs.

BECOMES CHIEF ENGINEER.

W. B. Engler Returns from Abroad to Assume Charge of G. M. C. Experimental and Research Work.

Announcement has been made by W. L. Day, vice president of the General Motors Truck Company, Detroit, maker of G. M. C. gasoline and electric vehicles, of the promotion of W. B. Engler to the post of chief engineer with entire charge of experimental and development work. Preparatory to his new and larger responsibilities, Mr. Engler has passed the last three months abroad studying European truck design as well as conditions surrounding truck service and operation in continental cities.

For the past three years Mr. Engler has been head of the engineering department of the General Motors Truck Company's heavy duty gasoline truck plant at Owosso.

The announcement of the appointment of L. N. Harrison as manager of its Chicago branch is made by the Kelly-Springfield Motor Truck Company.

OPPOSE VICIOUS LEGISLATION.

Massachuetts Motor Truck Interests Organize to Fight Pending Measures.

A committee consisting of J. S. Hathaway, J. T. Sullivan, J. B. Sullivan, James Fortesque, William H. Bain, John H. Duffell and J. Porter Russell has been appointed as a result of a meeting of representatives of the motor truck and motor car industries, and users of service wagons especially, held at Boston to plan systematic opposition to pending or prospective legislation, particularly a bill that proposes to limit weight of vehicle, weight of load, speed and fix the width of tires of large trucks.

The measure specified is similar to one that was introduced in the legislature a year ago and referred to the present session. It has been claimed by those who favor the bill that the lack of strength of small bridges necessitates the limitation of the weights they should be subjected to.

LEAVES HESS-BRIGHT CONCERN.

Henry Hess Sells Stock to German Company and F. E. Bright Succeeds to Presidency.

F. E. Bright has become president of the Hess-Bright Manufacturing Company, following the purchase of all the stock owned by Henry Hess, by the Deutsche Waffen & Munitions Fabriken, Berlin, Germany, maker of D. W. F. ball bearings. He was formerly vice president and treasurer and now holds the controlling interest.

A. T. Bruegal is secretary and C. L. McCalla is treasurer of the concern. The German parent factory is being enlarged and extensive improvements to the American plant are being made.

ADDS STILL ANOTHER BUILDING.

Willard Storage Battery Company Planning for Largely Increased Demand for LBA Batteries.

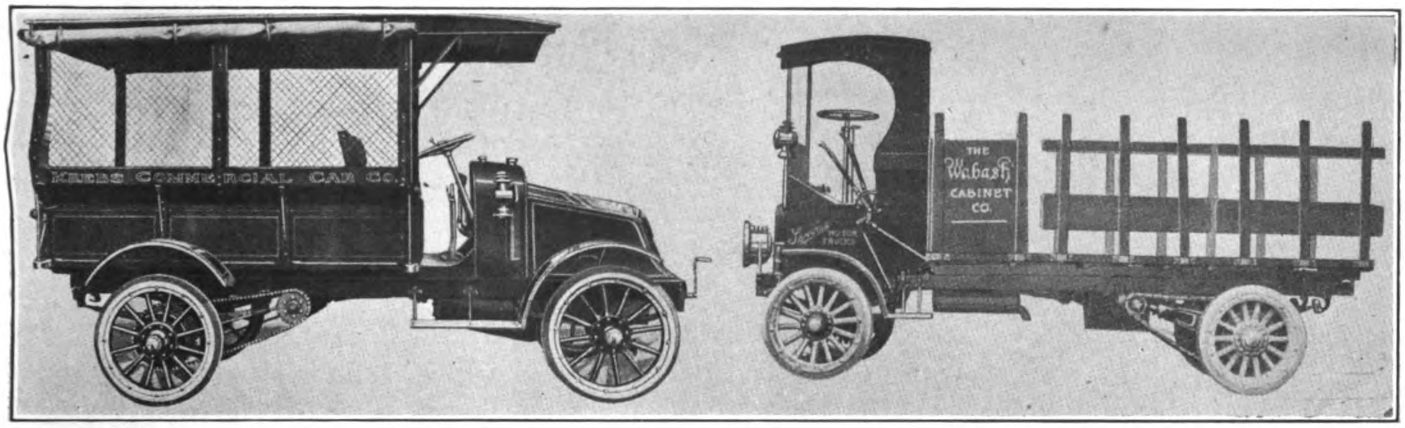
The Willard Storage Battery Company, Cleveland, O., maker of LBA batteries, recently purchased property adjoining its plant No. 1, affording 50,000 feet of additional manufacturing space. Since that time the company has also purchased the plant adjoining the recent addition, a building of brick and steel with 32,-500 feet of floor space.

This furnished the Willard Storage Battery Company with four separate and distinct plants, all conveniently located close together, but not connected. Three are individually equipped for the manufacture of storage batteries and the most recent purchase is intended for future expansion. It will be used for storage purposes only for the present, but when occasion demands it will be equipped for the manufacture of batteries.

NEW MODELS OF WAGONS AND TRUCKS.

Latest Developments of Service Machines Shown at Madison Square and Grand Central Palace--Improvement of Standard Types and Conventional Practise the Feature of the Vehicles Exhibited for the First Time.

AT THE show a number of new machines were seen for the first time, and many of these were particularly interesting. Some were different sizes of designs that are well known, and others were distinctly original. In several instances not a change of any kind was to be noted and with several others the refinements were of so trifling a character as to be hardly worthy of attention, but some productions were in every way interesting from the manner in which the designers had worked out the different problems they met with. It may be said that there is no disposition with men of experience to secure minimum weight at the expense of strength, and yet some of the engineers are emphatic in statements that they have been able to add to the endurance and expected longevity of their creations by the use of carefully selected metals, and elimination of weight where this could be done without lessening the stability of the constructions.



The Krebs Model D Ton Delivery Wagon. The Three-Ton Friction Drive Service Truck.

Krebs in Three Capacities.

The Krebs Commercial Car Company, Clyde, O., showed at Grand Central Palace three delivery wagons, these being models A, B and D. Model B has 1500 pounds capacity, model A 2000 and model D 3000. Model B is shaft and models A and D are chain driven. With these distinctions the brief descriptions will be applied to the two types of chassis as represented by models B and D, but models A and B have a two-cylinder, two-cycle motor and model D has a four-cylinder, four-cycle motor. Model B will be first considered.

This has a motor with 4.5 inches bore and five inches stroke and a horsepower rating of 24.3. The cooling is by thermo-syphon circulation of water through a vertical tube radiator located in front of the dash, and a fan driven by a flat belt from a pulley carried on the crankshaft extension back of the engine case. The ignition is by a Bosch high-tension magneto driven by a cross shaft mounted in front of the motor. The carburetor is an automatic float feed type.

The motor is governed by the Krebs governor, which is mounted at the front of the engine and is driven by the same cross shaft that drives the magneto. This governor is operated by a flexible shaft from the left front wheel and it is maintained that it is in every way automatic and that it can be set to any position, controlling the spark advance as well as the fuel supply, and while it may be set for any desired result it is operated by a lever carried on the steering wheel so that any speed may be had up to the maximum by this control. The governor is usually set for 20 miles an hour for the shaft driven machines and 15 miles for the chain driven. By the control lever both spark and throttle are adjusted to a point where the most efficient work can be done by the engine. It is maintained that with this governor the wagon cannot be made to coast at a rate that would exceed a mile an hour, the speed required to climb the same hill it is descending. When the clutch is engaged the throttle is open sufficiently to maintain a desired speed and when the clutch is disengaged the governor shuts off the gas and the engine cannot race. When the motor is stopped the throttle is open and there is a charge of gas in the cylinder in readiness for starting. To remove the power plant four bolts are taken from the front cross member of the frame and four more bolts from the engine hanger. The motor is carried under a hood of the Renault type.

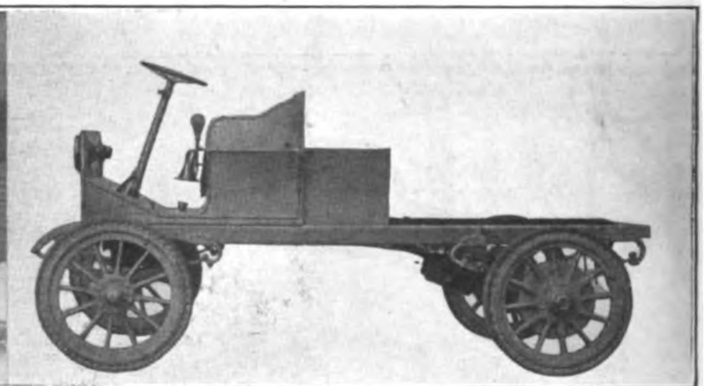
Continuing with model B, the transmission gearset is a Brown-Lipe construction with three forward speeds and reverse, with the control levers at the centre. The drive is by shaft, having two universal joints to a full floating rear axle fitted with New Departure annular ball bearings. The frame is a pressed steel

channel section four inches width and two inches depth, .1875 inch thickness. The springs are semi-elliptic, 40 inches length forward and 50 inches length rear, two inches width. The forward axle is a drop forged steel I section 1.75 by 2.625 inches. The wheels are 34 inches diameter, shod with four-inch pneumatic tires. The drive is left side and the steering gear is an irreversible worm and nut type. The brakes are internal expanding, operating within drums on the rear wheels.

Model A differs from this construction in that it has a rectangular drop forged rear axle 1.75 by 2.25 inches and a jackshaft with drive by side chains and is fitted with three-inch solid tires. Both have a gasoline capacity of 13 gallons, the tank being built in the dash.

Model D has a Rutenber four-cylinder, four-cycle, water-cooled motor with bore of 3.75 inches and stroke of 5.25 inches and is rated at 30 horsepower by the maker. The motor is similarly governed and it is fitted with an electric starter. The transmission gearset of selective type has three forward speeds and reverse. The front axle is a drop forged I section 1.75 by three inches and the rear axle is two by 2.75 inches. The frame is a steel channel section five inches width and it is carried on the same length springs, 2.25 inches width, with .75-inch spring bolts, and auxiliary springs are fitted. The wheels are 36 inches diameter and are fitted with 3.5-inch solid tires forward and four-inch tires at the rear. The wheelbase of models A and B is 100 inches and of model D 115 inches.

The Indiana Two-Ton Wagon.



The Lansden One-Ton Direct Drive Electric Wagon.

Service Three-Ton Truck.

The Service Motor Car Company, Wabash, Ind., exhibited a three-ton truck known as model H, which followed the general design of the smaller machines, this having heavier parts and the proportions being larger. A feature of this construction is the double balanced friction drive. Several improvements have been made in the design, which include adjustable brackets for the jackshaft sprockets, heavier springs, the use of rods instead of cable for brake operation, and the use of roller bearings in the wheels.

Indiana Wagons and Trucks.

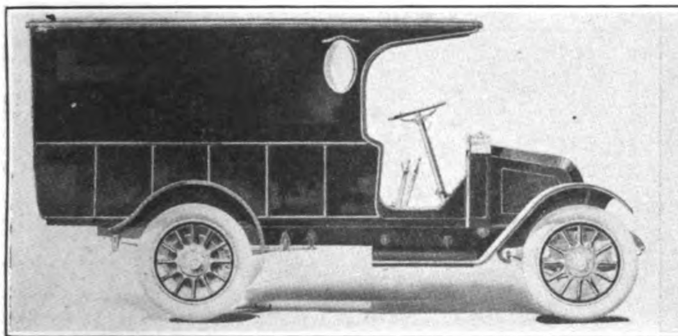
The Indiana wagons and trucks, built by the Harwood-Barley Manufacturing Company, Marion, Ind., which last year showed a 3000-pound wagon at Chicago, were seen at Grand Central Palace, a 1, 1.5-ton and a three-ton chassis being displayed. A two-ton chassis is also built. These constructions follow conventional design. The smallest size is equipped with a Rutenber motor with bore and stroke of four inches, and the ignition is by a Bosch dual system with fixed spark. The clutch is a Hele-Shaw and the transmission gearset is assembled with the jackshaft, it having three forward speeds and reverse, with shafts and gears of nickel steel, the gears having very wide faces. The shafts are mounted on Hyatt roller bearings. The jackshaft is a semi-floating type with shafts of nickel steel. By removing the top or bottom of the housing the differential can be taken out. The drive is by chains to the rear wheels. The frame is a steel channel section five inches width and the forward cross member forms a bumper in front of the radiator. The springs are semi-elliptic, 40 inches length forward and 50 inches length rear, 2.25 inches width. The forward axle is an I section of drop forged steel and the rear axle is a rectangular drop forging. The wheels are 34 inches diameter and are shod with 3.5-inch tires forward and four-inch tires at the rear. The service brake operates on the jackshaft and the emergency brake on the 14-inch drums on the rear wheels. The drive is at the right side with the control levers in the centre. The wheelbase is 135 inches.

The three-ton chassis has a Rutenber motor with bore of 4.75 inches and stroke of five inches and the ignition is by a Bosch dual system. The transmission gearset has Timken roller bearings and the jackshaft is a full floating type with removable shafts of chrome vanadium steel. The differential ends of the shafts are squared and the outer ends have flanges to which the sprockets are bolted. The differential is fitted with a locking device by which the differential may be locked on low or reverse, but automatically unlocks with the shifting of the gears. The frame is a chrome vanadium steel channel section six inches width and it is carried on semi-elliptic springs 40 inches length forward and 50 inches length rear, three inches width. The front axle is an I section 2.25 by 3.25 inches and the rear axle a rectangle 2.75 by four inches. The forward wheels are 36 inches with five-inch tires, and the rear wheels are 40 inches with four-inch dual tires. The wheelbase is 163 inches. The service brake oper-

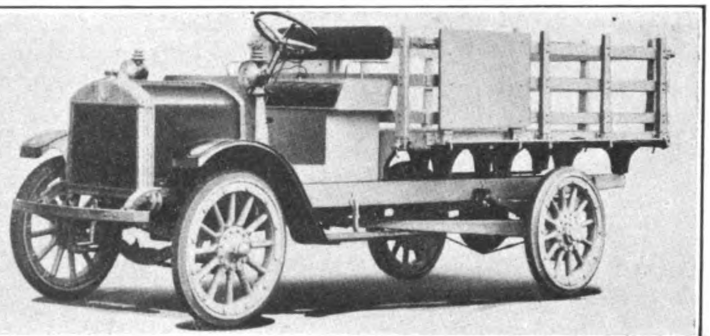
ates on the jackshaft and the emergency brake on 16-inch drums on the rear wheels. The drive is from the right side and the control levers are in the centre. The two-ton chassis differs slightly from this, having a Rutenber motor with bore of 4.125 inches and stroke of 5.25, and has a Bosch dual ignition system with fixed spark and an independent battery system as well. In other respects it is similar save in size of parts.

New Lansden Designs.

The Lansden Company, Newark, N. J., showed a ful line of its machines, these including an ambulance, a 1000-pound express wagon, a one-ton covered express wagon, a 1.5-ton express wagon, a two-ton express wagon and a special one-ton emergency wagon built for the Consolidated Gas Company, which was arranged with a special tool tray under the floor. The machines were all Lansden 1913 types, which design has been described previously, save a one-ton express wagon, which was fitted with the Lansden direct drive. In this the motor is assembled with the full floating rear axle and the drive is by enclosed gears to the differential bevel gear. The power unit is suspended on three points and is well protected against road shocks. The battery is mounted upon the chassis frame under and behind the seat and is easily accessible. The standard battery equipment is 50 type A-4 Edison cells, having a mileage of 50 and a speed of 15 miles an hour maximum.



The Lippard-Stewart Delivery Wagon.



The Universal One-Ton Worm Driven Wagon.

Features of Lippard-Stewart.

Several refinements have been made in the Lippard-Stewart delivery wagons, displayed at Grand Central Palace, one of which is the installation of the steering column with a clamp that firmly secures it to the chassis frame, this preventing the vibration of the steering column and the attendant wear. Some remarkably fine examples of body work were included in the vehicles shown, one of which was an undertaker's wagon, which was fitted with removable side panels and windows, so that with the panels in place it was an unusually ornate casket wagon, and with the windows installed it was converted into a handsome hearse. The change could be made in a very brief period. In addition the platform or bottom of the vehicle was fitted with ornamental metal stops to fit various sizes of caskets, and a roll at the rear permitted the easy movement of a casket either in or out. The interior of the body was handsomely finished in bright mahogany and silver and was lighted by an electric dome light. The line is made by the Lippard-Stewart Motor Car Company, Buffalo, N. Y.

Worm Driven Universal.

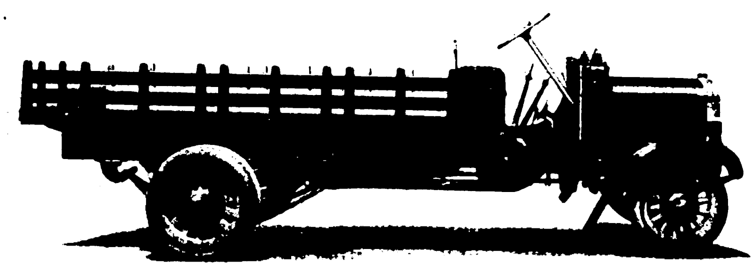
The feature of the exhibit by the Universal Motor Truck Company, Detroit, Mich., at Grand Central Palace, was the one-ton worm driven delivery wagon, which has a wheelbase of 130 inches and a loading space of 120 inches. The construction is in every way conventional, with a four-cylinder, L head, water-cooled motor, with the cylinders cast en bloc, with bore of 3.75 inches and stroke of 5.25 inches, and rated at 30 horsepower. The engine is cooled by a thermo-syphon water circulation through a vertical tube spiral fin radiator, and by a fan driven by a flat belt. The motor is lubricated by a constant level splash system and the ignition is dual, by magneto and battery. The carburetor is an automatic float feed type with a warm air intake. The motor is governed to a speed of 15 miles an hour. The clutch is a single dry plate type and transmission gearset is a sliding gear selective design, giving three forward speeds and reverse. The entire power plant is assembled as a unit and is suspended at three points. The driving shaft operates a worm gear that is assembled with the differential in the full floating rear axle. The frame is a steel channel section six inches width and it is carried on vanadium steel springs 38 inches length forward and 48 inches length rear, 2.5 inches width. The front axle is an I section. The wheels are 24 inches diameter, shod with 3.5-inch solid tires forward and five-inch solid tires rear. The drive is left side and the steering gear is an irreversible worm and block type. The control levers are located at the centre. The service and emergency brakes are internal expanding in drums on the rear wheels.

Interesting Vulcan Line.

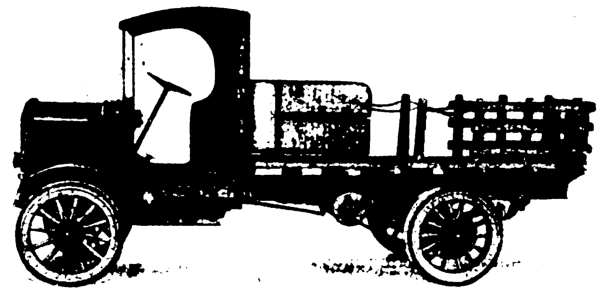
The Vulcan trucks, built by the Driggs-Seabury Ordnance Corporation, Sharon, Penn., were shown for the first time at Grand Central Palace. Of these the 4.5-ton truck was practically the Commer design, but the seven-ton chassis is an entirely new construction. It is a design developed for very heavy work and it is built to have exceedingly long life. The Vulcan chassis are now produced in three, four, 4.5, five, six and seven-ton capacities, but of these the five and six-ton sizes have not been offered for sale, while it is proposed to add to these one and two-ton delivery wag-

ons, which will be ready for the market about April 1. The Driggs-Seabury Ordnance Corporation built many of the components for the American maker of Commer chassis, and these designs have been substantially continued from the three to six-ton sizes, but the ratings of capacity have been reduced and changes have been made that will materially increase the efficiency of the machines. The seven-ton Vulcan has been carefully thought out and it has very large factors of safety throughout.

The motor is a four-cylinder, L head, water-cooled type with the cylinders cast in pairs with bore of 4.75 inches and stroke of 5.5 inches. The S. A. E. rating is 36.1 horsepower. The crankshaft is mounted on three annular ball bearings. The cooling is very efficient, the system having a capacity of 18 gallons of water, which is circulated through the engine by a centrifugal pump, the radiator being either tubular or cellular mounted on trunnions on the chassis frame. The radiation is promoted by a belt driven fan. The lubrication is by a combination of force feed by a gear driven pump and splash. The ignition is by a Bosch dual system, using magneto and battery. It has a carburetor of the automatic float feed type.



The Vulcan Seven-Ton Truck.



The Reo 3000-4000 Pound Delivery Wagon.

The clutch is a leather faced cone and the transmission gearset is assembled as a unit with the jackshaft and is contained in a case carried on three points of support on two frame cross members. The gearset has four forward speeds and reverse and the large shafts and gears are mounted on annular ball bearings. The differential is fitted with a lock. The drive from the jackshaft to the rear wheels is by side chains. The frame is a steel channel section nine inches width and 2.5 inches depth, and is mounted on semi-elliptic springs 48 inches length forward and 55 inches length rear, the rear springs being underslung and having 22 leaves. The front axle is a drop forged alloy steel I section, and the rear axle is a nickel steel drop forging. The wheels are 36 inches diameter with seven-inch front tires and six-inch dual rear tires. The drive is right side and the steering gear is an irreversible worm type. The service brake operates on the jackshaft and the emergency brake on the rear wheel. The wheelbase is 156 inches and the tread is 60 inches forward and 70 inches rear.

New Reo Delivery Wagon.

The new Reo 3000-4000 pound delivery wagon, built by the Reo Motor Car Company, Lansing, Mich., was shown at Madison Square Garden. There are some novel and interesting features of this design, chief of which is the sectional radiator. This is tubular and is made in 24 sections, so arranged that one or more may be removed and the machine used with efficient radiation. The motor is four-cylinder and water-cooled with valves in the side and head and the cylinders are cast in pairs. The bore is four inches and the stroke 4.5 inches. The crankcase is a single casting of aluminum, carrying three main bearings that are adjustable from the outside. The crankshaft is large and of manganese steel. The exhaust valves are in the sides and the intake valves are in the heads of the cylinders.

The motor is cooled by a circulation of water by a gear driven pump, with a belt driven fan and a fan-spoked flywheel. The lubrication is a combination splash and force feed, the bearings being flooded by a plunger pump and splash supplying the other moving parts. The excess from the constant level of oil is drained to the reservoir, filtered and again used. The carburetor is an automatic float feed type with hot air intake, adjustable from the dash. The ignition is by a low-tension magneto and auxiliary battery system. The clutch is a multiple dry disc design, the discs being faced with anti-friction material, contained in a dust tight housing. The clutch shaft is coupled with two universal joints between the clutch and the gearset. The gearset is a selective type, having three forward speeds and reverse, the shifting mechanism being entirely enclosed. The shafts are mounted on Timken and Hyatt bearings. The drive is through a shaft having two universal joints and by side chains. The differential is a four-pinion construction. The frame is a steel channel section 5.5 inches width and the springs are semi-elliptic, 44.5 inches length and 2.25 inches width forward and 42 inches length and 2.5 inches width rear. The front axle is a round steel section and the rear axle is a hammered forging, both fitted with Timken bearings. The wheels are 36 inches diameter with four-inch tires forward and three-inch dual tires rear. The wheelbase is 130 inches. The steering gear is a bevel pinion and sector type. The drive is at the left side and the control levers are in the centre, with spark and throttle levers mounted on the steering column. The motor is governed by a hydraulic governor to 12 miles an hour. The brakes are external contracting, with bands two inches width,

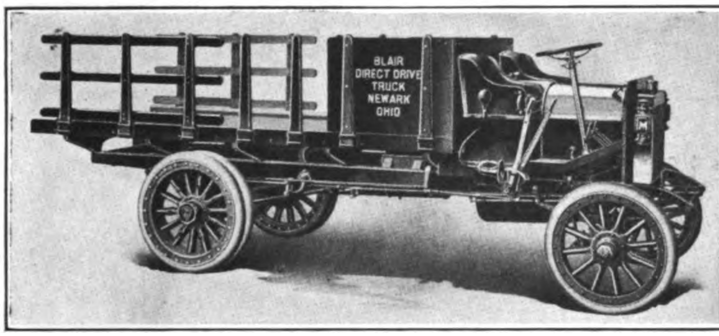
acting on 12-inch drums on the jackshaft and 17-inch drums on the rear wheels.

Blair Worm Driven Models.

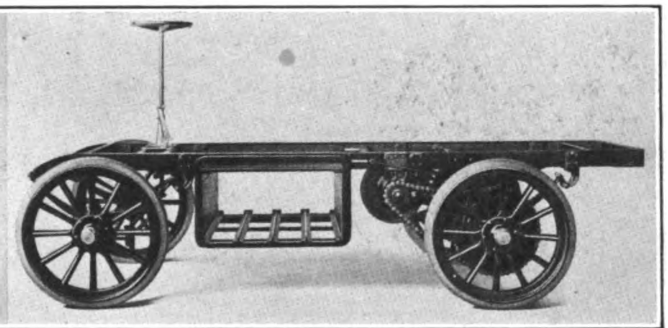
The Blair Manufacturing Company, Newark, O., which exhibited at Chicago a year ago, and which at that time displayed chassis of 1.5, 2.5 and 3.5 tons capacity, showed three chassis of these types at Grand Central Palace, there being no change whatever in the design. The machines are worm driven and differ from any other construction in that a sub-frame of heavy channel steel extends the full length between the two axles. The forward cross member of the chassis frame is very heavy and to this member the sub-frame is hinged or coupled by cast steel brackets and large hardened pins.

The sub-frame is cambered or "necked" back of a large cross member, and at the rear are two more members that carry collars that are fitted to a heavy sleeve that extends at either side and at right angles to the rear axle housing. This sleeve contains the worm. The collars supporting the sub-frame on this sleeve are free to turn, but have no longitudinal motion. Radius rods extend from the ends of the rear axle housing to the centre cross member of the sub-frame, and the tractive effort is transmitted through the sub-frame from the rear axle to the front cross member of the chassis frame. In the sub-frame is mounted the motor and clutch, and the transmission gearset is carried in a heavy case suspended in the sub-frame, with a universal joint in the driving shaft between the clutch and gearset, and a second universal joint in the shaft back of the central cross member of the sub-frame. The rear axle is a full floating construction with a heavy housing, and the chassis frame is suspended on a platform of springs and no matter what the position of the axle through variance of the road surface no excess stress is brought upon the frame or the power plant and the system of transmission, and there is always the same position of the shaft with relation to the motor and gearset.

In other respects conventional design is followed. The motors are four-cylinder, L head, water-cooled types with long stroke, large bearings and enclosed mechanism, fitted with governors, and with dual Bosch ignition. The oiling system is automatic and is claimed to be sufficient for 500 miles. The clutch is a cone with cork inserts and the gearset is selective, having three forward speeds and reverse, the gears being always in mesh and idle only on direct drive. The steering gear is an irreversible construction and all adjustments may be made by turning a single nut at the head of the housing. The radiator is a honeycomb type and is protected by suspension on springs. Both sets of brakes are contracting on the drums on the rear wheels. The seats are on either side of the motor and the drive is at the right side. All the moving parts are provided with means for adequate lubrication. The company is now building a five-ton machine from the same design as the smaller types.



The Blair (Direct Drive) Worm Driven Truck.



The Ward Type ED 8000-Pound Electric Truck.

Ward Electric Line.

The Ward Motor Vehicle Company, New York City, showed at Grand Central Palace four chassis, of 1000, 2000, 4000 and 8000 pounds capacity, of standard design. These machines are entirely conventional, having single motors mounted transversely over the rear axles, with drive by silent chain to a jackshaft and then by chains to the rear wheels. The frames are heavy pressed steel and are mounted on semi-elliptic springs. The axles are rectangular sections, drop forged, fitted with Timken bearings. The batteries are carried in underslung cradles that will take several types of battery. The controllers are a continuous torque design, having four forward speeds and two in reverse. The two brakes are external contracting and are equalized.

The Chase Model M.

The model M Chase delivery wagon, with capacity of 500 pounds, was shown for the first time at Grand Central Palace, though it was placed in the market a number of months before the exhibition. This was the cheapest machine shown and it follows very generally the design of the large Chase constructions. It has a two-cylinder, two-cycle motor with bore of 4.125 inches and stroke of four inches and is rated at 12 horsepower. Like all Chase engines it is air cooled. The lubrication is by mixing the oil with the fuel and the ignition is by a high-tension magneto with fixed spark. The transmission is a planetary type, giving two forward speeds and reverse, and the mechanism is operated in a bath of oil. The drive is to a jackshaft and by double side chains to the rear axles. The frame is of wood and is carried on full elliptic springs forward and a cross spring at the rear that is mounted on extensions of the radius rods. The axles are rectangular, the front being 1.25 inches and the rear 1.375 inches square. The wheels are 36 inches diameter and the

solid tires two inches width. The wheelbase is 84 inches. The control is by a throttle lever on the steering column, the service brake by the right pedal, the reverse the centre pedal, the low speed the left pedal and a hand lever for the high speed. The duplex type brake operates on the rear wheels.

Changes in Stegeman Line.

One of the interesting changes made in the Stegeman chassis, shown at Grand Central Palace by the Stegeman Motor Car Company, Milwaukee, Wis., is the use of a pressed steel chain case that serves as a radius rod. The case is in two parts, the cover is aluminum. In previous constructions an aluminum case was used. The case is built so that the main section carries the expanding brake shoes and at the forward end it is mounted on the jackshaft housing on an eccentric spherical bearing, so that it is free to move and may be adjusted by the eccentric to compensate for wear of the chain. At the rear end the case is carried on a heavy bushing fitted to the axle that compensates for any rotating movement caused by spring action. The case is dust and oil tight and the rear sprockets move in a bath of oil. The frames of these chassis are vanadium steel and extreme strength and lightness are claimed for them. A refinement is an accelerator that may be set or instantly released by a transverse movement of a small foot lever.

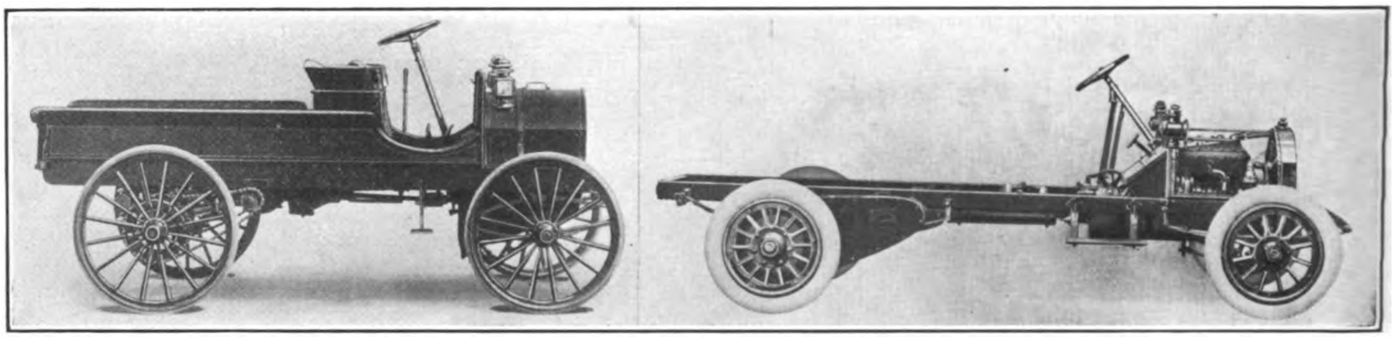
New Atterbury Model.

The Atterbury model A, a chassis with capacity of 1500 pounds, was exhibited at Grand Central Palace, and this was one of the latest of the productions utilizing the concentric gearing or internal gear drive. The maker had made no announcement relative to the machine and its advent created not a little attention. The chassis has a wheelbase of 118 inches and standard tread, and it is claimed that it is unusually heavily built for a machine of its capacity, being constructed to give fast delivery and have extreme endurance.

The motor is a four-cylinder, four-cycle, water-cooled, L head vertical type with bore of 3.75 inches and stroke of 4.5 inches, having an S. A. E. rating of 22.5 horsepower. The engine is built with extreme care and the cylinders are tested under hydraulic pressure to insure against leaks and other defects. The water spaces are large to afford a free circulation of water. The cylinders, piston, crankshaft, camshaft, wristpins, etc., are all ground to size. The valves are large and are at the left side, being completely enclosed. The crankcase is aluminum alloy and is of liberal proportions. The supporting arms are unusually large. The bearings are of generous size and the shafts are carefully heat treated. The lubrication is a combination force feed by a gear pump and splash, the bearings of the crankshaft and connecting rods being flooded and the drainage forming a constant level. The ignition is by a high-tension magneto with fixed spark, the acceleration being by varying the fuel supply.

The clutch is a multiple disc type operated in a bath of lubricant supplied from the motor that is extremely flexible and easy to control. The transmission gearset is a selective type with shafts and gears of 3.5 per cent. nickel steel, the gears being specially heat treated. The shafts are mounted on roller bearings. The arrangement gives three forward speeds and reverse. The motor, clutch and gearset are assembled as a unit with the emergency brake and gearset lever mounted on the cover of the gearset case. The drive is by shaft fitted with two universal joints to a jackshaft that is assembled with the rear axle. This jackshaft is contained in a steel housing fixed to the axle, and pinions at the ends of the shafts mesh with internal gears cut in the inner peripheries of the drums mounted on the rear wheels. The weight is carried by the solid axle. The jackshaft is divided by the differential gear and it is mounted on heavy roller bearings.

The frame is a carbon steel channel section 4.5 inches wide, 2.75 inches deep and .15625 inch thickness. The springs are semi-elliptic and of such length as will secure easy riding. The front axle is a steel drop forged I section, fitted with heat treated spindles of nickel steel and bearings of large size. The steering gear is an irreversible worm and nut type. The brakes are internal expanding in and external contracting on drums on the rear wheels 15 inches diameter and 2.5 inches face. The speed may be governed from 15 to 25 miles an hour maximum, the governor being sealed to insure this result. Care is taken to provide large grease cups and oilers for all wearing parts and the radiator is mounted on springs to eliminate strains from chassis distortion. The claim of high efficiency is made for this construction.



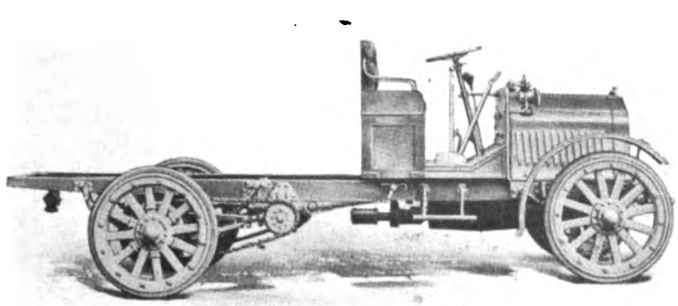
The Chase 500-Pound Delivery Wagon. The Stegeman Two-Ton Truck.

Selden Makes Initial Appearance.

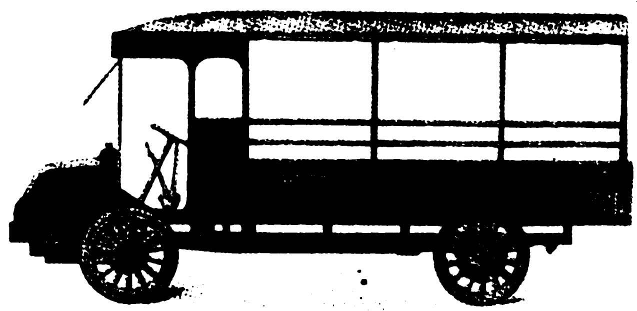
The new Selden 2000-pound delivery wagon, built by the Selden Truck Sales Company, Rochester, N. Y.,

was seen at Madison Square Garden. This machine has a unit power plant with a four-cylinder, water-cooled, L head motor, with the cylinders cast en bloc, and bore of 3.75 inches and stroke of 5.25 inches. The engine is cooled by a circulation of water by a centrifugal pump through a vertical tube radiator and a belt driven fan. The lubrication is by a plunger pump driven by an eccentric from the camshaft that floods the main bearings and timing gears and maintains a constant level in the crankcase base for splash. The carburetor is an automatic float feed type and the ignition is a dual system. The motor is controlled by a sealed governor.

The clutch is a multiple disc construction with six of the 13 plates faced with anti-friction material. The transmission gearset is a selective type with three forward speeds and reverse and the shafts and gears of heat treated nickel steel are mounted on taper roller bearings. There is a universal joint in the shaft between the gearset and the jackshaft. The jackshaft is a semi-floating construction mounted in spherical bearings with shafts 1.375 inches diameter, carried on roller bearings. The drive is by side chains. The frame is a steel channel 5.625 inches width and is suspended on semi-elliptic springs, 42 inches length and 2.25 inches width forward, and 48 inches length and 2.5 inches width rear. The front axle is an I section and the rear axle a drop forging, both heat treated. The wheels are 36 inches diameter, fitted with 3.5-inch solid tires forward and four-inch solid tires rear. The wheelbase is either 125 or 145 inches. The drive is left side with a steering gear of the worm and nut type, and the control levers are at the centre. The service brake operates within drums on the jackshaft and the emergency brake within 16-inch drums on the rear wheels. The maximum speed is 16 miles an hour.



The Selden One-Ton Delivery Wagon.



The Walter-Latil Front Wheel Drive Truck.

Bessemer Adds to Line.

The Bessemer Motor Truck Company, Grove City, Penn., which exhibited at Grand Central Palace, first built a ton wagon, and this year the line has been increased by the addition of models A and C, B being the original. Model C has a capacity of 1500 pounds and model A 3000 pounds, these being built to the initial design with parts proportionate to the capacities, though the 1500-pound machine differs in a number of essential details.

Taking the wagons in the order of their capacity: The motor of model C is a four-cylinder vertical water-cooled type with bore of 3.75 inches and stroke of 4.5 inches and is rated at 25 horsepower. The water is thermo-syphon circulated and the radiation is promoted by the use of a fan. The lubrication is a combination force feed and splash and the ignition is by a high-tension magneto with fixed spark. The clutch is a cone and the transmission gearset is a selective type with three forward speeds and reverse, with nickel steel gears, the shafts being mounted on roller bearings. The drive from the jackshaft is by side chains. The front axle is a rectangular drop forged steel section two by 1.625 inches, and the rear axle is a similar section 2.5 by 1.75 inches. The frame is a pressed steel channel section and the springs are semi-elliptic. The wheels are 34 inches and are shod with 2.5-inch tires forward and three-inch tires at the rear. The wheelbase is 108 inches.

Model B and model A have motors with bore of 3.75 inches and 5.25 inches stroke rated at 30 horsepower, the details of which are the same as with model C, but with these the gearset case is assembled as a unit with the jackshaft and the shafts are mounted on annular ball bearings. The same number of speed ratios is provided. The front and rear axles are Timken constructions and are fitted with Timken roller bearings. The wheels are 34 inches diameter and model B has three-inch tires forward and 3.5-inch tires at the rear, while model A has 3.5-inch tires forward and four-inch tires at the rear. The wheelbase of model B is 120 inches and of model A 136 inches. The brakes are internal expanding in and external contracting on drums on the rear wheels, the bands and shoes being faced with Raybestos. The diameter of the drums on models B and A is 14.75 inches with face three inches width. With model C the brake drums are 13.5 inches diameter and 2.75 inches width.

Decatur Shows Refinements.

The Decatur delivery wagon, shown at Grand Central Palace, built by the Grand Rapids Motor Truck Company, Grand Rapids, Mich., while it has not been materially changed in any detail, has been considerably refined with a view of increasing accessibility. For instance, the dust pan is now suspended by latches, spring retained, so that in a few seconds this may be removed for work or inspection. The seat

unit is similarly secured, and the rear springs instead of being of the platform type are semi-elliptic and are fitted with suspension members that slide on guides on the sides of the chassis frame with the deflection or reflexion, it being claimed that this is more satisfactory than when the customary swinging shackle is used. Extreme care has been taken to afford lubrication to ali moving parts, either by large grease cups or oilers.

Durable Dayton, Modern and Mais.

In the Durable Dayton machines, shown by the Dayton Auto-Truck Company, Dayton, O., at Grand Central Palace, a change has been made from Milwaukee to Wisconsin motors and the radius rods are of Timken construction. With the two-ton chassis the standard wheelbase is 120 inches, but an option is given of 150 inches.

Slight changes have been made in the Modern machines, shown at Grand Central Palace by the Bowling Green Motor Car Company, Bowling Green, O., in that springs have been placed beneath the clutch facings and a honeycomb type of radiator and a new form of radius rod are used. With all models the option of 120 or 136-inch wheelbase and the driver's seat over or behind the motor are given. Previously all seats were behind the motors.

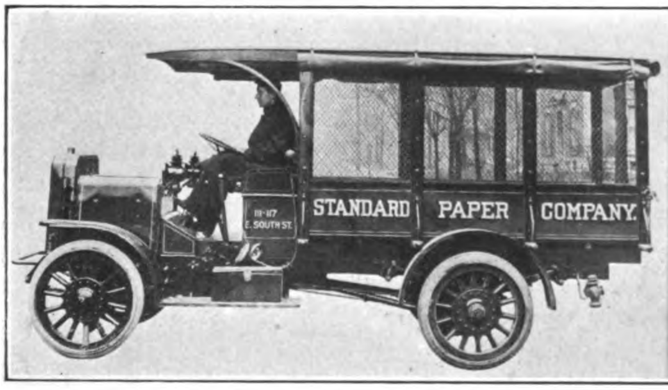
The Mais wagons and trucks, exhibited at Grand Central Palace by the Mais Motor Truck Company, Indianapolis, Ind., now have pressed steel frames instead of channel steel section, for the two, 2.5 and three-ton sizes, but no change has been made with the 1.5-ton chassis. The design has been perfected in that the radius rod ends are fixed in a heavy member that is swivelled to have movement in a block supported between two frame cross members, and this is in effect a universal joint on which the tractive effort is directed. This block is lubricated by copper tubes connected with large grease cups at either side of the chassis frame. In addition the rear and the wheel bearings have been increased, and the sizes of the front axles on the three larger chassis are greater.

Two Pope-Hartford Models.

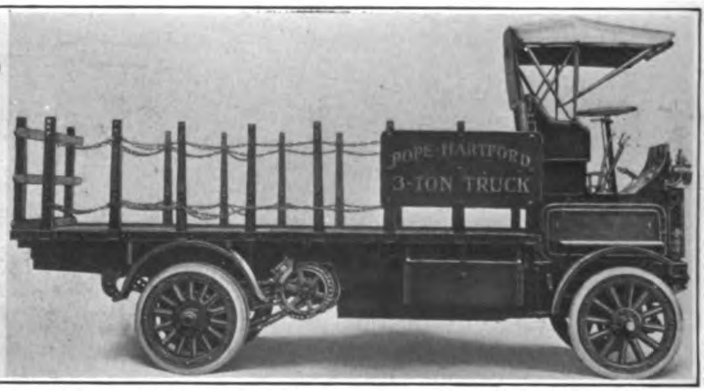
The Pope-Hartford trucks, built by the Pope Manufacturing Company, Hartford, Conn., were shown at Madison Square Garden in the three and five-ton models. The three-ton chassis has a longer wheelbase, a transmission gearset having four forward speeds and reverse, and the service brake on the jackshaft ends has contracting shoes of the locomotive type. The engine is somewhat larger. All of these features are reproduced in the five-ton chassis. The machines were described to considerable length in the preceding issue.

New KisselKar Delivery Wagon.

The feature of the display made by the Kissel Motor Car Company, Hartford, Wis., at Madison Square Garden, was the new 2500-pound delivery wagon, which is claimed by the maker to be the best constructed vehicle of the size ever placed in the market. The motor is the characteristic Kissel design with L head and the valves at the left side, four cylinders, water-cooled, with bore of 4.25 inches and stroke of 5.25 inches, and is rated at 36 horsepower. The motor is lubricated by splash from a constant level of lubricant maintained by an adjustable gear driven pump and by a flow of oil to the bearings and timing gears. The engine is cooled by a circulation of water by a centrifugal pump through a radiating system having a capacity of seven gallons. The radiator is a vertical tube type



The Mais Two-Ton Delivery Wagon.



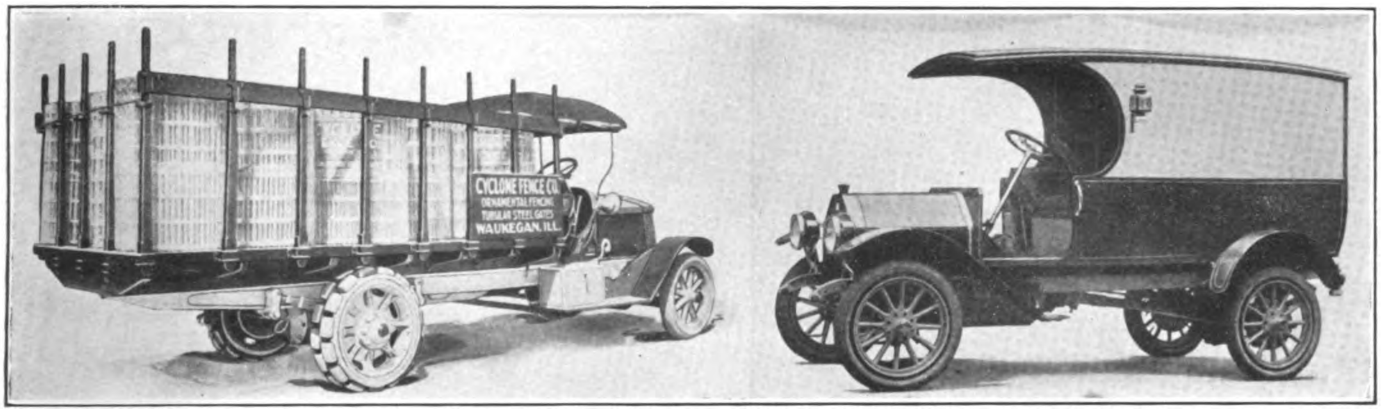
The Pope-Hartford Five-Ton Truck.

with spiral radiating fins and it is carried in a frame of cast aluminum with large radiating fins. The radiator is suspended on housed springs supported by the chassis frame. The ignition is by a Mea magneto which gives the same intensity of spark in any position of the control lever.

The clutch is a leather-faced cone. The motor, clutch and control lever quadrant are carried in a subframe that is mounted at three points, one forward and the others at either side of the chassis frame, on brackets through which vertical guides pass, and these brackets are supported by helical springs below them on the guides, while similar springs resist any upward movement of the brackets on the guides. That is, the sub-frame is protected against shock of any kind by the springs. The drive shaft between the clutch and the transmission gearset is fitted with two universal joints. The gearset and the differential are assembled as a unit and are suspended at a single point forward and at two points at the rear by frame cross members, and the jackshaft is further supported by heavy hangers carried on the frame. The gearset has four forward speeds and reverse, giving three, seven, 13, 16

and two miles an hour. The gearset shafts and gears are very large and the shafts are carried on annular ball bearings. Two inspection plates afford access to the gearset case for examination, and the entire cover may be removed for work. The differential is fitted with a lock that is operated by a foot lever conveniently located in the footboard. The drive is by side chain to the rear wheels.

The frame is a channel section five inches width and this is suspended on semi-elliptic springs, those at the rear being underslung. The length of the forward springs is 38 inches and of the rear springs 50 inches, both 2.5 inches width. The front axle is an I section of drop forged steel and the rear axle a rectangular drop forging. The wheels are mounted on roller bearings and are 34 inches diameter forward and 38 inches rear, with tires 3.5 inches forward and five inches rear. The brakes are internal expanding in and external contracting on drums on the rear wheels. The speed of the motor is governed by a Pierce controller that may be set at any desired point of regulation. The details of construction are well thought out, the provisions for lubrication being especially thorough. Even the starting crank is mounted on the sub-frame. The wheelbase of the chassis is 132 inches and the turning radius is but 25 feet.



The Smith Six-Ton Worm Driven Truck.

The Buick 1500-Pound Delivery Wagon.

Smith-Milwaukee Is Worm Driven.

The Smith-Milwaukee trucks, built by the A. O. Smith Company, Milwaukee, Wis., seen at Grand Central Palace, were shown for the first time in the East and attracted no end of attention, the six-ton chassis being the largest worm driven machine built in this country. The smaller chassis is now rated at 3.5 tons instead of three. The feature of this construction is the combination of the transmission gearset, the driving shaft and the rear axle as a unit, the large torque tube being enlarged at the forward end and joined with the gearset case, and the tractive effort being exerted through this torque tube against the heavy frame cross member that supports the forward end of the transmission case. The relation of the torque tube is preserved by large radius rods that extend to it from the ends of the rear axle housing. The individual clutch type selective gearset is unusually heavy and has constantly meshed herringbone gears. The shafts are each mounted in three large bearings and the entire mechanism is suspended from the cover of the case, so that it may be removed by taking out the cover retaining bolts.

With the increase of capacity of the smaller truck the Continental motor has been changed from a 4.5-inch bore and 5.5-inch stroke, to a five-inch bore and 5.75-inch stroke. With the six-ton chassis, which has a motor with bore of 5.25 inches and stroke of 5.75 inches, the brake linkage has been changed and the better compounded, steel tubing is used instead of rods, and the radius rods are pressed steel tubing of larger diameter. With both chassis a pressed steel housing is used for the rear axle instead of a casting, this affording greater strength and lighter construction. These chassis are noticeable for the steel cored wheels, with the brake drums cast integral, the spokes being semi-circular in section, united by heavy webs. Another feature is the skeleton radiator frame, which is designed to increase radiation.

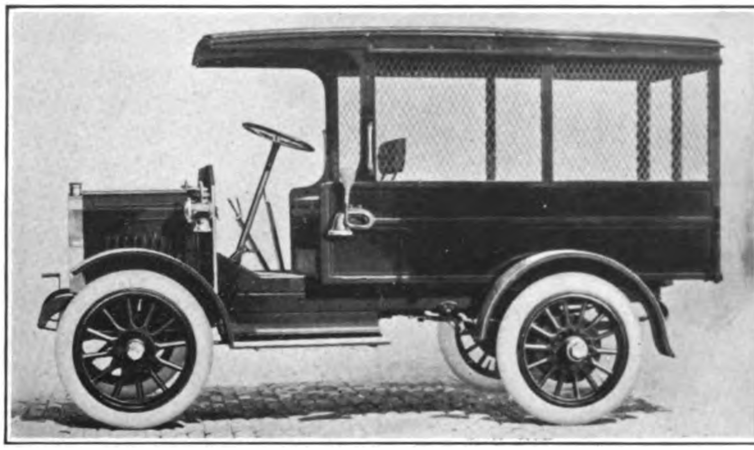
The Standard Motor Truck Company, Detroit, Mich., exhibited its new three-ton machines at Grand Central Palace. These were described in the preceding issue of MOTOR TRUCK.

New Buick Delivery Wagon.

The new Buick delivery wagon chassis was shown for the first time at Madison Square Garden, and this is built in two sizes, having capacities of 1000 and 1500 pounds. The principal difference is in wheelbase, which is respectively 100 and 120 inches, the larger being fitted with 34 by five-inch pneumatic tires instead of 34 by 4.5-inch shoes. The machine is well designed and is carefully built, being intended for fast, light delivery. The motor is a four-cylinder, four-cycle, water-cooled, L head type with the cylinders cast en bloc and the water spaces are very large to insure efficient cooling by thermo-syphon circulation. The diameter of the connections between the motor and the vertical tube radiator is 2.25 inches. Radiation is promoted by a fan driven by a flat belt. The bore of the cylinder is three inches and the stroke five inches, this giving a horsepower rating by S. A. E. formula of 14.4, but with a bore to stroke ratio of 1:1.66 it is claimed that the power actually delivered is approximately double the rating. The motor is fitted with a single detachable

head and the intake manifold passes through the water jacket, thus heating the fuel before it is delivered to the cylinders. The crankshaft is carried on three bearings and is unusually heavy. The valves are enclosed and protected from dust. The motor is lubricated by oil circulated by a gear driven pump that insures a constant level for splash lubrication of all parts, the lubricant passing through a sight feed on the dash. The oil is filtered before passing through the pump. The ignition is by a magneto with a reserve of dry cells. The motor is governed to any maximum speed by a governor that is said to be unusually efficient. The governor is operated by the magneto shaft and is of the centrifugal type. It is located at the right side of the motor. The carburetor is at the left side and the mixture is carried through a cored passage between the cylinders to the right side of the motor and thence through the intake manifold to the cylinders. Governor throttle is at branch of manifold.

The clutch is a leather faced cone and the gearset of the transmission is a selective sliding gear type, giving three forward speeds and reverse, and the drive is by shaft to a rear axle of the three-quarters floating type with the driving shafts mounted on nickel steel Hyatt roller bearings. The driving shaft is enclosed in a large torque tube, the forward end of which is supported by a large yoke coupled to the centre cross member of the frame. Stout radius rods from the rear axle to the yoke maintain the relation of the rear axle. The frame is a pressed steel channel section of large size and it is strongly reinforced. The front springs are semi-elliptic and the rear full elliptic. One feature of the construction is that the power plant, suspended at three points, may be easily removed, and the driving shaft, torque tube and rear axle may be removed as another unit. The front axle is a heavy I section. The control of the gearset and the emergency brake are at the centre and the drive is by a wheel at the left side. The service brake is external contracting on and the emergency brake internal expanding in drums bolted to the rear wheels.



The Flint Light Delivery Wagon.

The Brown Commercial Car.

Flint Is Entirely New.

The Flint delivery wagon, built by the Flint Motor Wagon Department of the Durant-Dort Carriage Company, Flint, Mich., was seen at Grand Central Palace. This is an entirely new construction and while the motor is in front of the driver and the wheelbase is 106 inches, it is maintained that it is but half the length of an animal equipment. The capacity is 1600 pounds. The motor is a four-cylinder, water-cooled, L head type, with bore of 3.75 inches and stroke of 4.5 inches, having a S. A. E. rating of 22.5 horsepower.

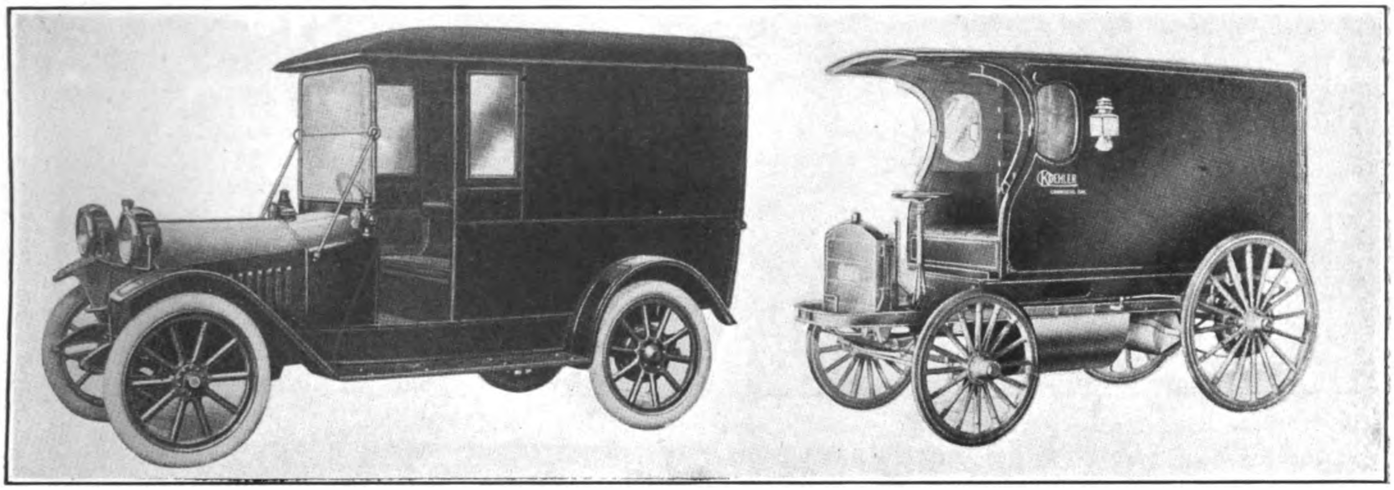
The cylinders are cast en bloc. The construction is in every way conventional. The cooling is by a water circulation by a centrifugal pump through a vertical flat tube radiator and by a 16-inch fan driven by a flat belt. The lubrication is by splash in a constant level pool in the crankcase maintained by a gear driven pump. The ignition is by a dual system with Remy magneto and storage battery. The motor is governed by a ball governor set for a maximum of 18 miles an hour.

The clutch is a leather-faced cone, 14.25 inches diameter and three inches face, with two universal joints between the motor and the transmission gearset. The gearset is a selective type having three forward speeds and reverse and all the gears have inch faces. The shafts are carried on roller bearings. The drive is by a shaft 1.25 inches diameter with two universal joints between the gearset and the differential. The power plant, clutch and gearset are carried in a sub-frame that is supported at two points from the forward cross frame member, and the rear end is suspended from a yoke carried on a bracket on the centre cross frame member.

The frame back of the centre is strongly braced with gussets and diagonals from the side to the centre and rear members. The rear axle is a full floating construction and just inside the spring seats the ends of the torque rods are fixed on pivots that permit a side or transverse movement. The forward ends of the rods are secured to a curved member that has a small yoke that is connected with a member so designed as to pivot transversely in a bracket fixed to the centre cross member of the frame. The forward end construction is in reality a gimbal that will compensate for any chassis distortion, and as the forward yoke

connection of the rods will turn in the curved member, the design is termed a triple-acting joint connection by the builder. The pinion gears and shafts of the rear axle are 3.5 per cent. nickel steel. The differential bearings are Hyatt roller and New Departure for the shafts and hubs. The forward axle is an I section 1.75 by 2.625 inches of drop forged steel. The springs are semi-elliptic, 40 by 2.25 inches forward and 48 by 2.25 inches rear, with all shackle bolts hardened and ground and fitted with grease cups. The frame is a channel section of large size. The steering wheel is at the left side and the gear is an irreversible screw and nut type. The hand levers are at the centre and the spark and throttle levers are mounted above the steering wheel. The service brake is external contracting on a 10-inch drum on the shaft directly back of the gearset case, the band being 2.25 inches width. The emergency brake has shoes two inches width operating within 16-inch drums bolted to the rear wheels. The wheels are 34 inches diameter and are shod with three-inch solid tires forward and 3.5-inch solid tires and four inches length. The bearings are bushed with Parsons' white bronze.

The connecting rods are steel drop forgings, heat treated, with bearings 2.5 inches length, and the wristpin diameter is an inch. The big end bearings are Parsons' white bronze and the small ends are bronze bushed. The motor is lubricated by oil circulated by two plunger pumps driven by eccentrics on the camshaft, and it is carried by a system of tubing to the main bearings and the timing gears, and drains into the crankcase, where a constant level is maintained for splash lubrication of the camshaft bearings, cams, valve tappets, connecting rods, pistons and cylinders. The oil is filtered and there is provision for cleaning the filter. The motor is cooled by a circulation of water forced through a vertical radiator by a centrifugal pump and a fan driven by a flat belt. The radiator is suspended on coiled springs and is insured against stresses of any kind from chassis distortion. The carburetor is an automatic float feed type. The ignition is supplied by a magneto of Remy manufacture.



The Hupmobile 1000-Pound Delivery Wagon.

The Koehler 1600-Pound Delivery Wagon.

rear, or 4.5-inch pneumatic tires forward and five-inch pneumatic tires rear.

Brown Uses Internal Gear.

The Brown commercial wagon, built by the Brown Commercial Car Company, Peru, Ind., was shown for the first time at Grand Central Palace. This is designed for fast, light delivery, having capacity of 1500 pounds, and the principal feature is the use of the internal or concentric gear drive. This machine has a unit power plant with a four-cylinder, four-cycle, L head, water-cooled, vertical motor, with the cylinders cast en bloc, with bore of 3.75 inches and stroke of 5.25 inches, having an S. A. E. rating of 22.5 horsepower. The crankcase is of aluminum and the lower section may be removed without changing the crankshaft bearings. The water spaces are liberal to insure efficient cooling and the cylinders are carefully finished. The pistons are a special gray iron and are accurately ground, being fitted with four eccentric compression rings. The crankshaft is a high grade steel drop forging, heat treated, 1.75 inches diameter, with front, centre and rear bearings respectively 2.75, three

The clutch is a dry plate design, with 27 plates, 14 of which are faced on either side with an anti-friction material. The transmission gearset is a selective type giving three forward speeds and reverse, the shafts being mounted on annular ball bearings, and the gears being of heat treated nickel steel. The drive is through a 1.75-inch tubular shaft fitted at either end with dust proof universal joints, and the torque and driving strains are taken by two large tubes extending from the brake spiders to a cross member in the centre of the chassis. The forward ends of the tubes are mounted with a globe that is carried in a socket bushed with bronze, contained in a bracket on the cross member. The shaft extends through an opening in the heavy drop forged rear axle web to a countershaft bolted at the rear of the axle, and a pinion meshes with the bevel gear of the differential. Pinions at the outer ends of the shafts mesh with the internal gears bolted to the rear wheels. The wheels are carried on two rows of annular ball bearings. The driving gears are enclosed and are protected against dust and abrasion. The front axle is a drop forged steel I section with spindles

of nickel steel with annular ball bearings. The frame is of pressed steel channel with width of 4.5 inches and depth of four inches at the centre, and the springs are semi-elliptic, 40 inches length forward and 50 inches length rear, two inches width. The control is to a steering wheel at the left side with gearset and emergency brake levers in the centre, and pedals for the clutch and service brake.

Hupmobile Delivery Model.

The Hupmobile delivery wagon chassis, shown at Madison Square Garden by the Hupp Motor Car Company, Detroit, Mich., does not differ from the regular Hupmobile touring car chassis design, but it has auxiliary helical springs fitted at the rear which take a part of the load when the springs are compressed by a load, and the motor is fitted with the Pierce speed controller, by which an automatic throttle in the inlet manifold is operated by a centrifugal governor driven by flexible shaft from the left front wheel. When a predetermined speed of the machine has been reached the controller becomes operative, and below that speed control is by accelerator operated by foot, permitting use of full power of motor on low or second speed.

Koehler Commercial Car.

The Koehler commercial car, built for the H. J. Koehler Sporting Goods Company, New York City, which was new last year, was shown at Grand Central Palace, and it had been somewhat improved, one refinement being the betterment of the high speed clutch mechanism of the planetary transmission. Another is the adoption of an internal expanding brake, the shoes of which are operated within the drums that carry the sprockets on the rear wheels by cams, and which afford a very large area of braking surface. The rear sprockets are integral with the brake drums and the construction gives an efficient brake that is easily adjustable as well as extremely efficient and practical.

Sullivan Delivery Wagons.

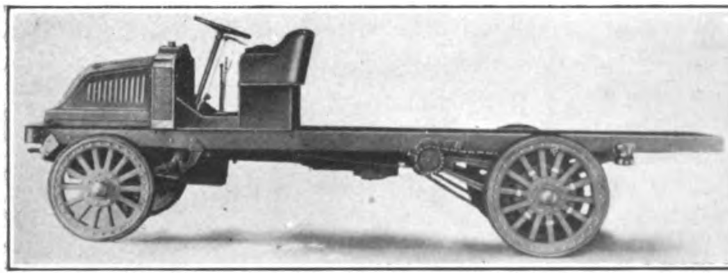
Several minor changes have been made in the Sullivan delivery wagons built by the Sullivan Motor Car Company, Rochester, N. Y., shown at Grand Central Palace and these include the incorporation of the transmission with the jackshaft, the use of two universal joints in the driving shaft, the use of service brakes on the jackshafts, and a heavier front axle with the 1500-2000 pound chassis, and the fitting of three-inch tires instead of 2.5-inch shoes on the rear wheels. The smaller chassis has not been changed in design from previous productions.

Maccarr Is a New Product.

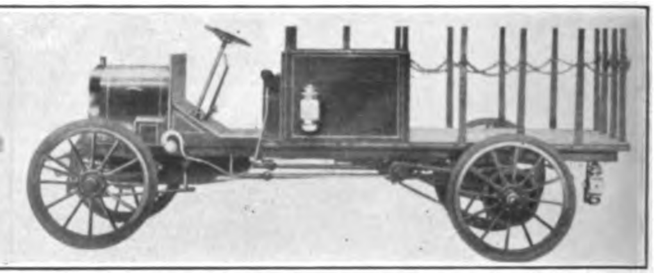
The Maccarr delivery wagon, built by the Maccarr Company, Allentown, Penn., was shown for the first time at Grand Central Palace. It is the product of a concern of which J. M. Mack is designer and executive, he having been for years identified with the Mack Bros. Motor Car Company and later with the International Motors Company. The machines are built in two sizes, 1500 and 2000 pounds. The smaller machine is equipped with a unit power plant with cylinders having a bore of 3.75 inches and stroke of 5.5 inches, with a claimed S. A. E. rating of 28 horsepower. The cylinders are cast en bloc. The engine is water-cooled and is lubricated by splash in a constant level of oil maintained by a pump and by direct circulation to the main and connecting rod bearings. The cooling is by a circulation of water through a tubular radiator by a gear driven pump and a fan mounted on a bracket carrying a ball bearing and driven by a flat belt. The ignition is by a Bosch dual system. The carburetor is an automatic float feed type. The motor is governed to any speed between 500 and 1000 revolutions by a sealed governor.

The clutch is a multiple dry disc construction that is easily removable. The drive is through a selective type sliding gearset giving three forward speeds and reverse and a shaft having two universal joints to the Timken full floating rear axle, the shafts being of special alloy steel and having Timken roller bearings. The front axle is a drop forged steel I section of special construction. The frame is a steel channel section carried on semi-elliptic springs forward, 38 inches length and two inches width, and a platform at the rear with side members 48 inches length and two inches width, with a cross member 39 inches length and two inches width. The wheels are 36 inches diameter with 4.5-inch pneumatic tires. The steering gear is an irreversible worm and sector type and the brakes are internal expanding in and external contracting on drums 17 inches diameter and 2.5 inches width on the rear wheels, both sets being equalized. The drive is left side with the control levers at the centre and spark and throttle levers on the steering column. The wheelbase is 114 or 126 inches.

The larger chassis differs from the smaller in that it had wheelbase of 126 or 138 inches, the drive is by shaft, countershaft and side chains, the springs are 2.5 inches width, the front axle is a heavier drop forged I section and the rear axle is hammer forged from nickel steel with the spring seats forged integral, the service



The Kelly Model K-40 Three-Ton Truck.



The Sullivan 1500-2000 Pound Delivery Wagon.

brake is internal expanding in drums on the counter-shaft and the emergency brake is internal expanding in drums on the rear wheels, and the 36-inch wheels are shod with three-inch solid tires forward and four-inch solid tires at the rear.

Croce Makes First Appearance.

The Croce wagons and trucks, built by the Croce Auto Company, Asbury Park, N. J., were shown for the first time at any exhibition, although the company has been producing them for a number of years. These machines are constructed of standard components, having Wisconsin motors, Brown-Lipe transmission gearsets, Spicer universal joints in the transmission shafts, Timken axles, Bosch magnetos and Schebler carburetors, and a number of exclusive features covered by Croce patents. The sizes built are 1500, 3000, 4000, 6000 and 10,000 pounds, but limited space prevented the display of the 3000 and 10,000-pound machines.

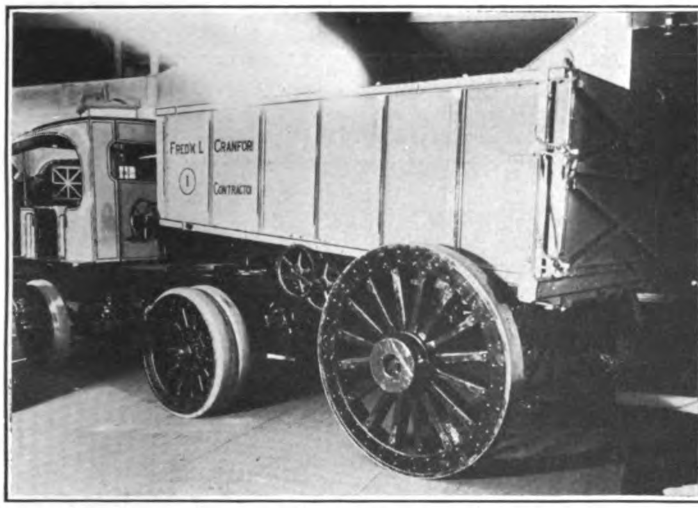
The 1500-pound chassis has a motor with bore of 3.75 inches and stroke of five inches, with the cylinders cast en bloc, and the others are with T head engines with the cylinders cast in pairs, with bore of 4.25 inches and stroke of five inches for the 3000 and 4000-pound chassis, and with bore of 4.75 inches and stroke of 5.5 inches for the 6000 and 10,000-pound chassis. The main difference in these machines aside from the engines is in size of parts, all having the Croce clutch, in which made integral with the cone is a sleeve on which are two collars. The clutch shaft extends through this sleeve, the sleeve enclosing the clutch spring, the thrust bearing and a universal joint, and the roller bearing of the clutch acts as a brake and minimizes the spinning of the clutch. On the 1500-pound chassis the withdrawal of the clutch engages a cone brake on the shaft with a member included in the universal joint mounted on the front side of the transmission gearset case, and as this cone is faced with asbestos its operation is noiseless and the wear negligible.

The Croce radiator has a base of cast brass and the construction is the tube principle used for steam boilers. The tubes are horizontal and are expanded and are soldered. The tubes may be easily repaired in the event of leak, but a temporary repair may be made by plugging the open ends of the defective tube with corks, and the machine may be used without reduced efficiency. Another device is the bumper, which is built with heavy rods carried on the spring horns on which are mounted the bumper guides. There is a longitudinal movement permitted, heavy helical springs maintaining the bumper at the greatest distance from the frame. As the springs are compressed the bumper is moved on the rods, the shock being compensated proportionate to the strength of the spring. The wheelbase of each model in order of size is 100, 120, 144, 156 and 192 inches.

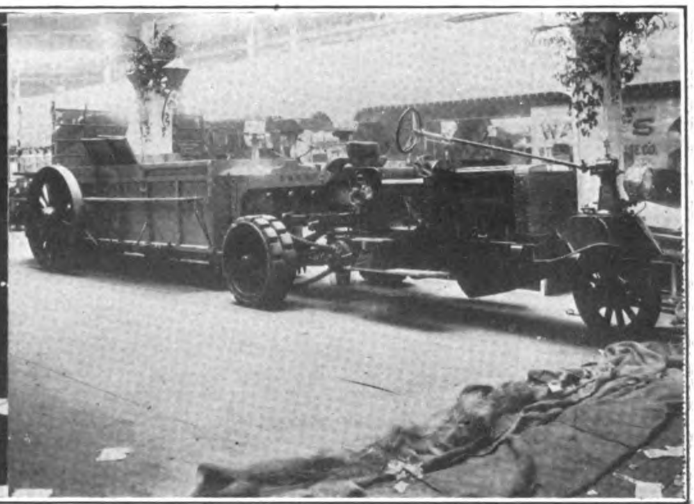
Increase in Dart Line.

The Dart Motor Manufacturing Company, Waterloo, Ia., which last year built a single chassis, this being equipped with a double-opposed motor, showed at Grand Central Palace model B, of 2000 pounds capacity, and model C, of 3000 pounds capacity. The construction is similar throughout, although the machines differ somewhat in detail. The model B has a wheelbase of 114 inches and the motor is a four-cylinder, water-cooled, L head type with the cylinders cast en bloc, the bore being 4.0625 and the stroke 4.5 inches, with a rating of 25-30 horsepower. The motor is cooled by a circulation through a honeycomb radiator by a centrifugal pump. The radiator is mounted by ball and socket trunnions on the frame. The lubrication is a constant level system fed by a gear driven pump, and the ignition is by a Bosch magneto with a fixed spark. The carburetor is an automatic float feed type.

The clutch is a cone, leather faced, with springs beneath the facing to insure ease of engagement, and the drive is through a gearset of a selective type assembled with the jackshaft, having three forward speeds and reverse, the gears having .75-inch faces and the gears and shafts being of nickel steel and heat treated. The jackshaft is a three-quarters floating construction, with shafts of heat treated nickel steel 1.5



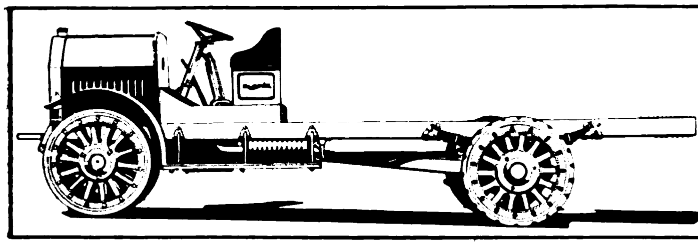
The Garford Truck with 12-Ton Body.



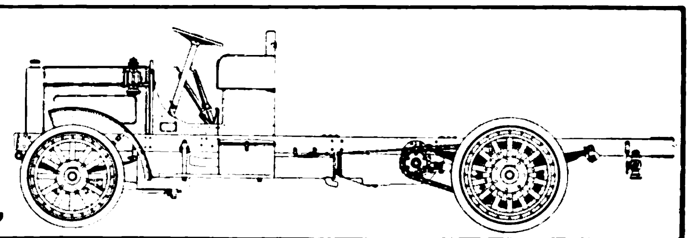
The Martin Tractor and Street Cleaning Body.

inches diameter, mounted on roller and annular ball bearings. The front axle is a drop forged I section with nickel steel steering knuckle spindles, and the rear axle is a drop forged rectangular steel section. The frame is pressed steel channel of liberal proportions and is mounted on semi-elliptic springs, the forward set being 37 inches length and two inches width, and the rear set 46 inches length and 2.25 inches width, of electro silica-manganese steel. The drive is at the left side and the control levers are in the centre. The steering gear is a screw and nut irreversible type. The service brake has contracting shoes 2.5 inches width acting on a drum 14 inches diameter, and the emergency brake has expanding shoes three inches width operating within the same drum, which are bolted to the rear wheels. The 36-inch wheels are shod with 2.5-inch solid tires forward and three-inch tires at the rear.

The model C chassis has a four-cylinder L head motor with bore of 4.25 inches and stroke of five inches, rated at 35-40 horsepower, with the cylinders cast in pairs. The motor is cooled by water circulated by a centrifugal pump. The honeycomb radiator is similarly mounted. The ignition is by an Eisemann magneto with automatic spark advance. The clutch is a cone type and the transmission gearset is the same with .825-inch face gears. The jackshaft is the same. The frame is similar material as model B and the springs are 40 inches length and 2.5 inches width and 48 inches length and 2.5 inches width for the front and rear respectively. The axles are the same construction and the wheels are 34 inches forward, 38 inches rear, shod with 3.5-inch tires. The drive is left side with the control levers at the centre. The machine has the special Dart foot control, by which the accelerator may be set at any desired position, but this may be instantly changed or released.



The Studebaker Three-Ton Truck.



The Peerless 1913 Chassis.

Mais Designed Studebaker.

The Studebaker Corporation, Detroit, Mich., showed at Grand Central Palace a three-ton vehicle designed by A. F. Mais, which has innumerable features. While it is driven by concentric gears and so constructed as to afford a straight line drive when loaded, these are by no means all of its features. The machine is practically built in four units, all of which may be removed as assemblies, and the purpose has been to obtain a degree of flexibility that will insure against stresses from distortion. The power plant is a unit and with it is mounted the steering column and the clutch and service brake pedal shafts, as well as the sight feed gauge for the lubrication system. Rings are placed in the motor arms and back of the gearset case so that the assembly may be hoisted out after loosening five bolts. The steering gear can be removed by taking out two bolts, and the control can be taken out with the removal of four bolts.

The motor is a T head type with cylinders cast in pairs with bore of 4.375 inches and stroke of 6.5, this giving a bore to stroke ratio of 1:1.495. The crankcase is a solid casting. The crankshaft is carried on three large annular ball bearings and all the cam and gear shafts have similar bearings. The lubrication is an automatic force feed that sprays the bearings and timing gears. The cooling is by water circulated by a centrifugal pump through a radiator and by an 18-inch fan that draws a current of air through the radiator and a diaphragm directly on to the motor. The ignition is an Eisemann magneto with automatic spark control. The motor is regulated by a governor driven off the transmission gearset countershaft.

The clutch is an expanding type with six shoes of cast aluminum alloy that have wedge-shaped tongues engaging with similar grooves in the inner periphery of the flywheel rim. The shoes are kept in engagement by helical springs that are compressed to engage or disengage them by radially acting arms that are connected with the clutch pedal. These shoes are operated in oil. The design is maintained to give increased area of surface contact, and while the shoes cannot slip the smooth surface prevents harsh engagement. The transmission gearset is a selective sliding gear type with four speeds forward and reverse, but no direct drive, the fourth ratio being in excess of the engine shaft movement. The drive is by shaft to a jackshaft or countershaft with a torpedo-shaped housing mounted forward of the rear axle. The driving shafts carry pinions at the outer ends that mesh with internal gears in drums on the rear wheels. The long radius rods extend from the axle forward to the centre cross member of the frame, on which they swing with the vertical movement of the rear axle. Ahead of the countershaft housing is a bracket and two large drums mounted on the driving shaft. On these drums the service and the first emergency brake bands constrict. The service brake is the band nearest the housing and the first emergency brake is the second, both being of a size. The second emergency brake, which is operated by a lever at the left of the driver, actuates long shoes in which are V shaped grooves which engage with V shaped collars integral with the internal gear drums. Because of the form the brake is self-adjusting so far as contact is concerned, and the brak-

ing area is very large. All the brakes are equalized.

The frame is a steel channel section six inches width and three inches depth and is carried on long semi-elliptic springs that have a very flat arc, permitting low suspension. The front axle is a reverse Le Moine type, I section, drop forged from chrome nickel steel and the rear axle is an I section of the same metal. These have annular ball bearings and are fitted with wheels 38 inches diameter, having five-inch single tires forward and five-inch dual tires rear. The drive is right side and the control levers are at the centre. The chassis is built in two sizes, with wheelbase of 144 and 180 inches. Other sizes of the same design are to be built by this company.

Little Change in Peerless.

But little change has been made in the Peerless trucks, built by the Peerless Motor Car Company, Cleveland, O., and shown at Madison Square Garden, the improvement being in the operating of the emergency brake, which has been changed so that the equalizing drawbar is carried in guides below the chassis frame, instead of using a shaft that projected through the frame members at either side. This eliminates the possibility of weakness developing at the shaft openings.

New Five-Ton Packard.

The new five-ton truck built by the Packard Motor Car Company, Detroit, Mich., was exhibited at Madison Square Garden. In general appearance it is an enlarged three-ton design, but it has some features of construction that are new, and some of these have been incorporated with the three-ton machine, which differs from the smaller two-ton chassis. The Packard design was identical for the two and three-ton chassis until the production of the largest size. The two-ton chassis has not been changed.

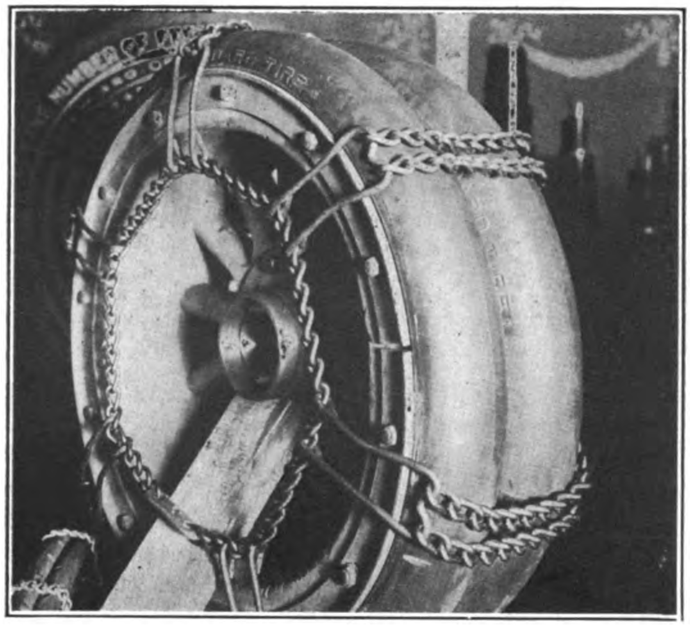
The three-ton chassis is now fitted with the new jackshaft hanger designed to carry the large contracting brake shoes of the locomotive type that act on drums carried on the jackshaft outboard ends. This construction gives metal-to-metal friction surfaces, large braking surface area, and makes possible adjustment that insures equalized braking effect. This same type of brake is used on the five-ton machine. The rear axle is a very heavy I section and on this the heavy semi-elliptic springs are seated. The spring saddle is shaped with side members that extend nearly the full depth of the spring and the ends of the saddles are transversely grooved. The spring clips are seated in these grooves and the ends extend through the upper flange of the axle and are secured by nuts. The form of the saddle clamps the springs and prevents movement of the leaves. The ends of the springs are mounted in members bolted under the side members of the frame in which they move with the deflection or reflexion. This design eliminates the usual wear of spring shackles and bolts.

B. A. Gramm's Trucks.

B. A. Gramm's trucks, built by the Gramm-Bernstein Company, Lima, O., were seen at Grand Central Palace. These were exhibited for the first time and were noticeable for the suspension of the motor on a sub-frame supported by lugs mounted between helical springs, for the transmission gearset giving four forward speeds and reverse, and the electric lighting and starting system. These machines, of two and 3.5 tons capacity, were described at length in the January issue.

Changes in Sternberg Line.

Several changes have been made in the motors and transmission gearsets of the Sternberg trucks, built by the Sternberg Manufacturing Company, Milwaukee, Wis., which were exhibited at Grand Central Palace. In the motors the stroke has been lengthened, the bore being 4.25 and the stroke 6.75 for the two and three-ton chassis, and 4.5 inches bore and 6.75 inches stroke for the four, five and six-ton chassis. The drop forged timing gears have been made larger and with wider faces, the wristpins are 1.25 inches diameter and



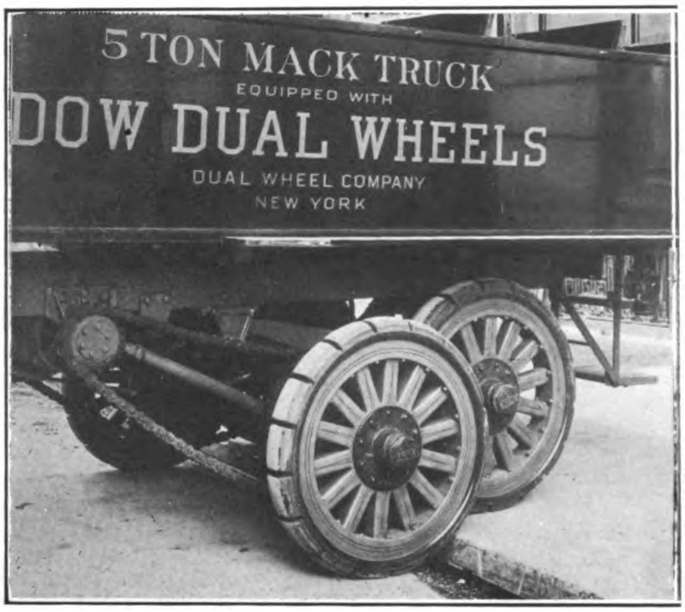
The New Truck Equipment Made by the Weed Chain Tire Grip Company.

made of nickel steel, the wristpin bearings in the pistons bushed with bronze, the camshafts have been increased in size and are made of heat treated nickel steel, the camshaft bearings increased in size, the pushrods increased in diameter and fitted to cast iron bushings, the valve mechanism enclosed, the valve caps made of tempered steel, the oil reservoirs and the size of the inspection plates increased, and a new governor adopted. In the gearset the shafts have been shortened, the pitch line of the gears changed and the number of dogs increased, a spline shaft is used instead of a square shaft, and the shafts are mounted on double row annular ball bearings instead of single row.

New Willys Utility Truck.

The Willys utility truck was included in the exhibit of the Gramm Motor Truck Company, Lima, O., at Madison Square Garden. This machine is rated at 1500 pounds capacity and it has a four-cylinder, water-cooled motor, with bore of four inches and stroke

of 4.5 inches, rated at 30 horsepower. The cylinders are cast singly. It has a five-bearing crankshaft and is cooled by thermo-syphon circulation through a radiator and a belt driven fan. The motor is lubricated by a constant level of oil maintained by a pump that floods the main bearings and the timing gears. The ignition is by a Remy magneto and battery. The clutch is a leather faced cone and the selective type transmission gearset gives three forward speeds and reverse. The gearset is assembled with the jackshaft. The drive is by side chains. The frame is a pressed steel channel section and is suspended on semi-elliptic springs 45 inches length and 2.25 inches width forward and 50 inches length and 2.5 inches width rear. The front axle is an I section and the rear axle is rectangular, both drop forgings. They are fitted with Timken bearings. The wheels are 36 inches diameter and are equipped with 3.5-inch tires at front and rear. The drive is at the right side and the steering gear is an irreversible worm and worm gear type. The control



The Dow Dual Wheel Equipment Installed on a Five-Ton Mack Truck.

levers are at the centre. The service brake is external contracting on the jackshaft and the emergency brake is internal expanding in drums on the rear wheels. The wheelbase is 120 inches and the tread 60 inches. The motor is regulated by a governor to a speed of 18 miles an hour.

LaFrance Gasoline-Hydraulic.

The LaFrance gasoline-hydraulic trucks were exhibited at Grand Central Palace by the Hydraulic Truck Sales Company, New York City, for the first time at any exhibition, but these machines are well known because in them is used the Manly hydraulic drive, in which a volume of oil is circulated through two motors by a pump actuated by a 48 horsepower gasoline motor, and from these motors the drive is by chains to sprockets on the rear wheels.

Sanford Shows New Model.

The Sanford Motor Truck Company, Syracuse, N. Y., exhibited at Grand Central Palace a new 3000-pound delivery wagon known as model L, which follows in every way the design of model K, the 2000-pound wagon, save that the wheelbase is 118 inches, the frame is a five-inch channel section and the springs, axles, tires and wheels are larger. The features of these machines are the unit power plants, the oiling system and governor of the motor, the Sanford clutch release, the transmission gearset and the provision for lubricating all moving parts.

Waverley Increases Rated Capacity.

The Waverley Company, Indianapolis, Ind., at Grand Central Palace, exhibited its 1000-pound delivery wagon, which is precisely the same design as the 600-pound wagon of 1912, with the components proportioned to give the required capacity and endurance. In this machine the motor is suspended transversely in the chassis and the drive is by silent chain to a countershaft and through this by herringbone gears to the gear incorporated with the differential in rear axle.

Dow Dual Wheel.

Incidental to the showing of vehicles inside was the exhibition of the Dow dual wheel equipment, which was used to drive a five-ton truck chassis fitted with a passenger body between the exhibition buildings. It is the invention of Alexander Dow and is an adaption of the bogey truck principle. The regular vehicle axle has mounted on the spindles what is known as an equalizing bar, and in the Dow construction this bar is so shaped that at either end of the bar is fitted an axle spindle on which is mounted a wheel in the regular manner, but the wheels overlap, the forward wheel being sufficiently outside of the rear wheel to insure good clearance. Both wheels are driven from a jackshaft sprocket and a brake operates on each wheel. The design gives four points of support to the rear axle instead of two, and the change of any one of these greatly reduces the movement of the axle and the consequent spring action is minimized. It is also claimed for the Dow dual wheel system that skidding is practically eliminated and the wear of tires much reduced. The tread of the vehicles is increased but an inch or two and the overlap of the wheels gives a distance of perhaps 21 inches with 36-inch wheels between the two lines of support. It is maintained that this construction can be adapted to forward wheels should this be desired.

Another interesting exhibit was the new truck tire chain displayed by the Weed Chain Tire Grip Company, which is practically explained by the accompanying illustration.

The Electric Storage Battery Company, Philadelphia, Penn., is distributing a series of four interesting booklets recently issued, which are devoted to Exide batteries and their use, both for electric vehicles and for gasoline machines, for engine starting, ignition and lighting. Two of the publications contain letters which reflect the experience of users of Exide batteries in vehicles, and in all conditions of service. These booklets are sent free at request.

BIG PROSPECTS FOR CHICAGO TRUCK SHOW.

THE second section, or part II of the Chicago motor vehicle show, devoted to service wagons, which will be opened Feb. 10 and continue until the evening of Feb. 15, will be, in point of space occupied, larger than any similar exhibition ever held in the Windy City, and if the expectations of Manager S. A. Miles are realized the exposition will have a few more makes of vehicles than were displayed in the metropolitan show. The exhibition this year will take place in the Coliseum and Annex, the First Regiment armory and the Wilson building, the last mentioned structure being an overflow in which will be seen four exhibits. There has been keen anticipation by the industry as to the results from the Chicago show from the viewpoint of business transacted and relations established, for it is maintained that with the experience at New York there is every reason to believe that there will be quite as many desirous of engaging in the sale of service wagons at Chicago, and if this belief is well founded the representatives of the manufacturers will be very largely increased.

The possibilities are, no doubt, very large, but it is impossible to determine the development of new business, as measured by added representation, until the production of the industry can be estimated, and there are many who are willing to act conservatively, after making contract for the sale of their output, rather than to plan expansion on the basis of contracts made but not delivered. But there is reason to believe there will be at least as large, and perhaps larger, number visiting the show with a view of making agencies and who will be willing to make good sized orders if deliveries can be made within a reasonable length of time.

Probably one of the problems that is now confronting the manufacturers is that of filling the orders contracted for within the times fixed, and yet take care of the business that is promised. At New York some of the makers maintained that they would not then be able to produce more than 50 per cent. of the vehicles that they might sell if they had the production capacity, and as more than 75 per cent. of those that made display at New York will exhibit at Chicago, additional orders would mean refusal or a readjustment of factory facilities that will meet the demand.

According to the latest list of vehicle exhibitors, and which may be considered substantially correct, there will be in all 72 different firms represented at Chicago, but as two of these will show both electric and gasoline machines there may be said to be 74. This number is eight more than exhibited at New York, and of the Chicago exhibitors there will be 22 makers who did not show at the metropolis, although several of them engaged space and then decided to withdraw.

If the western national show is to be judged by number of exhibitors then it has the largest exhibition of the year, with a probability of being closely pushed by the Boston exposition. But whether or not there will be more machines shown cannot be determined until the doors have been opened. According to the latest statement of the management there will be 37 exhibitors at the Coliseum, 11 in the Coliseum Annex, 20 at the First Regiment armory and four at the Wilson building, while it is expected that the great majority of the displays of accessories, supplies, equipment and the like will be continued through the second week.

The exhibitors will be the following concerns: Coliseum, Adams Bros. Company, American Locomotive Company, Autocar Company, Buffalo Electric Vehicle Company, Buick Motor Company, Clark Delivery Car Company, Dayton Auto Truck Company, Durant-Dort Carriage Company, Federal Motor Truck Company, General Motors Truck Company, Garford Company, Gramm Motor Truck Company, Hupp Motor Car Company, International Motor Company, Thomas B. Jeffery Company, Kelly-Springfield Motor Truck Company, Kentucky Wagon Manufacturing Company, Kissel Motor Car Company, Knox Automobile Company, Krebs Commercial Car Company, Locomobile Company of America, Mais Motor Truck Company, Mercury Manufacturing Company, Old Reliable Motor Truck Company, Peerless Motor Car Company, Pierce-Arrow Motor Car Company, Pope Manufacturing Company, Reliance Motor Truck Company, Reo Motor Car Company, Selden Motor Vehicle Company, Speedwell Motor Car Company, Studebaker Corporation, Sternberg Manufacturing Company, U. S. Motor Truck Company, Velie Motor Vehicle Company, Walker Vehicle Company, Waverley Company; Coliseum Annex, Bowling Green Motor Car Company, Chase Motor Truck Company, Dart Manufacturing Company, Harder Auto Truck Company, H. J. Koehler Sporting Goods Company, Lippard-Stewart Motor Car Company, M. & P. Electric Vehicle Company, Service Motor Car Company, Standard Motor Truck Company, Transit Motor Truck Company, Inc., Universal Motor Truck Company; First Regiment armory, Avery Company, Baker Motor Vehicle Company, Bessemer Motor Truck Company, Brown Commercial Car Company, Chicago Pneumatic Tool Company, Commerce Motor Car Company, Four Wheel Drive Automobile Company, General Vehicle Company, Gramm-Bernstein Company, Harwood-Barley Manufacturing Company, International Harvester Company, Lauth-Juergens Motor Car Company, National Motor Truck Company, Mogul Motor Truck Company, Packard Motor Car Company, D. F. Poyer & Co., Sanford Motor Truck Company, Schacht Motor Car Company, A. O. Smith Company, White Company; Wilson building, O. Armleder & Co., Driggs-Seabury Ordnance Company, Grand Rapids Motor Truck Company, Randolph Motor Car Company.

Considering the list given above the following did not show at New York: Adams Bros. Company,

Avery Company, Buffalo Electric Vehicle Company, Harder Auto Truck Company, Thomas B. Jeffery Company, Kentucky Wagon Manufacturing Company, M. & P. Electric Vehicle Company, Mercury Manufacturing Company, Old Reliable Motor Truck Company, Reliance Motor Truck Company, Transit Motor Truck Company, Inc., U. S. Motor Truck Company, Walker Vehicle Company, Chicago Pneumatic Tool Company, Commerce Motor Car Company, Four Wheel Drive Automobile Company, National Motor Truck Company, Mogul Motor Truck Company, D. F. Poyer & Co., O. Armleder & Co., Randolph Motor Car Company.

Included in the exhibitors will be these manufacturers of electric vehicles: Baker Motor Vehicle Company, Buffalo Electric Vehicle Company, General Motors Truck Company, General Vehicle Company, Kentucky Wagon Manufacturing Company, M. & P. Electric Vehicle Company, Studebaker Corporation, Walker Vehicle Company, Waverley Company. Of these the Buffalo Electric Vehicle Company, Kentucky Wagon Manufacturing Company, M. & P. Electric Vehicle Company and the Walker Vehicle Company did not show at New York.

So far as the electric vehicle exhibitors are concerned they will not fare as well as they did at the metropolitan exhibition, where they were all located at Grand Central Palace, for they will be seen at both the Coliseum and the armory, and are scattered and not departmentalized.

The displays to be made of accessories, equipment, supplies, etc., will be very complete and it is probable they will be as numerous as at New York, but a distinct feature will be the special body equipment adapted for varying purposes and for facilitating loading and unloading. While many of the manufacturers will have these distinct types installed on their vehicles, some of the makers of bodies will make displays of designs that have been developed by them and which have qualities that recommend them to those who would secure the greatest economy through the operation of their equipment. In connection with these will be seen a number of hoisting dump bodies, operative by manual and motor power, in capacities ranging from one to seven tons.

There will be some attention given to tractors, for several of the manufacturers having displays have begun the production of these, and in the case of a number of others dead wagons have been adapted which may be used in varying forms of haulage. The greatest capacity of the tractors thus far exhibited is 12 tons, and this is a production that can be advantageously used in construction work. No specialization has been made of vehicles suitable for trailers, for there has been but little attention given to the development of this form of equipment.

BOSTON SHOW PROMISES BIG BUSINESS.

THE Boston show of service wagons, which will take place at Mechanics' building, Huntington avenue, March 19-26, will be an exhibition of national proportions which will, however, appeal to the business men of New England and adjacent states and provinces. The Boston shows have always been the opportunity of each year for the agents and representatives to contact with those who were desirous of buying, and for this reason have had all the productiveness of the local exhibition and the magnitude of the national exposition, a combination that must be considered ideal.

The service wagon market will be more active than ever before and with a realization of the demands it is expected that the manufacturers will co-operate with their representatives or agents to make the show the largest and best of the country. No statement has as yet been made by Manager Chester I. Campbell, but it is believed that there will be more makes and more vehicles and chassis shown than at any other show yet held.

The pleasure car show will be concluded March 15 and the building will be closed until the evening of March 19, when the industrial wagon exhibition will be opened. It will continue for six full days and an intervening Sunday. The interval between the shows will give ample time for the arrangement of the exhibits, and permit the exhibitors to rest after the activities of the first show.

The conditions in New England, where the commercial centres are frequent and the highways are exceptionally good, are unusually favorable for the use of the motor vehicle, and a recent statement of registration shows that approximately a seventh of the entire number of service wagons in the United States are owned in these states. With the remarkable interest in business economy, which has been very largely promoted by the educational campaigns for several years, it is believed that there will be a very material increase in vehicles for service, and it is not at all improbable that the total at the end of the year will show a gain in registration of upwards of 50 per cent. The influence of the Boston show in this market is very large and with a knowledge of the possibilities the exhibitors will make every endeavor to insure to themselves the benefits of its productiveness through fine exhibits and high class selling forces.

The Motor Wagon Company of Detroit has decided to add a half-ton truck to its models, having been manufacturing in the past an 800-pound delivery wagon with a two-cycle, two-cylinder engine. The new wagon will be constructed of standard parts and a four-cylinder, four-cycle motor will be utilized. The truck will have a three-speed gear of the selective type and a double side chain drive. The standard body will provide 22 square feet of loading space, the close bodies having 100 square feet of load capacity.

MOTOR TRUCK DELIVERY IN TWO STATES.

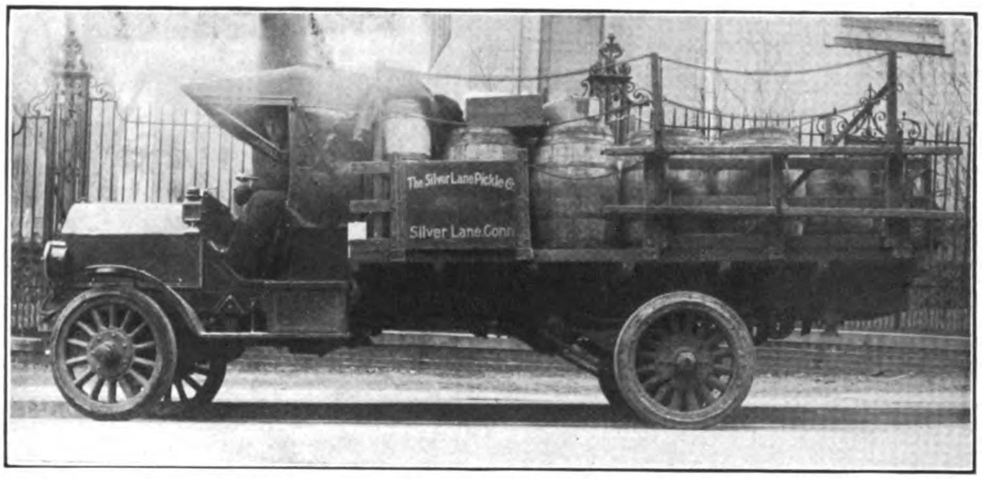
USING a motor truck instead of steam or electric railroad service to make delivery the Silver Lane Pickle Company, Silver Lane, Conn., has made a considerable saving in money and has distributed its products with much better satisfaction to its customers. As the company has owned the machine, a three-ton KisselKar, since last April, and has worked it under all conditions, its experience can be regarded as sufficient to base judgment on the possibilities through its use. The mileage up to the present time is between 8000 and 9000.

The factory of the company is between four and five miles from Hartford, and from this point distribution is made, and the vegetables from which the pickles are made are hauled from the farms in Vernon and Rockville, where about 58 acres of land are cultivated. During the harvesting season the work of the company is very largely increased, for the crops must be brought from the farms to the plant, and this haulage cannot be delayed because of the perishable nature of the vegetables, while at the same time the deliveries must be continued.

The business of the company has extended until it has customers in many of the cities of Connecticut and Massachusetts, and the barrels or other containers must be taken from the factory to the railroad freight station at Hartford or to the trolley freight station by the concern and shipped. The shipments are double tagged and on arrival at the destination are taken by local expressmen and delivered to the customers, who also collect the empty containers, bring them to the freight stations and ship them to the factory.

The business was carried on in this manner so far as deliveries was concerned, save in Hartford, until the company decided to buy the truck. Then as rapidly as plans could be made the machine was used for delivery in the Connecticut river valley as far north as Northampton, a distance of about 50 miles, as far south as New Haven, and to Bridgeport. The run to Bridgeport is the longest thus far made, and while the round trip is 108 miles, the incidental deliveries and collections will bring the mileage to approximately 120. It was found that the machine could be driven from Hartford to Northampton or Bridgeport, making deliveries en route, and return in a single day, and this made it possible to serve customers far better than could be done with any other service, and at the same time developing the business as no other character of attention could do.

To understand the value of this direct delivery it should be known that with the railroad service delays were not only frequent, but at times were of extreme and exasperating length. The packages when received at the destinations were not always promptly hauled, and customers often complained that they were seriously inconvenienced by the failure of orders to reach them in season to properly maintain their stocks. The trolley lines were more satisfactory than the steam railroads, but these were by no means ideal. An instance that well illustrates the conditions so far as railroad transportation are concerned happened when an order of sauer krout was shipped by freight from Hartford to Rockville, a distance of 14 miles, because the truck was not that day available for delivery. Eight days after the shipment a salesman called on the Rockville customer just as an expressman was delivering the order, which could have been sent out by the truck in less than two hours. There could be no more convincing contrast of the desirability of prompt delivery.



KisselKar Three-Ton Truck That Makes Quick Deliveries in Two States for the Silver Lane Pickle Company, Silver Lane, Conn.

The company does a large business with Worcester, Mass., firms, and it is intended the coming spring to send the truck to that city, a distance of about 90 miles, and this will be made a two-day run. The Bridgeport route will also be covered in two days, because the long drives mean hard work for the crew of the truck. Wherever the business will justify and within a radius of 100 miles the truck is to be used for delivery and collection.

The farms at Rockville and Vernon are very productive and last year more than 10,000,000 pickles were brought from them to the factory. The farms are two miles distant from the nearest trolley freight station and before the truck was used the vegetables were hauled to cars and from cars to the factory, necessitating several handlings that caused a considerable damage and loss. Last season the truck was used to haul the crops and it was used practically 24 hours daily during the harvest, two men manning it. It min-

imized handling and the time the crops were on the way, and in this manner worked a great saving, while there was the reduction of the haulage expense to a very large degree. F. C. Gould of the company says that during this period the truck earned more than $50 a day in excess of its operating cost, and this in addition to the economy in other ways.

Mr. Gould regards the truck as being a very wise investment. While it is not maintained there is a great saving in actual cost of freightage, there are many reasons why the machines should be used, but the elimination of breakage, the quick delivery and the better satisfied customers mean business development and cannot be measured by figures. The approximate cost of operating the truck is $12.50 a day, and the total is based on an estimate for a year as follows:

Interest at 5 per cent	$170.00
Insurance	131.00
Depreciation at 20 per cent	680.00
Wages, driver and helper	1456.00
Fuel, lubricants, etc	600.00
Repairs, 10 per cent	340.00
Tires, 10,000 miles guaranteed	250.00
Taxes	68.00
Total	$3695.00
Daily cost, 300 working days	$12.32

As the machine has been used for practically a year the figures given may be accepted as being very close to the actual expense, and not a result of theory. The company had some trouble with the tires used, and it was maintained by the representatives at the maker's branch office at Hartford that the truck was overloaded. An observer was placed on the machine and after investigation it was decided that the tires were overloaded, and not the truck. As a result of the inquiry five-inch dual tires were placed on the rear wheels, and it is believed that the condition has been successfully met.

The roads on which the machine is driven between the factory and Hartford are principally macadam, but better within the city than outside. The main highways are traversed generally and the streets of the cities, so there is no special operating condition. Mr. Gould has owned four Columbia cars and is now driving a machine of that make, and his knowledge of automobiles has been very useful in efficiently operating the truck. The garage is located at the plant at Silver Lane.

STUDEBAKER PLANS FOR 1913.

New Line of Gasoline and Electric Vehicles Will Give Purchasers Wide Range of Selection.

The Studebaker Corporation, Detroit, maker of Studebaker pleasure and commercial vehicles, will greatly increase its truck department for 1913 and will manufacture and market a complete line of gasoline and electrically propelled vehicles varying in size from light delivery wagons to heavy duty trucks. Four chassis types will cover a range from 1500 to 12,000 pounds. The Studebaker designs are by Albert F. Mais, who took charge of this department more than a year ago. During 1912 the company produced more motor driven commercial cars than ever before in its history and the output this year is expected to greatly exceed this.

The electric trucks have to a large extent been redesigned and one model is equipped with worm drive. At first Studebaker trucks will be sold in New York, Boston, Philadelphia, Chicago, Los Angeles and San Francisco through truck departments added to the respective branches, but the service will be greatly extended as soon as arrangements can be completed. The bodies will be built in the company's South Bend plant, where an experience of more than 50 years has developed definite knowledge of load distribution and carrying design.

SPEEDWELL INCREASES CAPITAL.

Adopts Plan Whereby Purchasers of Pleasure Cars May Select New Rotary Valve Motor.

The Speedwell Motor Car Company, Dayton, O., maker of Speedwell trucks and pleasure cars, has arranged a bond issue of $150,000, which has been subscribed. The proposition of increasing the capital stock of the company to $600,000 will be submitted to the stockholders. This bond issue was planned to take care of the extension of the Speedwell product involving the use of Mead rotary valve six-cylinder motors on a portion of the output of the factory.

After tests extending over two years the Speedwell company has taken a license under the Mead patents for the Mead rotary valve motor. While for some time foreign makers have offered the motor car buyer choice of poppet or non-poppet valve motors, the Speedwell company claims to be the pioneer in this country in equipping its cars at the customer's option with either type. The Speedwell car has a standard chassis and the cars will be alike except the power plant, which will be regulated according to the patron's pleasure. A limited number of Mead motors will be built the current season, while a larger output of this type is planned for next year.

REMOVES PLANT TO NEVADA.

Four Traction Auto Company Merges with Nevada Manufacturing Concern to Produce Kato Line.

The Four Traction Auto Company, Mankato, Minn., maker of Kato four-drive trucks, has made the announcement that it has combined with the Nevada Manufacturing Company, Nevada, Ia.

The Four Traction Auto Company has been very successful in the manufacture of its Kato trucks, which have been placed in service in all sections of the country. However, under the merger of the two concerns the company will move much of its equipment to Nevada, where the Kato trucks will in future be manufactured by the Nevada Manufacturing Company.

MOTOR EXPRESS WAGON WORK PROFITABLE.

THE value of a motor vehicle used in combination with horse equipment is seldom realized, and because of the practical results obtained with a one-ton General Vehicle wagon the experience of Downing & Perkins, Hartford, Conn., is of unusual interest. It is a demonstration of the possibilities of increasing business and economizing as well. The firm was established in 1830 and is one of the best known transportation contractors in the state. All its haulage was done with horses until June 10 of last year when the electric was started. With this machine the firm has converted the undesirable business, that which it could hardly afford to reject and from which little or no profit was realized, into profitable patronage.

The mileage capacity of the machine and that it can be worked as many hours as desired, are the principal factors, and while it is extremely useful for any kind of work it is especially productive in trips of considerable length. D. C. Perkins of the firm says that for two years motor vehicles were considered, and while he was not convinced that any machine would do his work satisfactorily, he bought the wagon because he simply had to have something better horses.

The machine was assigned to the long, hard hauls that tire out horses and a good deal of the work that is really special or emergency haulage. Mr. Perkins says that for two months after he started the electric he did not want to look at the books for he was almost certain the showing would be unsatisfactory. But to his surprise he found that June, July and August proved successively more productive. He had utilized it in the work where it would relieve the horses and improve his service, and the result was more than he expected.

He found that where he had to keep an extra horse for each two wagons used, this reserve was unnecessary with the wagon in operation. That when the animals were tired at the end of a day and it was abuse to drive them more, the work could be done with the machine, saving the animals and satisfying the customers.

Mr. Perkins instanced a morning's work. The wagon was sent to the freight yard, three-quarters of a mile from the office, where a load was taken and carried two miles to Chapin place and unloaded; there it took on another load and was driven to Charter Oak Park, three miles distant, unloaded at different points and after taking on a load of fencing was driven to New Britain, about six miles, and returned to the office, making at least 20 miles by 11 in the morning. To do this same work, horses would require at least 12 hours. In haulage speed is necessary to insure a profit and when horses are loaded to their capacity the work cannot be quickly done. He believes that as to efficiency the wagon is at least equal to three horses at their best. Recently the firm sent a heavy casting to Manchester and to do this work with horses a full day would have been required and the charge would have been $7.50, but the wagon made the round trip in a little more than two hours and traversed about 22 miles.

Mr. Perkins finds that besides the utility of the wagon at his command his horses do better work when used considerately. He regards the limitations of the wagon largely a matter of drivers, and when emergency work is needed it can be done. The Saturday before Christmas the wagon was driven 66 miles, being in regular work during the day and delivering mail at night. The following Monday the mileage was 60, and all of it in Hartford. The average work for the horse is 15 miles, and for the wagon from 35 to 40. The driver drove horses before he was given the wagon. Mr. Perkins says that from his experience the wagon is a good investment and that in all probability he will purchase another in the spring. He is not only satisfied with the wagon, but believes the machine is worth $1000 to him from the peace of mind it has afforded him.

He is intensely practical, and he maintains that it is more of a problem to teach the public how to use the motor wagon than to build it. He says that people generally refuse to consider the value of the time of others. Everywhere the machine is sent the driver is

One-Ton General Vehicle Wagon Used by Downing & Perkins, a Hartford, Conn., Transportation Contractor, with Much Success.

compelled to wait. These delays cause serious loss to the owners of automobiles. He cited an instance of where his driver had to wait 90 minutes to unload 12 barrels of sugar, and when he went into the store he had to move three or four loads left by other drivers. Not only this, the owner of the store would not sign for the sugar until it was all within the building.

In considering horse cost Mr. Perkins stated that it costs $5 a day to use a single animal and $6 a day for a two-horse team. Not only this, horse cost has been steadily increasing and the end is not yet. As to the expense of operating the wagon it is maintained that it must earn $2000 a year to be profitable. Between June 10 and Dec. 28 it had earned $1578, or approximately $10.50 a day. The cost of operating the wagon is fixed at $7.50 a day, and if the same ratio of earnings is to continue it will show a profit of $3 a day, and for 300 working days that is $900, or about 45 per cent. on the purchase price. The owners maintain that it will show 25 per cent net profit.

An estimate of the cost of operation is as follows:

Interest at 5 per cent	$101.25
Depreciation at 10 per cent	202.50
Upkeep and repairs at 10 per cent	202.50
Tires, guaranteed for 10,000 miles	175.00
Liability insurance	110.00
Taxes	40.50
Garage service	120.00
Battery service	252.00
Driver, wages	700.00
Total	$1903.75
Daily cost	$6.35

The firm does not keep the machine in its stable, but stores it in the garage of the Commercial Electric Vehicle Company in Main street, where it is washed. The battery is not owned by Downing & Perkins, but is rented from the Hartford Electric Light Company. This plan requires the payment of a service charge and a stated price for each mile a battery is used in a wagon or truck, but the greater the mileage the expense is relatively lessened. The battery may be changed as often as it is necessary and the machine may be used continuously when wanted.

TO PRODUCE HINDLEY WORMS.

Otis Elevator Transfers Its Interest in Their Manufacture to a Separate Corporation.

The designing and manufacturing of worm gearing of the Hindley type, which has been a branch of the business conducted by the Otis Elevator Company, Philadelphia, Penn., has been discontinued by that company as such and since Jan. 1 has been taken over by the Hindley Gear Company, a corporation organized under the laws of Pennsylvania.

The increase in this line of work has reached such proportions that the Otis Elevator Company's officials believe their customers would be better served by having a separate concern take care of it, particularly in view of the increased demand for this type in commercial vehicles.

AN APPRECIATION OF W. H. BLOOD, JR.

Electric Vehicle Association Honors Its First President by Complimentary Banquet.

An event of unusual pleasure to those present was the complimentary banquet tendered by the Electric Vehicle Association of America to the first president of that organization, W. H. Blood, Jr., of Boston, at Delmonico's, New York City, the evening of Jan. 16. The plans for the occasion were made to insure the presence of a large number of electric vehicle and central station men, and the company was in every way representative.

The toastmaster was Arthur Williams, who succeeded Mr. Blood as the executive of the association, and in proposing a toast to Mr. Blood he emphasized the admirable work of the guest of honor in developing the association. Mr. Blood in his response pointed out the influence of the organization and the possibilities for the future, stating that its membership now represented more than $500,000,000 capital, all directly interested in the utilization of electrical energy for light, power and heat. A number of letters and telegrams from prominent persons who were unable to be present were read.

There was abundant entertainment, both vocal and instrumental music, including several tenor solos by Thomas E. Murray, vice president and general manager of the New York Edison Company, and several professional entertainers added interest to the evening. The company included:

G. H. Atkin, W. H. Atkins, R. A. Bachman, E. W. M. Bailey, Day Baker, John H. Barker, H. H. Barnes, J. Crawford Bartlett, John J. Bartram, A. K. Baylor, Jos. F. Becker, W. G. Bee, Theodore Beran, Jean E. Blaise, Chas. Blizard, A. Bourquardez, Walter R. Boyd, Nicholas F. Brady, M. J. Brayton, C. H. Brennan, G. W. Brine, Geo. H. Buzby, J. H. Cafferty, F. N. Carle, E. A. Carolan, M. B. Chase, J. S. Codman, L. A. Coleman, Frederick G. Cooper, H. C. Cushing, Jr., E. W. Curtis, Jr., Robt. W. Daniels, H. L. Davisson, James C. DeLong, F. S. Dellenbaugh, Jr., Geo. Davies, Hayden Eames, C. L. Edgar, L. L. Edgar, Dudley Farrand, Henry C. Fling, W. H. Francis, W. W. Freeman, F. W. Frueauff, F. S. Gassaway, E. C. Geither, J. F. Gilchrist, Albert Goldman, E. W. Goldschmidt, J. H. Goehst, Uri B. Grannis, Emlen S. Hare, Geo. H. Harries, Henry R. Hayes, Geo. W. Hill, H. W. Hillman, Geo. W. Holden, W. E. Holland, Welles E. Holmes, S. B. Howard, J. T. Hutchings, Wm. Illch, W. H. Johnson, T. I. Jones, J. Kelly, Geo. H. Kelly, Wm. P. Kennedy, F. M. Kimball, G. G. Laird, J. M. Lansden, C. L. Law, J. W. Lieb, Jr., Arthur B. Lisle, C. A. Littlefield, R. McA. Lloyd, R. L. Lloyd, Ernest Lunn, Frank S. Marr, E. S. Mansfield, Hal Marchbanks, Converse D. Marsh, T. C. Martin, Arthur Miller, Jos. T. Maxwell, W. E. McCoy, W. D. McJunkin, C. E. Michel, John B. Miller, E. A. Mills, Jos. B. Murray, Thos. E. Murray, S. St. I. Morgan, C. A. Musselman, C. Nast, A. F. Neale, F. B. Neely, Walter Neumuller, E. A. Norman, R. C. Norton, W. H. Onken, Jr., R. F. Pack, Geo. F. Parker, Wm. H. Patton, F. F. Phillips, Chas. W. Price, E. L. Reynolds, H. H. Rice, Jesse Richards, Harvey Robinson, E. J. Ross, Jr., Robt. E. Russell, H. T. Sands, F. F. Sampson, Robt. M. Searle, Chas. S. Shepard, M. A. Singer, Frank W. Smith, H. H. Smith, C. W. Squires, Jr., W. G. Stetson, Chas. W. Stone, Frank J. Stone, W. B. Stoughton, Dan Swander, F. M. Tait, Albert Taylor, C. I. Taylor, A. B. Tenney, C. G. M. Thomas, S. G. Thompson, H. F. Thomson, W. G. Tucker, Jr., E. F. Tweedy, P. D. Wagoner, J. M. Wakeman, L. R. Wallis, C. A. Ward, C. E. Watrous, W. F. Wells, G. W. Wesley, F. R. White, W. H. Whitton, C. L. F. Wieber, Arthur Williams, Edward T. Williams, Hugh M. Wilson, O. D. Young, P. S. Young, R. R. Young.

The Alco truck that recently made the transcontinental run was driven from Philadelphia to New York Jan. 16, carrying 30 boxes of soap, in eight hours and 31 minutes, this being 14 minutes less than the trip had been made by a service wagon.

MILLER PROPOSES SUMMER TRUCK SHOWS.

THE suggestion is made by Charles E. Miller of New York, who is the largest as well as the pioneer accessory and supply dealer of America, who was one of the committee that arranged the first motor vehicle exhibition for New York, that the show of service vehicles should be made during the summer of early autumn, and that it should take place where demonstrations can be made.

While Mr. Miller has made no outline of his proposal it has every quality to recommend it to the serious attention of all makers of vehicles built for freight transportation, and in line with the suggestion is the assumption that the place for exhibition should be where there will be a suitable enclosure and sufficient area for demonstrating. This would seemingly require a place such as might be found within a trotting park, an agricultural ground, or, possibly, within a speedway, where a track might be available for operation of the vehicles at different times, and where there could be trials of different kinds that would be of an educational character.

In connection with this it would be possible to demonstrate the practical use of all forms of body equipment, the possibilities of quick loading and unloading bodies, the economies of special loading facilities, and the practical results to be obtained from governing devices and other forms of control, the efficiency of brakes and such other qualities as are regarded as essential.

It is not to be assumed that one exhibition of this character would suffice for the United States, but it is certain enough that such a number as would be justified by conditions could be arranged. So far as accessories and the like are concerned it has been very effectively demonstrated that the volume of business transacted during the showing of service wagons is not sufficient to warrant any great anxiety on the part of those who manufacture or distribute them.

Considered from the practical point of view such an exhibition should logically be held in the summer or autumn, but it might be said that the time could be determined with reference to the climatic conditions rather than to specific dates. For instance, if held in different parts of the country, it might be possible to arrange a series of such exhibitions, and, if desirable, travel could be made by road instead of by railroad. To be sure there would be no ornate surroundings and nothing to attract the eye, but the setting of a business man's show could well be bare walls or fences if the merits of the exhibits were such as to interest.

FISK TIRE COMPANY AFFAIRS.

Reorganization as Massachusetts Corporation with Capital of $15,000,000—Willys Purchases Stock.

John N. Willys, president of the Willys-Overland Company, Detroit, maker of Overland cars, and who controls an interest in several pleasure and commercial vehicle concerns, including the Gramm Motor Truck Company and the Garford Company, has purchased an interest in the Fisk Rubber Company, Chicopee Falls, Mass., maker of Fisk tires, according to a recent announcement. It is also stated that Mr. Willys' purchase is merely in the nature of an investment in a substantial concern and he will take no active part in its management, or become an officer or director of the firm.

Harry T. Dunn, president of the Fisk Rubber Company, has issued a statement to the effect that he and Harry G. Fisk, secretary-treasurer of the company, will materially increase their holdings and will remain in full charge of the concern, which will retain its individuality. It is also stated that the Fisk company is a Delaware corporation, but a Massachusetts corporation is in process of organization and practically completed, with an authorized capital of $15,000,000, of which $5,000,000 is first preferred stock, $3,000,000 of which will be issued; $2,000,000 second preferred and $8,000,000 common. The Massachusetts corporation will acquire all of the assets of the Delaware concern in the immediate future. The Massachusetts Fisk Rubber Company's active management will be identical with the present management of the Delaware concern.

WANT MOTOR TRUCK CONTEST.

Two National Associations Considering Plans for Holding Reliability Run and Open Air Show.

At the recent meeting of the American Automobile Association at New York City, formal notice was given the agitation for an annual reliability event for motor trucks, said to have had its inception at Detroit. The question was brought forward in the form of a resolution, which was adopted, authorizing the president to appoint a committee to discuss the matter with the National Association of Automobile Manufacturers, and if sufficient support in the form of a representative entry list is forthcoming the president is further empowered to appoint a committee and otherwise arrange for such an event during the coming summer.

The form of contest to be recommended is not known, but William E. Metzger, a member of the American Automobile Association's executive committee and president of the National Association of Automobile Manufacturers, favored the application which was made for a national non-stop run to be conducted at Detroit at the time of the Michigan state fair, with an open air motor truck exhibition to be held on the state fair grounds.

PUBLISHED THE FIRST OF EACH MONTH.

SUBSCRIPTIONS:
The United States and Mexico, the year, $1 in advance; Canada and Foreign Countries in Postal Union, the year, $2 in advance. Fifteen cents the copy.

ADVERTISING RATES.
Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.
Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.
Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

COST OF MOTOR FUEL.

A great deal of concern has been manifested in the cost of fuel for explosive vehicle engines. The price of gasoline has increased very much within a comparatively short time. There is a limit to the production unless markets can be found for the other products from refining crude mineral oils, and the supply establishes the market prices. Other fuels are available, but they are not practical with the present types of carburetors.

Kerosene is a logical substitute and the only reason that militates against its use is the difficulty of initial carburetion. Kerosene will vaporize with agitation at 90 degrees, and starting is easy at 100 degrees of temperature. Heating a carburetor to afford vaporization is one possibility and starting with gasoline and changing to kerosene, is another, using the types of carburetors and engines now the vogue.

Alcohol is a practical fuel with differently designed engines and carburetors. While alcohol is now more expensive than either kerosene or gasoline, this is because there has been so little demand for it. Alcohol requires a higher compression motor with the accompanying results from such construction.

Kerosene, however, will be for a long period a cheap and certain fuel. The manufacturers of carburetors, engines, vehicles and producers of kerosene have the same interest in practically utilizing it, and the time to perfect carburetion is now.

PROGRESS IN TRUCK BUILDING.

Examination of the service wagons exhibited at the New York display impressed upon observers that the engineers and manufacturers have given great attention to perfection of existing models to insure endurance and longevity. With the majority of the builders the purpose has been to increase the strength and proportions of members to resist the usual causes of deterioration, for there has been keen realization that constructions intended for fast haulage are subject to excessive road stresses, especially when driven light. The improvement of the machines does not mean radical changes, but to the contrary there has been a careful development of designs to meet the requirements evident through experience and continued observation.

The makers of heavy vehicles have generally perfected body equipment with a view of facilitating loading and unloading, while the builders of the smaller types have thus far apparently relied upon speed as being the main factor in economic work. One thing especially noticeable was the increased accessibility of the mechanisms, and the adaptations to minimize labor for care and maintenance and to reduce the time that a vehicle need be withdrawn from service for repair or overhaul.

LIMITING VEHICLE WEIGHT.

The bill limiting the weight of motor trucks, the loads that can be carried by them and the sizes of tires, which was last year referred by the Massachusetts legislature to this year's session of that body, has been sponsored by the state highway commission. One of the reasons given by those favoring its passage is the general character of the bridges of the main highways outside of the cities, and another is the destructive effects of motor vehicle traffic on the roads.

The motor vehicle owners and users of Massachusetts paid to the state in fees of different kinds last year considerably in excess of $600,000, the greater part of which was applied to the use of the highway commission, and this in addition to the regular taxes.

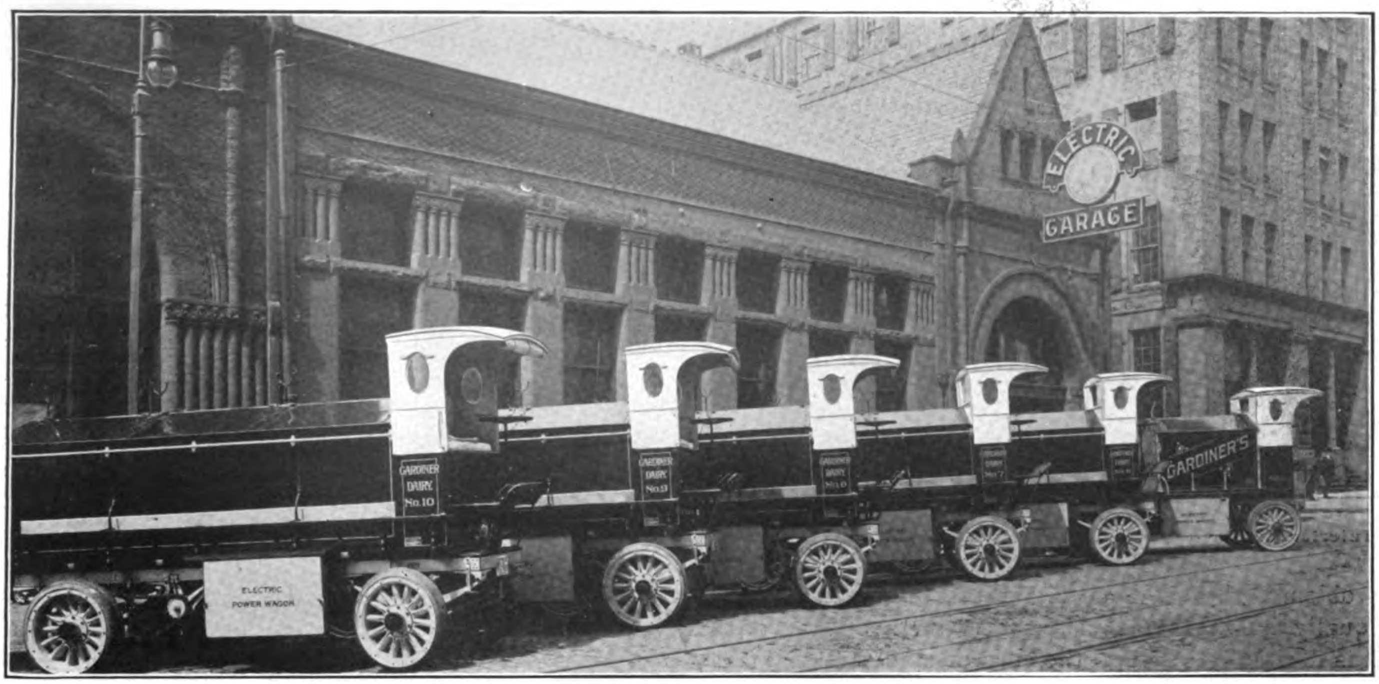
The highway commission is willing to advocate what will lessen the taxes in the towns, and especially benefit the town residents. It now proposes to go even further and to insure the towns against such bridge improvements as might be necessary eventually to meet the demands of highway vehicles. As the chief value of the motor freight vehicle is its increased load capacity, and its speed seldom if ever reaches the rate at which the most radical can assume roads are worn abnormally, the highway commission of Massachusetts seemingly proposes to legislate from the business interests of the state practically all the economies possible in haulage by restricting the use of motor trucks.

CENTRAL STATION PUBLIC GARAGE.

Consolidated Gas Electric Light and Power Company, Baltimore, Md., Has Organization for Selling, and Facilities for Maintaining Vehicles That It Sells, and Systematically Promotes the Use of Electric Wagons.

By William W. Scott.

THE attitude of the central station—that is, the public service corporation supplying electric energy for power, light and heating—has a vast influence in the promotion of the use of the electric vehicle for service and for pleasure. It is a fact that the interests of the central stations, the wagon and car manufacturers and distributors, and the owners and users of machines are so interwoven that it is only through the intelligent co-operation of all these that the fullest measure of promotive endeavor may be realized. There will be no issue taken with the statement that the central station is the most important of all factors in the development of highway haulage, and that there will be results proportionate to the activity of the managements and their willingness to co-operate, because it is certain that only through the actual knowledge of the extent of this co-operation will those who can use electric vehicles decide upon them.



Exterior of the Garage of the Consolidated Gas Electric Light & Power Company, 30 South Eutaw Street, Baltimore, Md.

Wherever a central station is in operation, and there are close to 30,000 of them in America, electric energy is produced commercially, and its use is promoted. The electric vehicle affords a distinct market for energy of such importance that it must impel attention. But it is obvious that this source of revenue will only be what the central stations will make it. It would be possible for the owner of a machine to install his own charging plant and produce the current he would use, but this would entail investment, care, maintenance, and would involve his engaging in another enterprise that would be foreign to his business, unless it were necessary for him to create power. Where there is one person who might feel justified in installing a plant of this kind there are hundreds who would not, and it is evident that such installations would not affect the revenues of the central stations.

The concerns who are large producers of power would undoubtedly establish their own plants and such as these could not be regarded as prospective consumers of energy, but those who utilize current for lighting and power can be logically considered the prospects for business, provided they have use for delivery service. There is no question of the economic possibilities of the electric vehicle for innumerable purposes. The central station is usually located advantageously for the distribution of current, often in the centre of the business section of the community which is served, and there is but little construction or expense necessary in the extension of the mains or lines for supplying a public or private garage. There is reason to assume that any central station will make whatever extension of its lines is necessary when a customer is assured, and will encourage business that will insure a constant and a satisfactory revenue.

For a number of years, especially in the centres of population, the central stations have devoted much time and endeavor, generally with carefully consid-

ered system, toward the promotion of the use of current, and have encouraged household consumption. It has been necessary to have station equipment to supply the heaviest demand of the day, with a reasonable reserve production to meet exigencies, and the period or moment when the largest volume of energy is consumed is known as the "peak" of the "load." Naturally the "load" varies considerably, and is ordinarily smallest between midnight and the early morning hours, probably from 12 to 7 daily. The problem with practically all stations is to increase the consumption of energy when it can best be supplied, and to develop the use of current during the "off-peak" period.

Power consumption is generally during the working hours of the day, and the lighting load varies according to the season of the year, so that while power requirements and lighting service can be fairly accurately determined, there is a variance of the demands upon the central station. To equalize the consumption is the problem with every central station, and is regarded as equally important as increasing it. In other words, it is desirable to sell all the current made and to make as much as is possible. The central stations have generally organizations for promoting the sale of power and lighting, and in many cases for the development of household consumption. The production of energy for electric vehicles has presented very large possibilities, and it is with this—at least the commercial aspect—that this article has to do.

Interior of the Consolidated Gas Electric Light & Power Company's Garage from Near the Office Door.

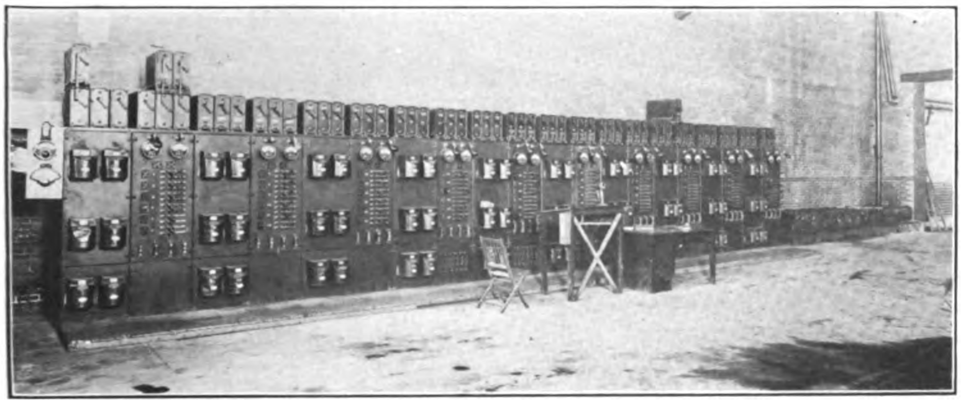
The electric service wagon is used, with comparatively few exceptions, by day. It is not unreasonable to assume that from 6 in the morning to 8 in the evening will cover the ordinary period of use of at least 95 per cent. of all business vehicles. Probably the time from 7 to 6 will include 80 per cent. of all, so that a comparatively small number would be worked earlier or later than the hours named. Between 6 in the evening and 7 in the morning the power load is relatively low, and the consumption for lighting is largest from dusk to 11 at night, leaving the time from 11 until 6 or 7 in the morning, when the load is the lowest. These statements are well enough known to the managements of the central stations, and the facts may differ somewhat in each community, but the proposition as it is presented is intended to inform those who may not be familiar with central station problems.

The central station has need for its own transportation service, this including fuel, material, construction work, maintenance work, as well as the distribution of supplies used by its customers. Thousands of stations today are using horses, and several hundred have installed electric wagons. Those having motor vehicles have found it economical to establish their own garages, where the machines may be charged and given the care and maintenance necessary. Several have established public stations in connection with their garages and are offering to the public the same service given to their own vehicles.

There are those who will maintain that the central station cannot be expected to engage in a public garage business, and that it is an undertaking for the individual who can specialize in this work, but there are innumerable reasons why this assertion is not well founded—at least as is the conduct of a garage for the care of gasoline vehicles. Those who have had the longest experience with garages for electric service wagons maintain that it is more economical for the man who owns less than a dozen machines to patronize the public station, because of the comparatively few men necessary to give the service. That is to say, that the same number of men required to care for and maintain 12 vehicles could, under normal conditions, give equally good attention to 50, and that the larger the number of wagons in a station the actual expense a wagon is relatively less.

Assuming that the central station finds it necessary to establish its own garage, it would be possible to serve the public to a standard that could not be given by the individual enterprise, and the patronage that could be developed would be more productive of revenue as it was developed. That is, it would require a stated expense to garage and care for its own service, and there would be a revenue that would be the more profitable as the number of machines increased. It is fair to assume that any central station would insist upon a satisfactory and economical upkeep of its equipment, and this would be the character of attention that would attract and impel the patronage of others.

The central station has numerous reasons to utilize electric vehicles. First of all it must have suf-



The Charging Board of the Garage, Which Will Charge 60 Batteries Simultaneously.

the radius of their movement, and they have sufficient speed to meet practically all requirements. There are possibilities of other forms of vehicles being the better adapted to certain works, but this is far from being the rule.

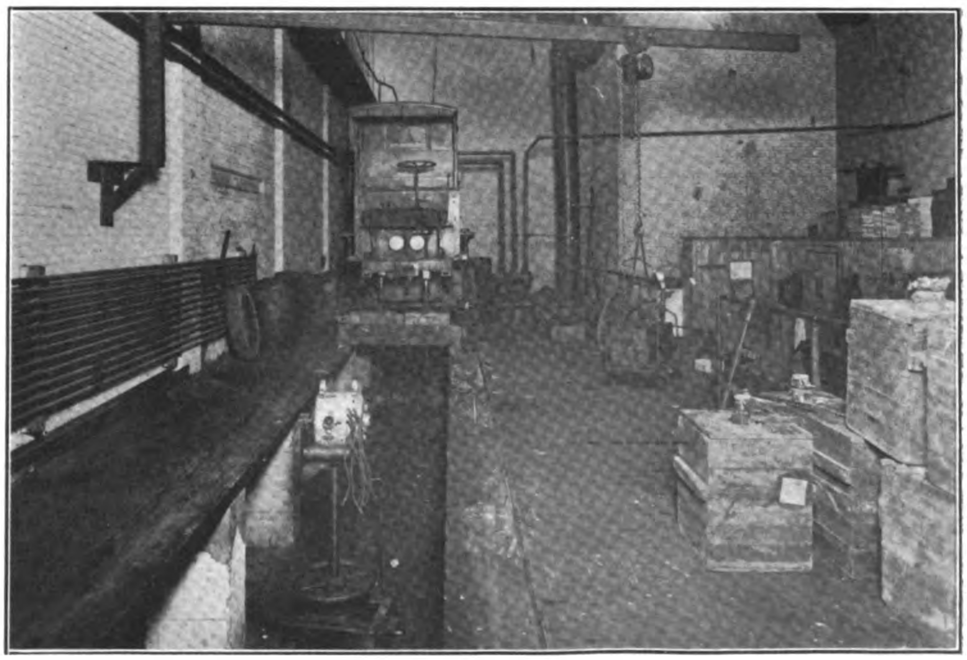
It is certain enough that the central station can and does develop its business. Many have splendid organizations that are constantly developing every possibility commercially. There is probably not one that would refuse consideration of an order from the owner of a single vehicle for current. Every encouragement would be given this character of business. To afford such service would entail more or less expense for construction and the owner would have to install the necessary equipment. With reference to the pleasure vehicle the private garage is often desired by the individual, but with service wagons, requiring daily charging and systematic attention, there is no doubt that a public electric station can better and more economically serve the owner than can any small organization he can establish.

To illustrate: The business man considering the purchase of electric vehicles desires to avail himself of their fullest economy. He may have what will serve as a garage, but to charge the batteries he will have to install equipment that should only be handled by a competent man. To use two or three machines would require as complete an organization as would be needed to use a score. He can obtain such a service at a public station at a really smaller expense, or perhaps a better service at no greater expense. The public electric garages are comparatively few, and the

ficient transportation, it can economically employ machines as against animals, it can secure a considerable advertising service through them, it can use its own energy at minimum expense, it can improve its service so far as construction and maintenance works are concerned, it must have available men who can be trusted with some of the work and it is not necessary to greatly augment the number of employees, it has facilities that can be used for maintaining its vehicles, it has organization that can satisfactorily supervise the service without increased expense, it has no necessity for increasing the overhead expenditures, and in addition to these it may be pointed out that there is a possibility of devoting its endeavors systematically to the promotion of the use of machines by others, increasing the consumption of current and supplying energy at a time of the day when it will really cost the least.

The sale of current during the "off-peak" period for electric vehicle charging really covers the greater part of the night for machines that are used for business by day. The average battery may be fully charged in approximately seven hours, but it is not always necessary to use the full charge, though it is best to charge and discharge it as completely as this may be done. The time of charging may be adapted to that part of the night when it can best be done, so long as the machines shall be in readiness for service when needed. By this is meant that it is not necessary to begin charging at any stated time, as with lighting or with power service. With the private garage or the public station, however, charging is usually begun early in the evening, as quickly as the vehicles are available, but this custom is not necessarily followed in the central station garage.

Relative to the utilization of electric machines by the central station it may be pointed out that for the lighting and power service, with rare exceptions, all of the work is within



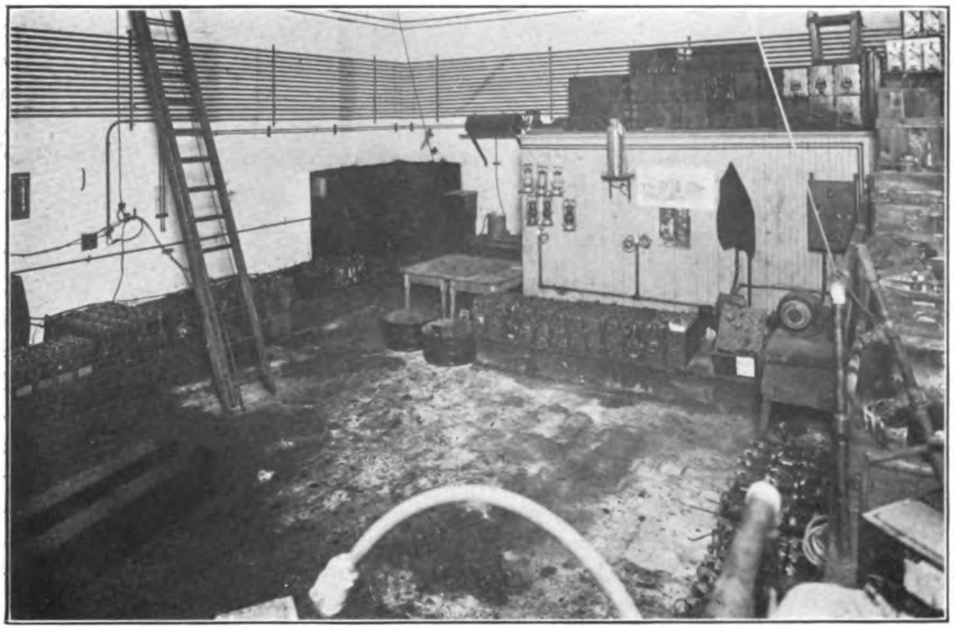
Repair Shop, Showing the Pit Under the Wooden Floor That Will Take Five Wagons, the Motor Jack and the Derrick for Handling Batteries and Heavy Weights.

general garages that afford electric vehicle service are not common. The man who utilizes electric machines must either provide his own facilities for caring for and maintaining them or accept what may be indifferent or inadequate service. But were it possible for him to rely upon the central station for a satisfactory garage service, such as could be maintained for the vehicular equipment of the station, this would bring about a condition that would undoubtedly promote the use of electric machines and insure the sale of current at a period when it could be most advantageously furnished.

The number of electric vehicles that will be sold undoubtedly will be greatly influenced by the attitude of the central stations, because many men will regard the service possibilities as being largely dependent upon the co-operation they shall receive from the stations. In fact they may be consistently regarded as the principal factor in promotion of electric wagon use and, as viewed by the public, are to benefit directly through the sale of current. That eventually there will be electric garages, or garages that will afford service for all classes of machines, there is no doubt, but the individuals who will establish such stations without co-operation from the central station and without sufficient prospective customers to justify such enterprises are far from numerous. Stated in another way, the central station can maintain a garage in connection with its own service and stimulate the use of machines and the sale of current, which ought to be a no inconsequential source of revenue.

A striking example of the possibilities of this cooperation and the results accomplished through a public service afforded at its garage is the development of electric vehicle use in Baltimore, Md., where the Consolidated Gas Electric Light & Power Company has inaugurated a systematic campaign of general promotion. The company has taken up the electric vehicle as a means for insuring the sale of current and has by progressive methods achieved a large measure of success. The company has formulated a policy that is in keeping with its progressiveness, and it has the agency of the General Vehicle Company for that city and vicinity. That is, the company has realized the need of stimulative and promotive endeavors and has organized a division that is devoted not only to the sale of vehicles, but it is affording a service that will make it possible for the man who owns a single machine to operate it at the same relative economy as the concern that possesses a large number.

The commercial department of the company is devoted to the promotion of the sale of electric energy for varying purposes, and included in this is the agency for the vehicles and the administration of the garage. The garage is at 30 South Eutaw street, where service is given for 48 machines aside from the company's electric transportation equipment. The company uses 21 machines and has three more ordered which will shortly be delivered. Two years ago the company had no electric vehicles and it was decided to utilize a number, the first order being for six. This necessitated the inauguration of an electric garage. The possibilities of an agency for machines were considered and believed to be such as to justify the company adding this to its regular business. The value of a public garage for the people who were regarded prospective purchasers and customers was realized and this was provided and was opened for business July 1, 1911.



Battery Room, Included with the Repair Shop, and Its Facilities for Restoration and Charging.

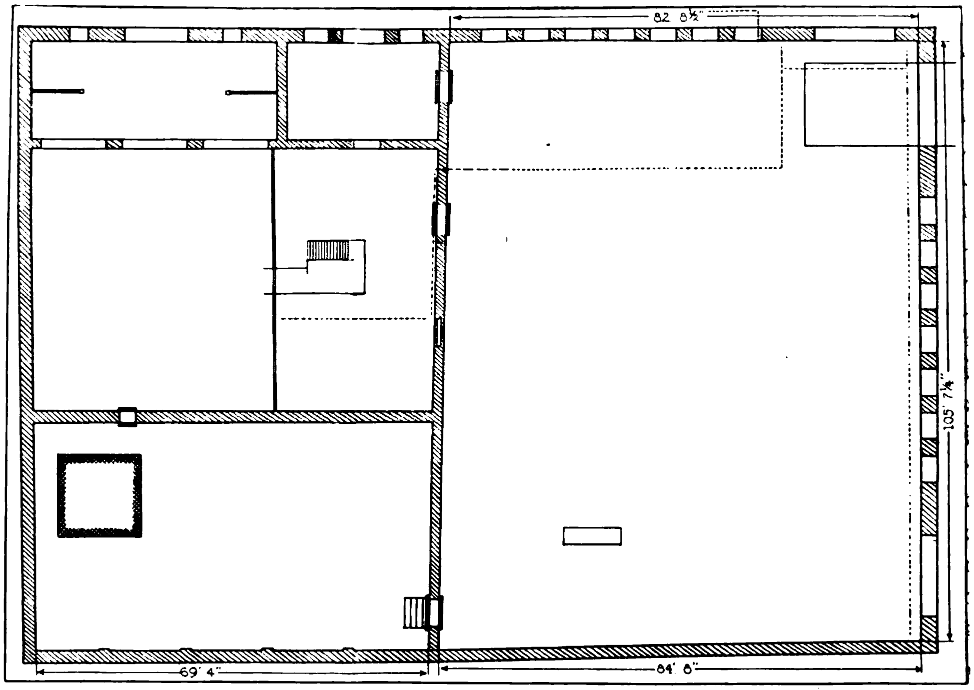
In establishing a garage provision was made for storing and serving about 100 machines, and a power house was turned over to the department by the company. This has a frontage of practically 108 feet and a depth of 157 feet, the power room affording a floor space 105 feet 7.25 inches by 84 feet 9 inches, with abundant light from the front. Over this is a pitch roof supported by trusses, so that the floor is unobstructed. At the rear of this is a heavy brick wall and through this what was the boiler room is entered. This is 69 feet four inches by 32 feet, in which is a chimney stack, and is now a repair shop and battery room. At the other side of the building is a room 27 feet two inches by 17 feet five inches, that is used as an office. The remainder of the structure is used for other purposes, but it is available in the event of need for expansion.

The boiler room floor is considerably below the level of the garage and so a floor or deck was laid over about half the area, this leaving the lower por-

tion for a battery room. An open space four feet wide was left in the floor close to the side wall, and this serves as a pit, as four or five machines can be run over it and worked on with perfect freedom and abundant light. The entrance to the garage is through a wide doorway by a run and the entire floor is concreted and is arranged so that it will drain when flushed. The charging panel or board, which will permit charging 60 batteries simultaneously, extends along the end wall farthest from the entrance. At either side of the garage proper is a concrete barrier which will prevent a vehicle being driven or backed against a wall, and insures sufficient space between the machines and the walls for work to be done. The charging mains extend along these walls and from them at frequent intervals leads and receptacles are provided. Convenient to the main entrance is the washstand, which will take three machines at one time. In several parts of the main floor are fire plugs, so that there is more than the usual fire protection. The building itself is practically fireproof, the walls being of brick and stone, with roof of tile set into steel frames and supported by the truss work. Practically the only thing about the structure that may be burned is the wooden framed window sash. There are fireproof doors between the garage and the battery room and repair shop, and in this section is the wooden deck or flooring, the wooden stock room, the benches and a closet or two. Were a fire to originate in this part of the garage it could not possibly do damage outside of it, and with the usually complete fire protection there is very little probability of loss from this cause.

The description of this garage has been given with the purpose of showing the policy of the company. The station is not in any sense cheap, nor is it a temporary proposition. There is surely not an electric garage in America that is better equipped and there is not one of greater capacity under a single roof. With reference to fire protection it is in a class by itself. Not only this, the building is modern and it will serve for a long period of years. There is possibility of expansion by taking over the remainder of the ground floor, which would probably accommodate about 60 machines, while it would be possible to construct a second floor that would probably afford space for as many more. So with comparatively small expense the company is in a position to provide service for from 225 to 250 machines in all, or about three times the number it now garages. This possibility of expansion is a very important factor and it will be seen that this increase of service can be provided without largely increased rental or additional taxation, while the nature of the building makes possible the minimum of insurance.

Having decided to establish the station the company selected what will insure every element of protection and safety as well as the care and attention. It is almost needless to say the equipment is equally high grade. While it is not necessary to have a large machine shop, with the regular facilities of the company open to it, the battery room, for instance, is fitted with a small motor generator for charging ignition batteries and series of vehicle battery cells, besides the regular charging leads and receptacles; and there are ample facilities for washing, testing, building and repairing batteries. In the repair pit is a motor jack on wheels, so that a motor may be taken from a chassis, lowered and moved as desired, while a derrick with a swinging arm and variable chain hoist is



Plan of the Electric Garage of the Consolidated Gas Electric Light & Power Company, 30 South Eutaw Street, Baltimore, Md.

mounted on the wall and adapted for innumerable purposes. Batteries are removed from the machines in the main floor and taken into the battery room on trucks, and are lifted and swung from the floor to any desired position. This facilitates handling and saves much labor. A glance at the accompanying illustration will show the repair pit, the motor jack and the derrick, and some of the uses made of them.

In considering the sales agency and garage department of this company it is proposed to follow sequentially the sale and use of vehicles, giving the forms of records used and the organization that is necessary to afford the service the company has established. The department is under the management of Douglass Burnett, executive of the commercial department, and the garage is managed by Harrison W. Wagner, who is assisted by a salesman in the agency department. These two men devote themselves to the exploitation

DRIVER'S REPORT.

Driver's Report, on Card Five by Three Inches, Ruled for 10 Lines and a Heading.

of the machines, Mr. Wagner giving whatever time is necessary to the supervision of the garage.

The sale of an electric vehicle is consummated by the acceptance by a purchaser of a proposal, which is made on a regular form, this requiring the delivery f. o. b. at Long Island City, N. Y., of a specified chassis and body, the terms being the payment of 25 per cent. upon execution of the contract and the remainder upon delivery. The vehicles are sold under the standard warranty of the manufacturer, but the company, acting as sales agent for the General Vehicle Company, guarantees to protect the purchaser under the warranty and on its own behalf, independently of the General Vehicle Company, and agrees to maintain in good running order for a period of one year from date of purchase the batteries and motors of all vehicles kept at the company's garage and operated normally according to the company's instructions. But the company does not accept any responsibility in connection with any vehicles when they have been altered or repaired outside of the company's garage, in cases where the machines are kept at the company's garage. It is also stipulated that when experts are furnished by the company for instruction purposes, they shall, while so employed, act solely at the risk and as agents of the purchaser. There are clauses which specify the company shall not be liable for consequential damage and for delays beyond the reasonable control of the company, and that the proposal is not binding unless accepted within 15 days of submission. There is also a provision that the proposal constitutes in all respects the agreement between the parties and no modification shall be binding unless it shall be executed by the purchaser and approved by the company.

The purchase having been made the garage service of the company is open to the purchaser under yearly contract. This contract states the following prices for the differing types of vehicles:

Capacity, Vehicles of General Vehicle Co.	Battery, No. of Plates a Cell.	Storage, Washing, Oiling, Inspection.	Monthly Charge for Current for Charging Each Battery.	Current for Charging Each Spare Battery.	Extra Battery Charging an Hour for Extra Charges to Make Additional Mileage.
700 lbs.	9 G. V.	$15	$10	$10	10c
1,000 lbs.	11 G. V.	18	12	10	12c
2,000 lbs.	15 G. V.	22	14	10	14c
4,000 lbs.	17 G. V.	26	19	10	19c
7,000 lbs.	21 G. V.	30	29	10	29c
10,000 lbs.	25 G. V.	30	29	10	29c

For repairs it is stipulated that an extra price will be made for all repair labor and material, according to the work done and the supplies furnished, except such maintenance of batteries and motors as may be furnished without extra charge under the contract covering the sale of the wagons.

The company will store, wash, oil and inspect electric power wagons sold by it and manufactured by the General Vehicle Company, and any extra batteries used with them, as listed above, and will furnish the electric charging of the machines. It will furnish electric current and will charge each battery in each wagon after the return from the day's work, using due diligence to make full charges, it being understood that at least eight hours is required for a full charge, according to the prices given. The company will furnish extra battery charges for additional mileage within any 24 hours at notice from the customer or his driver at the prices stated, the current to be supplied at not to exceed twice the normal charging rate (it being stated that each hour's charge so given should add about 20 per cent. to the day's mileage). The company agrees to furnish competent attendants and supervision over the operation and maintenance of the batteries and wagons while at the company's garage. It will also keep on file at its garage records of the mileage, charging current and inspections of all vehicles kept at its garage, which records are open to inspection by the owners of such vehicles. The company specifies that it does not insure the vehicles of

customers, that it shall not be liable for any loss, damage, or expense occasioned by its failure to supply electric current for any cause save willful neglect or default; that it shall not be liable for consequential damage, and that from the failure of the customer to comply with the provisions of the contract, or terms or conditions, or default of payment for service beyond 30 days, it may discontinue the service without incurring liability for any loss or damage. The contract specifies the number of vehicles and extra batteries to be cared for, and service is begun at noon of a given day and continues for a year, the bills to be payable monthly 10 days after rendition, and are to be sent to a stated address. When the service specified by the contract has been used for more than a year the contract may be terminated in 10 days by written notice from either contractor. The contract is not modified unless such modification is in writing and attached thereto.

The contract has been dealt with to considerable length from the fact that it calls for a year's service, and after that time it may be continued an indefinite period, terminable at 10 days' notice. This differs from the usual custom of garages, which is generally a monthly rate and for no stated period. While the charge for current is, according to the contract, a flat rate for a given capacity of vehicle, the American Express Company, which keeps its fleet of 25 machines at the garage, pays for the current used on the basis of kilowatt-hours, for which a charge is made of four cents a kilowatt. It will be seen, however, that under the contract the company will fully charge the batteries after each day's use.

The service of the garage is standard and it is admirably systematized. The organization includes Manager Harrison W. Wagner, his assistant in the sales department, a clerk, a garage foreman, day and night switchboard men, head battery man, assistant battery man and two helpers; three men who water batteries and oil and grease the wagons, day mechanic and helper, night mechanic and helper, two washers and a porter. The day "crew," outside of the office, consists of a foreman, switchboard man, battery man, assistant batteryman, mechanic and helper, and a battery man who works from 2 in the afternoon until 11 at night; the night "crew" includes a switchboard man, battery man, mechanic and helper, the helpers who water batteries and oil and grease, and two washers.

In the contract of sale of vehicles the company undertakes to give attention to the batteries and motors for a period of a year, and to insure the care necessary in charging what is known as a battery charging sheet is posted in the garage. This specifies the vehicles kept at the garage and the size and type of the batteries and the charging rate for each. It is necessary that this instruction be followed implicitly, and the order is signed by the garage manager and approved by the manager of the commercial department. A copy of this sheet is of interest:

and approved by the manager of the commercial department. This is not to be varied from under any conditions without the sanction of both garage and department heads. The expectation is to insure a uniform service with reference to the batteries. The methods of the company are thorough and have been carefully developed.

In describing the service of the garage it should be stated that the care and attention do not differ, no matter what the vehicle, although there is of necessity a variance in the character of record, because, in the case of the American Express Company, additional reports are required by that concern. When the contract has been made and the machine is in use each driver is required to make out a report on the "Driver's Report" card, this stating the number of the wagon, the date, the time of leaving and returning to the garage, the odometer reading for the morning and afternoon work, and a brief report on the condition of the machine, this indicating any attention that may, in the judgment of the driver, be required. This is signed and deposited at the garage office. All these cards are examined by the garage foreman, who determines the repairs or adjustments, if any, and from the mileage whatever instruction may be desired with reference to charging.

That there may be no possibility of error all of the orders for repairing, adjusting and special charging instructions are noted on a "Daily Repair and Charging Instruction Sheet" and this is posted in the garage. This gives the number of the wagon, the nature of the repair or the charging direction, and when either or both attentions have been given the initials of the man or men performing the work are entered as an evidence of completion and establishing responsibility. The work required by this sheet is completed and the signature of the night foreman is assurance that the instructions have been followed.

When the machine is driven in from the day's work the driver makes out his report. The vehicle is then placed on the washstand, which will accommodate three, and when washed it is sent to the space assigned to it and charging is begun. Meantime the driver's report has been examined and the daily instructions made out. The work required is performed systematically, and in addition the battery is "watered" and the oil and grease cups filled. Incidentally the vehicles are examined while being worked on by the washers, oilers and battery men, and should there be occasion a report is made to the garage foreman or the night mechanic. The machines are always looked over in a general way if work is being done upon them, and regularly an inspection is made to determine their condition. It will be seen that there is little probability of any defect or condition that might cause damage or failure escaping attention.

If machine work of a character that cannot be performed in the garage is necessary every endeavor is made to make the vehicle serviceable until this can be done. A considerable stock of parts and material is carried and from this practically everything that is needed may be requisitioned. In the event of a battery or motor requiring work that cannot be completed in a night a substitution is made when the vehicle is under contract guaranteed attention, or for the accommodation of a regular customer, so that there need be no delay in service that can possibly be avoided. The company's machines are all worked days, as are the vehicles of other customers, save the American Express Company, which uses one or two nights and some a part of the night, so that the greater part of the work is done between 6 in the evening and 7 in the morning, and Sundays. The busiest day of the week is Sunday, for the inactivity of the wagons affords opportunity for going over them and making examinations and changes of equipment that time might not allow at night or on working days.

A 3.5-ton G. V. truck has been fitted as an emergency machine and this is equipped with a winch,

tools, tackle and whatever experience has taught may be needed, and this is used by the company for its own work as well as for bringing in machines that may have become disabled. This truck is to be equipped with a crane so that labor may be minimized and it will be possible to handle wheels, batteries, motors and other heavy parts should there be occasion to make changes outside of the garage.

The "Daily Charge Report" is made up so that a single sheet may be made to cover the service for six vehicles for a single day, or for one vehicle for six days, and note is made of 24 successive hours from noon, so that the report may be made at any time with reference to voltmeter and ammeter readings, and for a specified vehicle from a stated charging plug. This report shows the condition of the battery at the completion of the charge with relation to gas, temperature and specific gravity, and the wattmeter readings at start and finish. This report is signed by the battery man and submitted to the office. The daily report is sent to the customer and the information is noted in a monthly report compiled for the use of the garage office. When a work outside of the contract requirements is received a "Repair Tag" is made out and on this is noted the size, location and number of the wagon, and the number of the requisition that is made for the part or material used. This tag is attached to the vehicle and the claim check made a part of the tag is detached and given the owner or driver, the check merely serving to identify the wagon through the number of it corresponding with the numerals on the main part of the tag. This tag is used as well for repair work on batteries, etc., and it is utilized as a means of identification between the office and the shop.

In the event of supplies of any character being required by the garage that may be obtained through the company a "Store Order" is made out and submitted to the storekeeper at any specific locality and this becomes a requisition and a voucher for a charge against the garage department. This is a form that is used throughout the accounting system of the company. As filled out a statement is given of the use to be made of the material or supply and the order it is to be used with and the account to which the charge is to be made, where it is to be delivered and the signature of the authority for the order.

The memorandum of a requisition made upon the stock room of the garage gives a serial number, the date, the job number, the name and the address of the person for whom the work is being performed, and besides specifying the quantity itemizes the material. A carbon copy is made that is retained in the stock room, and the original is sent to the office. A "Store Credit" is filled in when material is returned unused or is recovered in a condition to be utilized, and this specifies the material, the quantity and the price, as well as the account to which credit is given. This is another uniform blank of the company.

What is known as a "Store Stock Ledger" is kept in card index form, this being utilized to maintain an

Work Order, Five Inches Length and Eight Inches Width, in Black on White and Pink Sheets, the Former Being the Original and the Latter the Copy, and Differentiated by "Original" and "Duplicate" Above the Serial Number.

The time report also deals with the time of the workmen on repair work of any character, as well as serving as a record for the other departments of the company, this covering the service of the wagons. This gives the name of the department to which the pay roll is to be charged, the rate of pay of the man and wagon, the name of the check number, wagon number, the order number, the location and description of the work, the account, the time of starting and completing the work, the number of hours and the charge for labor and vehicles separately itemized and totalled. The record is attested as correct and is approved, with remarks if the occasion justifies.

inventory as well as a statement of stock received. This gives the catalogue number, the name of the manufacturer, the name, the date, the requisition number, the quantity, the price separately and in stated quantity, the section of the stock room, the bin number and the maximum and the minimum quantity permitted. The entries are of the requisition number, by whom received, the date, the number issued and the balance remaining in stock. The card will permit of 120 entries.

In connection with the work performed for the company a "Work Order" is issued, the order being in duplicate and bearing a serial number. This order is utilized for work performed in the garage as well as by the vehicles or for labor in other departments. This gives the date, the location of the work, its connection if any with other work, and the number of the account to which it is to be charged. This is indorsed with the date of completion, the name of the person performing the work, and is signed by the person having supervision, in the case of the garage this being the manager or the foreman. The original is filed with the record of the job and the copy is sent to the office, this being the data for accounting.

The "Receiving Sheet" that records the receipt of material for the garage is another of the general forms utilized for the garage, and this shows the quantity and the material, the requisition number, the date, from whom received, the name of the receiving clerk, by whom the stock was entered and remarks. This is made in duplicate and the original is kept on file and the copy is sent to the office. Requisitions are made upon the purchasing department on a standard form, these being in duplicate, the copies being retained in the office.

A form of individual battery record is now in preparation, which will show the exact work performed with each battery, the number of charges, the number of discharges, the mileage, the dates of examination and work, the dates of equalization, the condition at differing dates, and the cost of labor and material. This is expected to give exact data of each battery and the cost for each mile of service.

The "Tire Record" is kept in card index form, the tires being classified as to size, the cards showing the number of the wagons on which these sizes are used.

REMARKS

Receiving Clerk ________

Entered by ________

Receiving Sheet, 8.6 Inches Length and Width, in Black on Alternate White and Yellow Sheets, to Be Entered in Duplicate, and Perforated for Loose Leaf Binding.

The data include the make, the date received, the position on the vehicle, the date placed on the wheel, the date removed, the mileage, the number of day's service and remarks.

Monthly reports of the garage are divided to cover vehicles used by the electric department of the company, by the gas department of the company, and by customers of the garage, which is made up to include in parallel columns the number of the vehicle assigned by the company or the customer, the number of the maker of the vehicles for which the garage is agent, the vehicle capacity, the department using the vehicles, the period of service between stated dates, the number of hours in service, the total number of miles, the current as represented by kilowatt-hours, and remarks relative to the machines worthy to note. The footings of the hours of service, miles and kilowatt-hours are given, which represent the entire work, miles traversed and current consumed by the machines stored and maintained at the garage. A glance at the form will show its usefulness. This report is compiled from the daily records and is submitted to the office for the purpose of giving briefly the work accomplished by each vehicle. The possibilities for comparison are especially beneficial.

The occurrence sheet is a report made by a driver of any happening in which he or his vehicle, or both, are involved, which has to do with damage or injury to person or property, and it may be summarized as a letter of record, which is taken as the basis for inquiry or investigation in the event of either being necessary. These sheets are submitted by the garage manager to the manager of the commercial department. They are kept in the file form for reference.

The "Chamber of Horrors" is unique in that it is a large board or tablet on which are permanently displayed such parts of machines as may have been damaged or have failed through neglect, carelessness, incompetency or any other cause within the control of the driver or garage men, and with each is a card describing the cause and how the employees might have prevented the damage and loss of time and expense. It is the belief of the management that this exhibition has a decided value and serves a distinct purpose, as it demonstrates the consequences that may be prevented by the exercise of common sense, and indicates the responsibilities of the man as established by the company.

Another interesting means of educating the drivers is the "paving map" of Baltimore, which is a map showing the streets of the city and indicating which are paved, so that it is possible for the drivers for the company and for customers to select the route that should be best to economize time and minimize wear on the vehicles. This map is carefully revised and kept up to date. It is possible through its use to avoid poor paving and streets on which the surfaces have deteriorated, and to choose the highways where the paving is at the Baltimore standard or the surfaces are good. This has been found especially useful in haulage in sections not familiar to the men.

The insurance record is a standard form used by the company with reference to insuring all its property, and this is an application to the treasurer of the company to secure protection on the garage and its equipment or the vehicles, and when filled it provides the description necessary for the application for the insurance and for incorporation in the policy.

In the garage office are kept the records which are sent to the accounting department of the company, and these are supplied daily or monthly as may be required. The garage itself is known to the auditor

as the subject of "Account No. 300," and in accounting this deals with the operation of the agency for vehicles and the operation of the electric garage. The explanation of the account is as follows:

This account is intended to show the cost of operating the electric garage, 30 South Eutaw street, and the electric vehicles owned and maintained by the company, also to show the income derived from the operation of the garage and vehicles and sale of vehicles and should be sub-divided as follows:

(A) Garage Expense—To be charged with all labor, material, electric current and other expenses of operating and maintaining the electric garage at 30 South Eutaw street, and the charging station at Monument street, storeroom or elsewhere, including the rental of the garage building at 30 South Eutaw street, excluding the maintenance, repairs or depreciation of vehicles.

(B) Vehicle Expense—To be charged with all labor, material and expense for maintenance and repairs of the electric vehicles in connection with work done at the garage at 30 South Eutaw street, including replacement of tires or other parts of vehicles.

Tire Record **Size 3** **Wagon No.**

Make	Date Reset	Pos. on Veh.	Date on Veh.	Date off Veh.	Mileage	No. Days Service	Remarks

Tire Record, Three Inches Length and Five Inches Width, on Card Perforated for Filing.

(C) Vehicle Fixed Charges—To be charged with allowance for interest, depreciation and insurance on electric vehicles owned and operated by the company.

(D) Selling Expense—To be charged with any soliciting or selling expenses in connection with the sale of electric vehicles, including the pay of the drivers for demonstrating purposes and including the per diem charged for any vehicles used for selling or demonstrating purposes.

(E) Garage Income—To be credited with the amount of all charges made to customers, including this company, for care of battery and vehicle storage, washing, oiling and inspection, according to schedule of rates fixed for such service, to be found in the company's selling programme.

(F) Garage Repair Income—To be credited with the amount of all charges made to customers, including this company, for maintenance and repairs of electric vehicles, including replacement of tires and other parts of vehicles to be covered by repair and maintenance charges issued by the garage.

(G) Vehicle Rent—To be credited with the balance remaining in the per diem against departments for the use of electric vehicles after crediting Garage Income and Garage Repair Income, thus balancing sub-accounts (A), (B) and (C).

(H) Income from Sales—Will be credited with any profit made on the sale of electric vehicles.

It is further explained: That it is understood that all electric vehicles owned by the company are to be subject to a per diem charge representing the full cost of the vehicles which will be made up of an allowance for interest, depreciation, insurance, the charge for garage service, storage, washing, oiling and inspection according to the company's schedule for such charges, and the charge for electric current according to the company's schedule of charges. This per diem, together with the cost of maintenance and repairs, as such cost may accrue, is to be charged against the department for such days as the vehicles may be used. The cost of drivers for vehicles is not handled through this account. This is an operating account under the heading of "General Expense, Electric."

In making up the per diem charge it was found that the cost of operating the vehicles did not greatly vary, and after a considerable experience in determining a price that might be applied to each type of vehicle it was decided that it would be best to make a uniform charge of 35 cents an hour for machines up to and including 2000 pounds capacity, and 70 cents an hour for machines of more than 2000 pounds capacity, and these prices are now charged against the departments.

BIG ORDER FOR G. V. MACHINES.

American Express Company Buys 25 Two-Ton Wagons and Three Money Carriers.

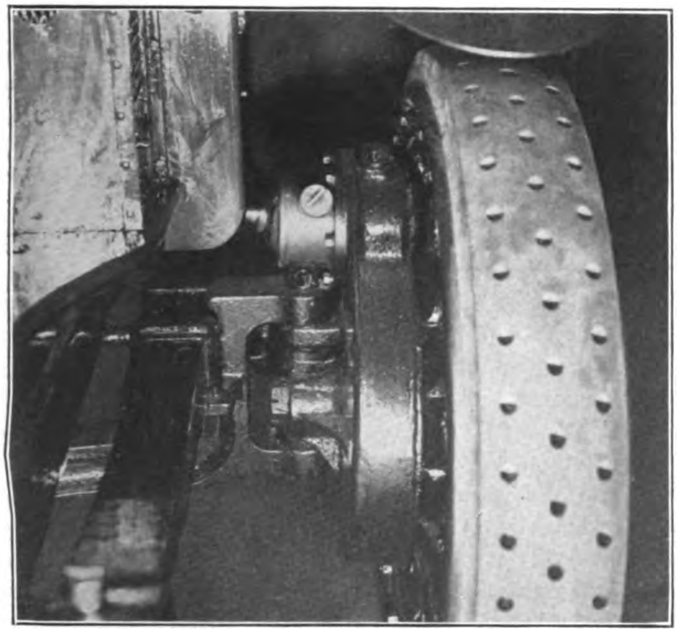
The American Express Company has placed an order for 25 two-ton and three money wagons with the General Vehicle Company, Long Island City, N. Y., and delivery will be begun in March. Of these the 25 machines will be fitted with standard express type covered bodies and they will be the initial installation at Boston, Mass., while the others will be used in New York. The company has electric machines in service elsewhere in the country, but the translation of the Boston delivery equipment was not determined until after exhaustive observation of differing forms of conveyance and accurate data had been compiled, all with reference to climatic, traffic and other conditions, and to establish what would be the most dependable and economical form of distribution and haulage in that city.

In this determination the company had the benefit of its excellent system of accounting of horse delivery expense and the scientific observing of two makes of electric and three makes of gasoline vehicles. The recommendation for the Boston service was from the showing for adaptability, reliability and economy. It is expected that the machines will be delivered at the rate of 10 a week, and that with the change the service will be improved.

WALTER TO BUILD UNDER LATIL PATENTS.

Front Wheel Driven Machines, Used for Nine Years in France, to Be Manufactured in New York---Details of Design and Construction.

SIMULTANEOUS with the exhibition of the Walter-Latil service wagons at Madison Square Garden was the announcement that the Walter Motor Truck Company, New York City, had acquired the



The Front Wheel Drive of the Walter-Latil Truck, a Construction for Which the American Manufacturing Rights Have Been Secured by the Walter Motor Truck Company.

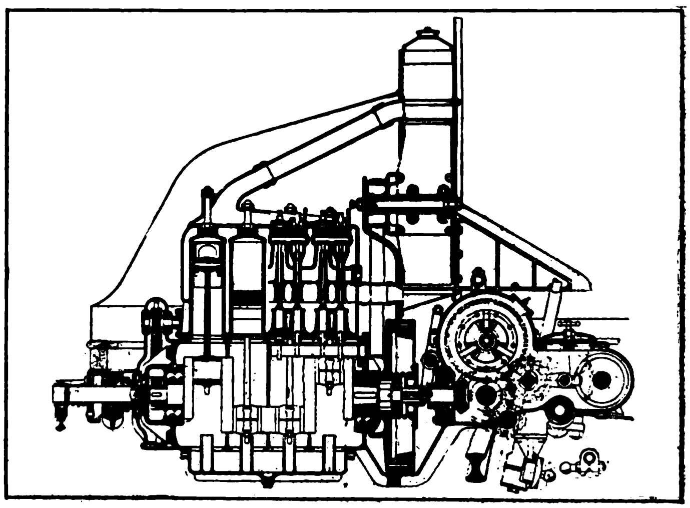
American right to manufacture under the patents issued by France to Latil Freres, and that it was purposed to build there vehicles in sizes from one to five tons. The Latil is a front wheel driven automobile in which the power is transmitted from the engine through a bevel gear to a cross or counter-shaft carrying spur pinions at the outer ends, which engage with spur gears fixed to the front wheels. The first Latil was produced nine years ago and it has been long recognized as one of the standard machines of Europe, and following the investigation by the engineers of the Walter company and the acquisition of the American right, similar rights were acquired by other concerns, these including England and several other European nations.

The Latil construction is primarily a chassis carried on two wheels, which may be coupled to any form of rear equipment, and from which it may be conveniently detached, or it may include an entire vehicle. That shown at New York was a service wagon with the chassis mounted on four wheels. The front or traction wheels are shod with rubber tires, but the rear wheels may have either rubber or steel shoes. As utilized in Europe the steel rear tires are generally the equipment, but rubber is used when the machines carry passengers or fragile freight. The two-wheel chassis has been found very practical for changing the body equipment, and in some instances the attachment is so made that the chassis coupling will permit dropping the rear end of the body and raising the forward end and supporting it rigidly inclined for loading or unloading. It is entirely practical to convert horse equipment for use with the chassis.

The claims are made that with about 80 per cent. of the load taken on the rear wheels, and with practically a constant load carried on the front wheels, the machine has unusually easy riding qualities; that the front wheel drive minimizes skidding; that brakes may be used on both front and rear wheels independently or in combination on all four wheels; that with the chassis construction the entire mechanism is accessible at all times, no matter whether or not the vehicle is loaded and that driving is easy through the rotary movement of the front wheels. It is also maintained that a smaller engine will afford a satisfactory speed and hill climbing capacity. Two types of chassis are built in France, the one for vehicles with capacity ranging from one to three tons and the other for capacities of four and five tons. With either the power transmission is identical, but the other details of construction differ.

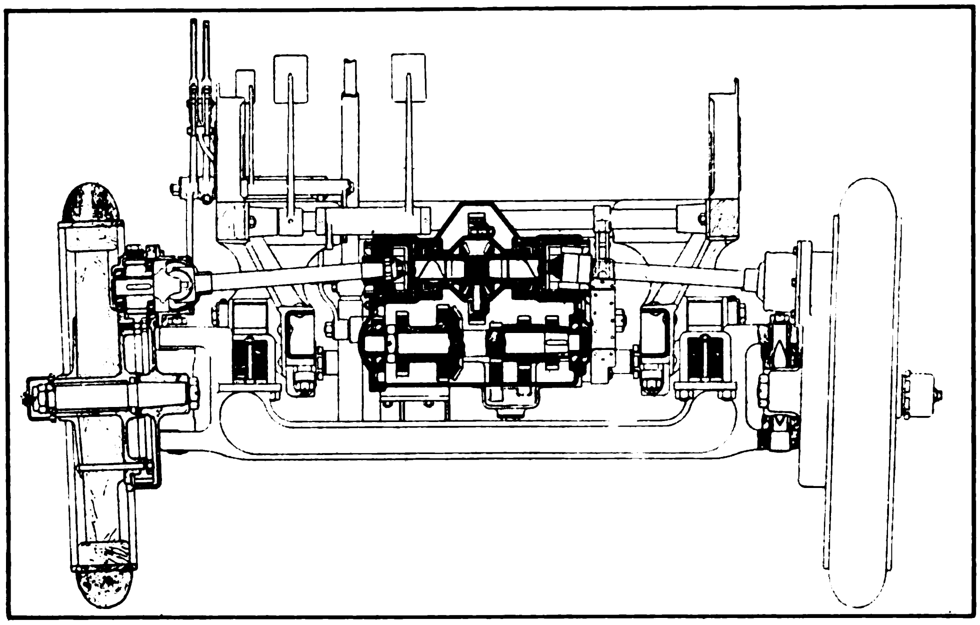
The smaller vehicles are equipped with a four-cylinder engine, rated at 18 horsepower. The cylinders are cast en bloc with bore of 85 mm and stroke of 140 mm, corresponding to 3.35 and 5.5 inches, respectively. The valves are all arranged on one side and the camshaft is chain driven and is provided with a jockey pulley adjustment.

Lubrication is by a combination of the pump and splash systems, the pump taking oil from a sump in



Longitudinal Section of the Power Transmission System of the Walter-Latil Small Type of Chassis.

the crankcase to a reservoir on the dash, whence it is forced through separate leads to troughs cast in the lower portion of the crankcase into which the big ends dip. Ignition is by Bosch high-tension magneto. Cool-



Transverse Section of the Power Transmission System of the Walter-Latil Small Type of Chassis.

ing is by thermo-syphon, the radiator being mounted in front of the dash. In addition a fan is carried on a shaft fitted with ball bearings and driven by means of a belt from a pulley cast on the front of the flywheel.

In order to make the engine as compact as possible, the crankshaft has no centre bearing, but double ball bearings of ample size are housed at each end of the crankcase and carry the crankshaft. The camshaft also runs on ball bearings.

The change speed gearing and differential are enclosed in one case bolted to the rear of the crankcase, the use of a long clutch shaft and universal joints being eliminated. In this case the leather faced cone clutch slides on a short shaft, which drives the main gearshaft by means of bevel gearing. The main shaft and the layshaft run at right angles to the motor.

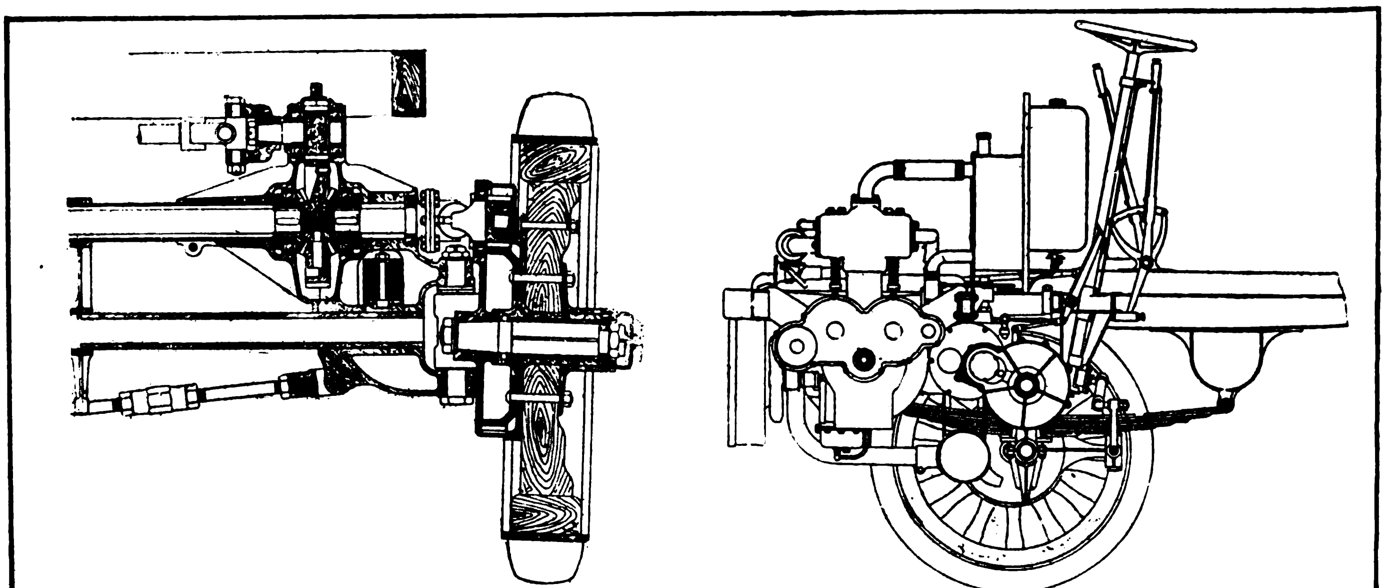
Four forward speeds and reverse are provided, the high speed being direct to the differential. The speed changes are effected by means of a lever operating in a "tramway," and the drive to the differential is by spur gearing. Both gearshafts run on ball bearings and felt oil retainers are provided wherever necessary.

The drive from the differential to the road wheels is taken through two cardan shafts, each fitted with two universal joints. The joints at the ends of the shafts nearest the wheels are of the ball and socket type, and are enclosed in grease cases. The angle of these two shafts is not great, a feature which is held to make for little loss of power in friction at the joints.

In order to allow for variations in the angle of the cardan shafts, the joints nearest the differential gear are made so as to permit considerable end travel. As a precaution against the forks coming out of mesh with the ball joints, springs are inserted between the ends of the shafts and the universal joint boxes.

The ball bearings of the pinions which drive the gears attached to the two front wheels are housed in castings, which also carry stub axles and the arms to which the steering rods are atached. These castings, which serve in some measure as dust covers to the pinions and gears, swivel between the jaws of the main portion of the front axle.

The engine and gears are suspended from three points. Two arms extending downward from the two main longitudinal members are secured to the gearbox, and a bracket attached to the front cross member and terminating in a socket, into which fits a ball



Constructional Detail of the Walter-Latil Large Type of Chassis: At Left, Transverse Section Showing the Differential and the Driving Gearing; at Right, a Longitudinal View of the Power Plant Assembly.

secured to the front of the crankcase, carries the motor.

The steering gear is of the usual worm and segment type. The foot brake acts upon a drum carried on an extension of the speed gearshaft and takes effect upon the front wheels. A side lever operates two band brakes on the rear wheels. In the event of steel tires being utilized on the latter the brakes are arranged to act upon the rims.

The larger type of chassis is fitted with motors of 27 or 30 horsepower. The four cylinders are cast in pairs, and have bore of 105 or 110 mm and stroke of 140. The valves are arranged on both sides of the motor and are interchangeable. Their lift may be regulated by adjustable tappets. Both camshafts are chain drive and are provided with the same form of adjustment as that of the smaller machine.

Ignition and lubrication are the same, but the cooling system is different. Circulation is maintained by a gear driven pump, the discharge from the cylinders passing into a tank on the front of the dash, whence it finds its way to the tubular radiator suspended at the front of the chassis frame, and so back into the cylinders. The fan is carried on a bracket secured to the side of the crankcase, and is belt driven from a pulley rotated by one of the camshafts.

The leather faced cone clutch is carried in the flywheel in the usual manner, and on the clutch shaft is a spur gear which is in constant mesh with a pinion on the gearshaft in the gearbox, the last named being at the rear of the motor. The differential gears are in a separate case, bolted to a casting secured to the front axle. Drive to the differential is transmitted by a small shaft and universal joint to a spur wheel in constant mesh with the crown wheel of the differential.

Owing to the arrangement of the mechanism, the whole of the transmission gearing is located at one side of the chassis frame, necessitating the use of cardan shafts of unequal length. However, these shafts work in a horizontal position instead of at an angle, rendering the use of ball and socket grease casings over the universal joints unnecessary, and no universal joints are required at the differential ends.

Additional details are presented in accompanying sketches, those brought out herein being the leading features. The chassis frames in the lighter vehicles are of pressed steel, while in the larger rolled channel steel strengthened with wood is used. The speeds vary from 12 to 18 miles an hour, according to the carrying capacity.

Included among the orders recently received by the Atlantic Vehicle Company, New York, N. Y., and Newark, N. J., maker of Atlantic electric wagons and trucks, were those for six five-ton trucks for the Ebling Brewing Company, one five-ton truck for the Wall Rope Works, two five-ton trucks for the Kips Bay Brewing & Malting Company, and a one-ton wagon for A. Silz, Inc., all located in New York. These machines are now under construction.

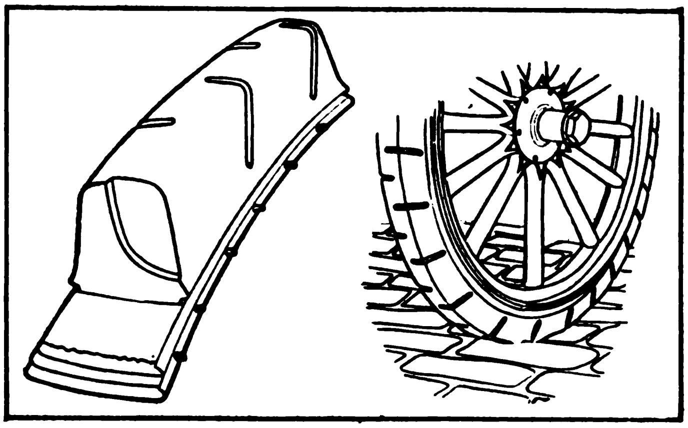
SWINEHART HEADS NEW COMPANY.

Will Direct Manufacture of Tires by New Processes for All Forms of Vehicles.

The St. Louis Tire & Rubber Co., University City, St. Louis, Mo., has been organized with J. A. Swinehart as vice president and manager, and has begun the manufacture of solid and pneumatic tires. Mr. Swinehart retired from the industry three years ago, but was so much impressed with the service given by the St. Louis tire in experiments covering more than two years that he has again entered business.

The accompanying illustration shows a section of the solid type, which is alternately notched at either side at an angle of 20 degrees to the radii, a construction that is claimed will prevent skidding and obviate the use of chains on wet or muddy paving. Cross wires slanting forward and backward are placed in the base to prevent creeping of the tire when the wheel is driven in either direction. It will fit any clincher rim, whether detachable or single section.

It is claimed for this tire that it is very resilient,



Sketches Showing the New Notched St. Louis Solid Tire That Is Claimed Will Not Skid.

will require less current than a solid shoe when used on electric vehicles, that the notches give certain traction and clean a path for the tire where the road is wet or muddy. It is held that a rough surface on a smooth paving will not make as good a contact as a perfectly smooth surface on a clean pavement.

The company manufactures as well a truck tire of the flange type, and a pneumatic shoe made under a new principle. The carcass is expanded within the mold by hydraulic pressure, which insures against buckling and pinching of the fabric, and equally distributes the strain on all the layers of fabric.

The Electric Storage Battery Company of Philadelphia has issued invitations to a dinner to be tendered to the electric vehicle manufacturers and the distributors of Exide batteries at the Mid Day Club, 68 West Munroe street, Chicago, Ill., the evening of Feb. 5 at 7. This will be one of the features of the entertainment during the pleasure car show in the Windy City, and it will be especially attractive because of the unusually excellent speakers who will attend.

PEERLESS PLANS FOR EXPANSION.

Increase of Capital and Acquisition of New Stockholders Make for Advancement of Truck Line.

Successful in producing and marketing Peerless pleasure cars and trucks under a moderate capitalization, the Peerless Motor Car Company, Cleveland, O., is planning to do business on a larger scale during 1913. Its authorized capital has been increased from $3,000,000 to $10,000,000 and several new stockholders of wealth and influence have entered the company. While the pleasure car will in no wise be neglected, it is understood that much more energy and capital than heretofore will be applied to the advancement of the commercial vehicle line.

The Peerless company has decided to pay a dividend of 40 per cent. to its shareholders, payable from the surplus of the common stock. The stockholders also have been offered the right to exchange one-half of their holdings for an equal amount of preferred stock. A majority has announced its intention to make the exchange. The increase in capital is designed to carry out the development plans of the officers who have subscribed so liberally to the new stock and of the new interests working in complete harmony.

The new stockholders have been successful in kindred fields and the Peerless company will gain much in 1913 by their determination to take personal interest as members of the board of directors. These men are: E. S. Terry, H. A. Tremaine, B. G. Tremaine, J. B. Crouse and J. Robert Crouse. The new year was started by the Peerless company with a paid-in capital of $4,300.000 and assets, after deducting all liabilities of every kind, of between $5,000,000 and $6,000,000, exclusive of patents, trade marks and good will.

TO BECOME CONSULTING EXPERT.

C. T. Myers Leaves General Motors Truck Company to Engage in New Line of Endeavor.

Cornelius T. Myers, who for the past two years has been mechanical engineer and chief engineer of the General Motors Truck Company, Detroit, maker of G. M. C. trucks, has severed his connection with the company. He is returning to the consulting work which he dropped to assist President Neal in caring for some of the engineering problems then confronting the General Motors Truck Company.

When Mr. Myers completes some special work which he has on hand he will be in a position to carry on a consulting engineering practise in all lines of automobile activity, but particularly in the commercial vehicle field. Among other things he will make a specialty of reports to prospective purchasers on their local conditions with respect to motor transportation, and on the particulars of the various machines on the market. His office is at present located at 49 Pingree street, Detroit.

TAKES OVER INVADER OIL.

New Concern Organized to Produce Lubricant Made Prominent by Chas. F. Kellom & Co.

The firm of Chas. F. Kellom & Co., Philadelphia, Penn., maker of Invader oil, has been acquired by a new corporation to be known as the Invader Oil Company. T. E. Tomlinson, a pioneer in the study of special oils for automobile use, will be vice president and general manager of the new concern. Charles F. Kellom will remain as president and the Kellom manufacturing and selling organization will remain intact. H. Dunthorn will be secretary and treasurer of the company, which has been incorporated under the laws of New Jersey with an authorized capital of $250,000. The factory will remain at 113 Arch street, Philadelphia, and the general offices will be located at 80 Broad street, New York City.

The sales staff of the Kellom company, which includes D. A. Scheu, who for many years covered the New England territory, will be retained, and in addition Mr. Tomlinson will have associated with him a number of the better known men who were identified with him in previous ventures. Among them are: H. Dunthorn, J. T. Rose, A. A. Francesconi, Howard Plowman, Harvey Wilkins, E. Kalkhof, F. Menke and A. Rafelson. Mr. Kellom began the oil business in 1881 and claims to be the first to introduce light oil for use in automobiles. Mr. Tomlinson first engaged in the business several years ago and created the famous Havoline oil, which attained national prominence. He later organized the Wolverine company, which he built to large proportions.

RESIGNS FROM REO COMPANY.

Charles E. Easton Joins Advertising Agency Headed by Gleeson Murphy, a Former G. M. C. Man.

Charles E. Easton, formerly sales manager of the Reo Motor Truck Company, Lansing, Mich., has resigned his position to join the Detroit staff of the H. K. McCann Company, an advertising agency, of which Gleeson Murphy, formerly with the General Motors Company, is the head. Mr. Easton has acted as advertising director of the Reo concern for the past two years and joins the McCann company well equipped for his new work.

Before joining the Reo company Mr. Easton had charge of the advertising departments of the Buffalo Forge Company and the E. R. Thomas Automobile Company, both of Buffalo, N. Y. He also handled the advertising department of the Inter-State Automobile Company, Muncie, Ind. He is a graduate engineer who has made a study of advertising along several different lines of business. He has planned and handled both mechanical and sales management in his various connections in the automobile and accessory industries during the past eight years.

ELECTRIC-GASOLINE SERVICE STATION.

Combination Garage of the Empire State General Vehicle Company, Rochester, N. Y., That Sells and Garages Pleasure and Industrial Machines and Has Facilities for Care and Maintenance Distinctly Promotive of Their Use.

By William W. Scott.

THE service afforded by the public station of the Empire State General Vehicle Company, 15 Circle street, Rochester, N. Y., is an example of the possibilities of the combination garage that is probably unequalled in America, and the policy of the company has established it as one of the most progressive in the country. This statement is made with a knowledge of some admirable installations, but not one of these has worked out service to meet the requirements of so many differing systems of delivery. To illustrate, this company is the agent for electric and gasoline service wagons and pleasure vehicles as well as industrial trucks for manufacturing plants, and it has the usual gasoline machine garage where every attention is possible, but in addition it will undertake the garaging and maintenance of electric service wagons at stated prices a day, and it has perfected a system that will be inaugurated March 1 in all probability, so that it will rent batteries on a mileage basis, and the customer can have what may be regarded as a constant battery service when in need of more than the usual capacity of his equipment.

Combination Electric and Gasoline Garage of the Empire State General Vehicle Company, 15 Circle Street, Rochester, N. Y.

This mileage rental of batteries will be similar to the system inaugurated by the Hartford Electric Light Company, Hartford, Conn., but there is only one other concern in the country that has undertaken the maintenance contract of electric machines, and this with a single firm's equipment, so it can be stated that the Empire State company is the pioneer in this form of service. The garage now used is located about a mile and a half from the centre of the city, which has been an unfavorable condition so far as encouraging patronage is concerned, and it is not improbable that within a comparatively short time a new location will be obtained which will be much more convenient to the business district.

The Rochester Railway & Light Company was one of the first concerns in Rochester to use electric vehicles and it established a garage in which to store and maintain its machines. There had been several agents for electric service wagons in Rochester, and a number of purchasers had failed to realize the results expected, largely through the lack of facilities for upkeep and ignorance of the attention that should have been systematically given.

The Empire State General Vehicle Company was organized after a very careful investigation of the possibilities of highway haulage by mechanical vehicle, and the conclusion had been reached that to develop the enterprise to a large measure of productiveness it was necessary to have equipment and facilities to meet every requirement of the people. By this is meant that it was not only necessary to have the agency of several standard makes of vehicles and the garage for storing them, but it was desirable to efficiently maintain them and to afford options of form of maintenance to insure to the owners a constant and unfailing service.

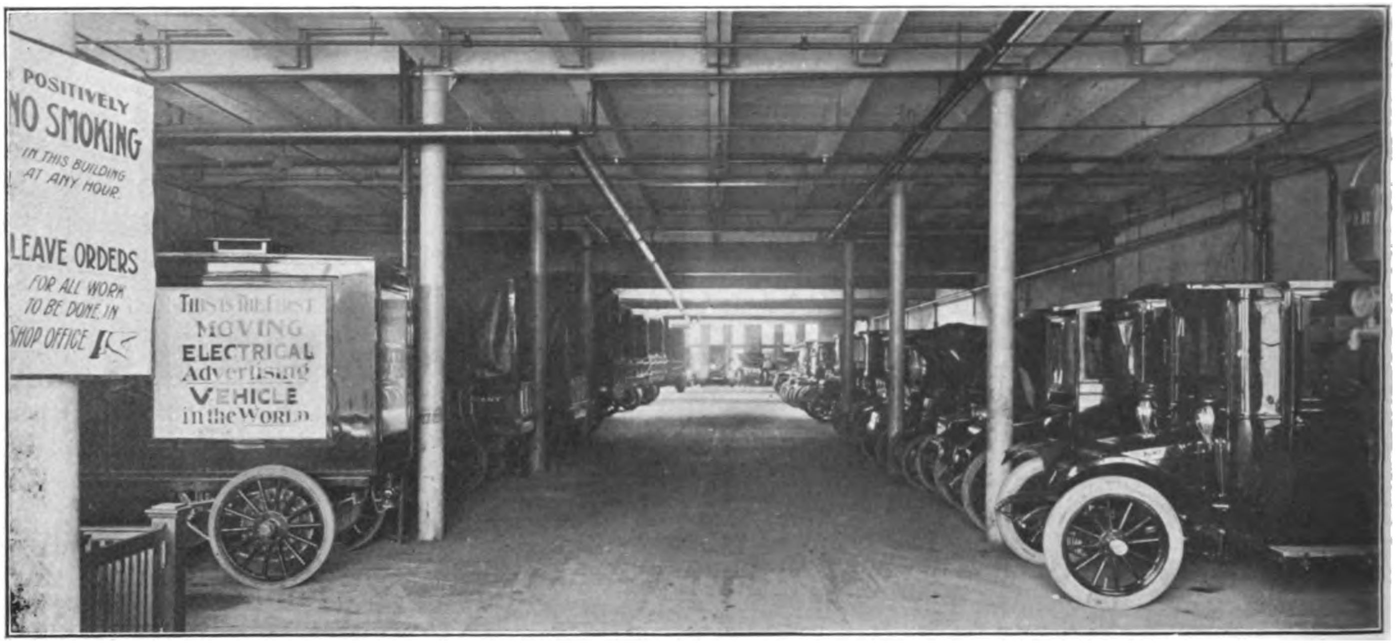
As a business proposition it was believed that it would be best to deal with both electric and gasoline machines, and to be able to supply any demand for transportation that might eventuate. When the company was formed the first agency secured was that of the General Vehicle electric wagons, and to provide garaging facilities that would be sufficient and assure customers of a satisfactory attention a contract was

made for the temporary use of the garage of the Railway & Light Company. By this contract the company fortified itself against the difficulties that might be met with in the establishment of an electric service station and insured the co-operation, at least, of the central station in development work.

The attitude of the central station with reference to the owners of electric vehicles is decidedly important, but so far as the company was concerned the policy established was to make possible the greatest economy in the use of all service machines, and to insure this economy to the owner. After the organization had been perfected the company decided to locate its salesrooms and garage at Circle street, in the first building erected on the present site. This was a structure 210 by 50 feet, with a two-story section across the front end, with the remainder a high single story with a saw-tooth roof to afford sufficient light. This building was of brick with stone trimming and was de-

As the garage is now utilized the old or right section as seen from the front is given over to gasoline machines and the repair shop, and the new or left section is the electric garage and charging station. The two divisions are separated by a heavy wall extending the full length, with a large door at the rear through which access is had from the electric garage to the repair shop, and by a door near the front of the building. At the right of the entrance to the electric side is a portion of the office, and at the left a salesroom. The other section houses a part of the office, a waiting room, a stock room, etc. Either side back of the head houses is not obstructed, the roofs being supported by trusses, so that every inch of room may be utilized.

Besides the General Vehicle electric wagons the company secured the agencies for the G. M. C. gasoline wagons, and the Buffalo Electric Vehicle Company's and the Locomobile Company of America's lines of pleasure cars. In addition the Automatic



Interior of the Electric Section of the Garage of the Empire State General Vehicle Company, Showing the Storage Space Available on the Main Floor.

signed with an office and salesrooms in the front, with an entrance between the two into the garage that occupied the greater part of the structure. The equipment included charging panels and the usual electrical installation necessary, machine tools, etc.

The removal to the garage was made in October, 1911, and the following spring the garage was increased by the erection of a second building the same size as the other, but somewhat differently designed. The front is two stories and is full height instead of gabled, and this affords a salesroom on the second floor and facilities for painting and finishing. The roof is lighted by skylights and the rear of each building is well lighted from large mill windows at the rear. The garage now covers about 21,000 square feet of ground, of which about 15,000 is given over to storage space, the remainder being occupied by the office, the salesroom, the repair shop, battery room, elevator and washstands.

Transportation Company's industrial trucks, these being propelled by electric power, were taken on. With this line the organization was developed and extended, there being four distinct divisions of the sales department, which is primarily divided into pleasure vehicle and service or truck sales sections, and each of these is directed by a manager. The salesmen are assigned to the division in which they are best adapted to serve. The garage and repair and maintenance departments are similarly organized and the whole are under the supervision of a general manager, who is vice president of the company.

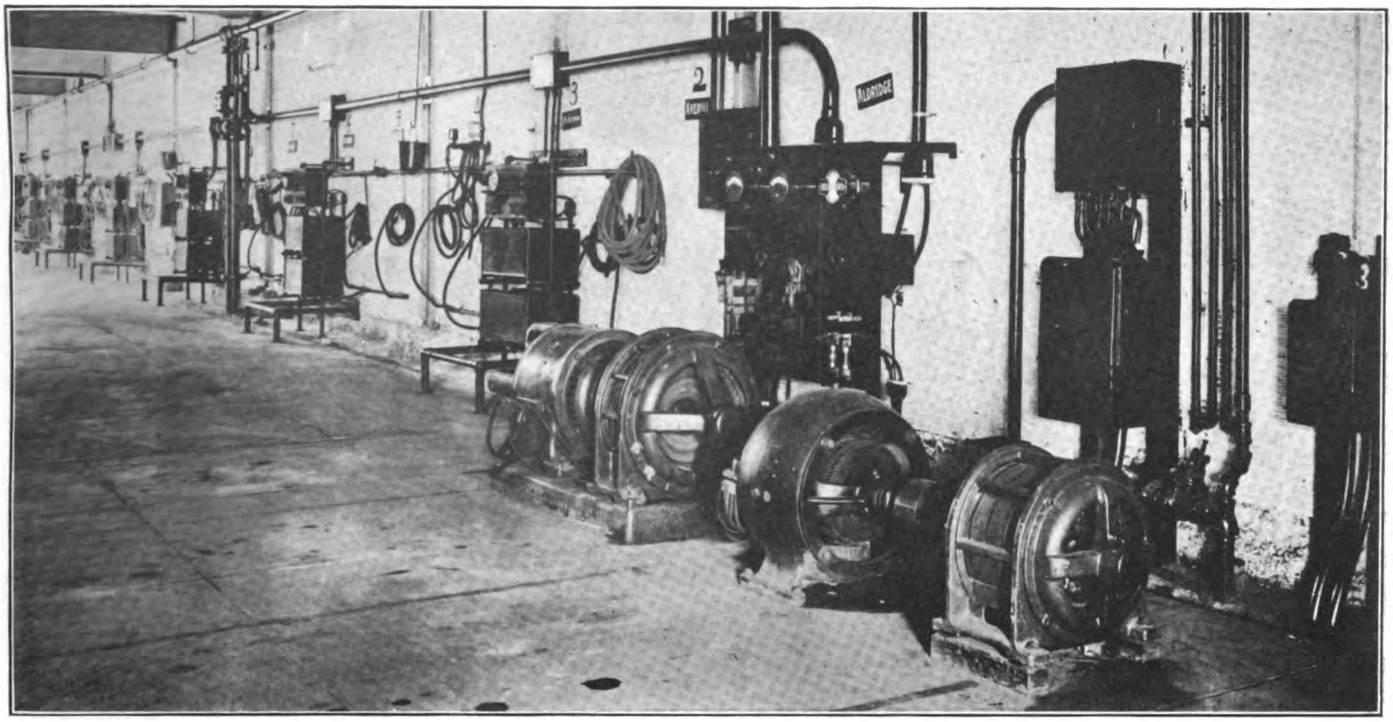
The selling plan is to be able to supply a well known and entirely practical vehicle for whatever service may be required, and to make recommendation of what form of power will, in the judgment of the sales manager, give the best results, or to supply the vehicles which will meet the requirements of the person desiring them. This policy is believed to be what

will reach the largest number of probable buyers, and while it is not practical to have representation of more than one line of machines, the agencies were made with the purpose of selling service wagons of as wide a range of sizes as could be obtained, so that nearly every character of delivery equipment could be supplied. With the different sizes of the electric and gasoline wagons the light and fast vehicles or the heavy and slower machines can be delivered, and with the resources of the companies deliveries can be made within a comparatively short time.

Having established the policy and the organization for the sale of machines it was found that the demands for garaging and maintenance were imperative. The man or firm having an initial installation of one or two gasoline wagons may feel that it is wise to have his own garage, but there are others who believe that it is best to have the service regular and vious that competent men cannot be employed at the same ratio of expense with the smaller number. Yet their services are just as essential.

The establishment of the garage and the sales agencies was with a view of developing a successful business, which might eventually assume large proportions, and it was realized that reputation for service was absolutely necessary. To afford this to the business men of Rochester and vicinity has been the purpose of the company, and while time must necessarily elapse for the concern to receive the recognition that is hoped for, there is no doubt of the soundness of the policy or the character of the results.

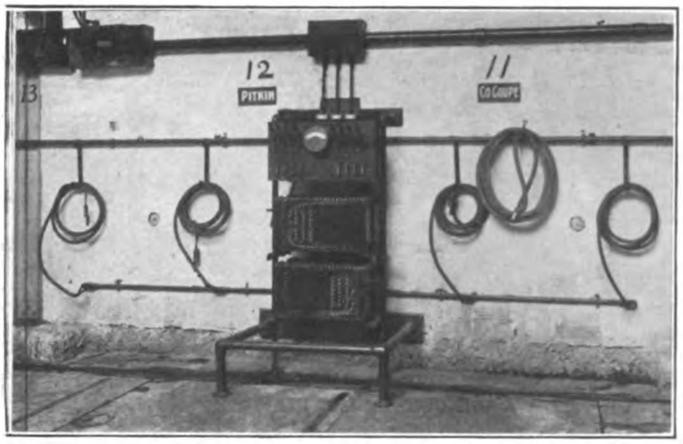
The progressiveness of the company is evidenced by its adoption of several systems of attention which have not been carefully worked out from long experience. With reference to electric vehicles the one is the maintenance of a machine of a given capacity for



Motor Generator Set and Charging Panels Serving Four Machines Each in the Electric Section of the Empire State General Vehicle Company's Garage.

systematic, as afforded by a public station, rather than take the chance of the more uncertain attention that will be given by a driver or drivers, with such assistance as may be employed from time to time. While there are some purchasers of wagons and trucks who are seemingly satisfied with their own knowledge and resources there are others who realize that the real economy of the motor vehicle is in keeping it serviceable at all times, or as near to this condition as is possible. It is this class that demands the high class garage and the best of attention. With electric machines it was found that there was an even more insistent demand for garaging under the supervision of experts, and this can be said to obtain until an installation of considerable proportions has been made, because it will require no more men to properly attend and maintain 40 vehicles than it will 10, and it is ob-

a stated amount daily and another is the battery rental on a mileage basis, while a third is the adoption of the gravity charging method for batteries, and these are regarded as being distinct progression as compared with the policies and service of other stations. While the company has not reached a point where it has been unable to provide for all who might desire service, it is prepared to give preference to the machines for which it is agent should there be occasion to refuse garaging because of lack of space for storage, and in undertaking repair and restoration work, for it is maintained that while the company will give all the attention possible for those who desire work done it is obligated to consider those who own the makes of machines it sells, and those who purchased through the company, before others who have no reason to claim consideration. Not only this, the company will event-



Charging Panel and the Leads in the Garage of the Empire State General Vehicle Company, Where the Gravity System Is Used.

ually devote its endeavors principally and perhaps wholly to service vehicles, and will give over pleasure machines when this can be done consistently. Having divided its garage into divisions for electric and gasoline wagons and cars, it is intended that the one shall not in any way encroach upon the other, and with the growth of the business there shall be the same character of attention given to either, no matter what the number.

In the conduct of the garage it will be understood that the two departments are separate and distinct, and the service given in either is upon an entirely different basis. In this article the electric department will be considered at length because it differs materially from other electric garages, and the gasoline department is conducted along lines which are generally the vogue with public service stations. The matter of pleasure vehicles will be but briefly referred to.

The basis of the service is shown by the price schedule which accompanies this discussion.

It will be noted that the schedule of prices for the gasoline pleasure cars provide for the service that is generally given in garages, and besides washing and polishing such assistance as might be desired occasionally, such as a carburetor adjustment, tightening a bolt, changing a tire or help that can be given consistently. Work that would require time, or time and material, is charged for in addition. The garage has a full stock of supplies and accessories that are sold at standard prices and with the guarantees given by the manufacturers.

The prices for gasoline trucks and wagons are for storage only, and as the drivers of these machines are expected to look after their outfits, even to washing, the garage employees are not called upon to assist them. If work of any kind is done or material or supplies furnished, additional charge is made. For the machines for which the company is agent a stock of parts is kept and these are available as desired, but if a replacement is necessary the driver does it or, if the work is performed by the garage men, a charge for the time and part is made. Of course fuel and lubricants are furnished and charged to the owner as delivered.

Gasoline Pleasure Cars.

Limousine, a month	$35
Large touring car, a month	35
Small touring car, a month	20
Runabouts, a month	20

Prices include washing, polishing and minor adjustments.

Electric Pleasure Cars.

Coupes and victorias, a month	$35

Price includes charging, washing, polishing, delivery and minor adjustments.

Gasoline Trucks and Wagons.

Three tons, a month	$20
2.5 tons, a month	20
One ton, a month	20
1000 pounds, a month	15

No washing or polishing or minor adjustments, merely storage space, included in these prices.

Electric Trucks and Wagons.

Five tons, a month	$60
3.5 tons, a month	55
Two tons, a month	50
One ton, a month	40
1000 pounds, a month	35
700 pounds, a month	35

Prices include washing, polishing, charging and minor adjustments.

With reference to the gasoline vehicle department of the garage and the handling of the fuel, lubricants, supplies and accessories, conventional methods are the vogue and system is observed that there may be no loss by waste or neglect to make record of deliveries, or from the drivers helping themselves to what might be left uncared or not accounted for.

From	To	From	To	Remarks

Card Record Filled When a Contract for Service Is Made for the Electric Section and Continued During Period Machine Is Garaged; Card Five Inches Length and Eight Inches Width, Printed in Black on White—Reverse of Card Below.

The electric department, however, gives an entirely different character of attention, and it will be seen that this differs from any other in that the machine may be garaged under any one of four services. The pleasure vehicles are provided for at a stated price, as may be the wagons and trucks, or the second classification may be on a maintenance service, or a storage and battery mileage plan, while the owner can, if he desires, garage his own machine and use rented batteries.

In this department the records are as simple as possible and as the battery service was but recently inaugurated the forms that are at present utilized may be changed or amplified as may seem best with greater experience. The accounting is not to be analyzed, but the records used in connection with the work and from which the charges for service are established will be dealt with in the sequence of their use.

When a vehicle is received at the garage form No. 1 is filled, and this, it will be noted, indicates the number of the space to be occupied, the date, the name and address of the owner, the make of the vehicle, the type, state license or registration number, the make of the battery, type of battery, number of cells, number of trays, the rate to be charged monthly, and a statement of the general condition of the machine when received. This information is entered on a card that is kept in a file. This card has a portion of the obverse for "remarks" with relation to the condition or the service, and the reverse is intended to show the periods of storage and whatever facts may be desirable to record. The card shows from whom orders for work and material shall be received, who shall drive it, and from whom the authority with relation to attention outside of that provided for by the monthly charge may come, either the owner or his driver, or work may be left to the discretion of the garage foreman when the report has been made to that official.

The pleasure cars are delivered wherever ordered by "chasers," and where the distance justifies car fare is provided for the return of the young men doing this work. When cars are sent for to be returned to the garage car fare is allowed. This is an expense that must be accounted for. To have accurate knowledge of the use of the pleasure machines what is known as a "Daily Garage Sheet" is kept, and this shows the name and address of each owner, the time a call is received, the time the machine is sent out, the name of the "chaser" in charge of it, the time he returns and whether or not car fare is given; when the call is received for the return of the machine, the time the "chaser" leaves the garage, the time he returns, whether car fare is given, the condition of the car and where it was called. If the car is washed and charged these facts are also noted, so that a very good knowledge of the service of the vehicle may be had and the authority for its use can be established. This record is filed and it will give useful information with relation to the use of each machine.

With the electric wagon or truck taken for service the same form of card is filled, and this is placed in a separate file. The time the machine is required for use each day and the addresses of the driver and owner are noted. The authority for work is established and it is understood that so far as is practicable the machine will be ready for use as desired. That is, when a

DAILY GARAGE SHEET Date

NAME	ADDRESS	TIME CALLED	OUT			CAR FARE	TIME CALLED	IN			CAR FARE	CONDITION OF CAR	WORK		WHERE CALLED

"Daily Garage Sheet" Used in Recording the Service of the Electric Pleasure Cars, 8.5 Inches Length and 14 Inches Width, Printed with Black on White with Red Longitudinal and Blue Transverse Rules, Arranged for 15 Entries.

Date
Employee's No.
RATE

Job No.	No. Hrs.	Work Done

"Time Card" Six Inches Length and 4.25 Inches Width, Printed in Black on Yellow Card with Rules for 12 Entries.

work is undertaken it will be completed so that the wagon will be in an operative condition if this is possible.

Next in the office what is known as a "job" is made out and this is a form of record on which will be entered all the work not included in the monthly service charge and material or parts that may be needed. This "job" is given a number and this "number" is posted on a board in the repair shop together with the name of the owner and the identity of the machine. When work of any character is performed it is credited to the "job" number, and this record goes to the office, and from this the charge is made.

The posting of the number makes it easy for the mechanics to keep their time wherever it is given, and as the time is thus credited to each job or number the work done may always be accounted for and the cost of labor established. From this "job" record in the office the monthly bill is made out and the entries, plus the monthly price paid, show the amount payable.

All of the time of the mechanics is accounted for on a card that is issued for each man for each day, and this shows the date, the name and the rate of wages paid. On the card is entered the number of the "job," the number of hours and the work done with reference to each assignment by the foreman, and this card accounts for the entire time during which the man is employed.

The "job," as it is known, is actually a shop order, which is made out in duplicate, having a serial number that is assigned for a month to a single vehicle for convenience of record, and this applies to every machine in the electric section. The order is filled with the date, registration number of the customer, the name, the terms and the date the work is to be completed when work is performed for those in the gasoline section or for casual or transient customers. As the orders for work are issued daily, the necessity of posting those numbers that are to be continued through the month is obvious, for these numbers do not necessarily continue serially, although the orders are so numbered. To simplify the office and repair shop record the electric and gasoline sections of the garage are not separated with reference to the repairing, although in the accounting the business is divided that there may be accurate knowledge of either division.

The copies of these orders are issued to the repair shop, and if the numbers are assigned for a month then whatever should be charged to them during that period in the way of material or time are entered on the copies by the foremen when a requisition is made or work is done, together with the price a unit and the total amount. The original order is retained in the office and on this on the obverse is made the same entries as are shown by the copy in the repair shop, but on the reverse is shown the "cost of job," which gives the dates, names of employees, number of hours, cost an hour, sales rate, cost and selling price, with reference to labor, and the requisition numbers, quantity, description, cost price and selling price with reference to material, together with the total costs of labor and

material, the selling price of the aggregate and the profit. From this "cost of job" the bill is made out and every detail can be supplied by the requisitions and time cards. The orders are kept in loose leaf binders and are a record of all work done in the repair shop.

As may be assumed the orders refer to work other than actual labor on the mechanism of the wagons or cars and include every form of attention to the batteries, aside from that required by the provisions of the contract for service. For repairing or restoration it is necessary to have material or parts, and these cannot be delivered from the stockroom without a requisition, and this must show the number of the job, the date, the name and address of the person for whom the work is being done, and the quantity of material required, and when this is delivered the number of the bin and the price a unit and the total amount is entered. The delivery is receipted for.

The electric machine on a service basis is taken out for the day, for instance, by the driver. On the return at night the driver makes report to the foreman of any condition of operation that indicates the need of adjustment or restoration or attention, and this refers to the battery as well as the mechanism. The foreman examines the machine and then gives instructions for whatever work and the use of such material as may be necessary to make repair, but in the absence of his authority, when such is required from the owner, this is obtained. So far as possible all work is planned so there will be the least retardation of a customer's service, and if it is imperative notification is given the owner so that he may arrange for a temporary substitute for his machine.

If the work is outside of the requirements of the service then a "job" is made out as has been outlined, but if not the care is given in the regular work. If the machine does not require attention by the foreman, it is washed, driven to its regular space and placed on charge. If work is necessary that may be dirty, this work is done before the machine is washed, in which event charging may be delayed, but this is the exception. Generally work may be done while the battery is being charged, and when charging is completed a street test is made if this is considered necessary by the foreman.

In this garage the charging of batteries is by current supplied by a motor generator set, and instead of the usual multiple switchboard or panel there are a series of panels along either side of the garage which are each arranged to charge four vehicles at a time. The panels are at regular intervals, and at either side of each panel are two leads for charging, as is shown in the accompanying illustration. These are directly back of the machines stored in the spaces indicated by the numbers on the walls, and it is but a few feet from any of the four machines charged at any given panel, so that a great deal of time in reading instruments is saved for the man charging.

The original installation for charging consisted of five motor generator sets of 120 volts of various capacities, and by these current is supplied to each of the charging panels or stations. By placing both switches of each circuit in an upright position a current of 80 volts is available and by placing them in a downward position, a current of 120 volts is obtained. If it is desired to reduce the amperage below the normal this is accomplished by cutting in on the circuits with the rheostats shown with each panel.

A new charging system is being installed that will be in operation in a short time—perhaps a few days—and this will consist of a Westinghouse three-piece apparatus. The motor or centre unit is a 4150-volt synchronous motor, 285 horsepower, 60-cycle three-phase, 46 amperes a phase, 900 revolutions a minute. The generator at the left is a 145-kilowatt 120-volt 1210 amperes, and the generator at the right is rated at 45 kilowatts, 80 volts, 262.5 amperes. By using this installation a combination is afforded that is very

Battery Charging Sheet, Which Requires a Daily Entry for Each Month, Showing the Specific Gravity, Odometer and Charge Records, and the Relative Work Accomplished by Vehicle Miles, on Sheet Eight Inches Length and 11 Inches Width, Printed in Black on White and Ruled Longitudinally with Blue and Transversely with Red; Perforated for Loose Leaf Binding.

economical, as the pleasure cars do not require more than 80 volts, and it is unnecessary to lose the difference in voltage that would be lost were but one large 120-volt generator used.

It will be noted that the panels are unusual in that they have but one indicating instrument, an ammeter, and no voltmeter. The switches afford a variance in the amperage of the current, and this is shown by the ammeter, but the voltage of the batteries is learned by gravity test. The battery of a machine is drawn out of the cradle so that a cell can be selected for a pilot, and during the period of charging the specific gravity of the cell is taken at frequent intervals, and the condition of the charge is accurately known by the reading of the hydrometer. The amperage is continued at the initial rate until it is shown by the gravity of the electrolyte that it should be reduced, and then it is maintained at the lowered rate until the cell has reached the gravity that indicates the charge is completed. It is maintained that the constant observation of the pilot cell gives a very accurate knowledge of the condition of the battery and that less current is used than when the readings of a voltmeter are accepted. Besides this it is possible to detect conditions that might not otherwise be known until a considerable loss of capacity made it evident.

The battery charging sheet gives the name and address of the owner of the machine, the date, make of vehicle, make, number of cells, number of plates and number of trays and the type of battery. There is an entry made for each day of the month, and this gives the specific gravity of the battery as shown by the pilot cell on leaving the garage and the temperature of the battery, and similar readings are taken when the machine returns, and the difference in gravity is noted, with the total and trip readings of the odometer. The record of charging shows the time when it was begun, the amperage, the time when it was reduced and the amperage reduced to, and the condition as to "gassing." There are three entries possible for each day against any one date, which is sufficient to provide for any condition that may arise. Once each month each vehicle battery is given an overcharge and then each cell is tested for specific gravity and the electrolyte is equalized, so that the battery is brought to its highest efficiency. On the reverse side of the charging sheet is noted the date, time, temperature and amperage of the battery, and the last three items are entered each time the gravity of each cell is taken, and no less than 16 readings are required, which indicate with great exactness the condition of each cell during the entire period of charging.

It will be seen that the charging sheet is a very interesting record and the method of charging requires

Reverse of Battery Charging Sheet, Used to Record Individual Cell Readings During the Period of Overcharge, Given Monthly. This Showing the Condition of the Battery and Its Units.

a thorough knowledge of the battery that must insure an unusual efficiency. While it is possible that an accident might cause a damage that would result in loss of capacity, and necessitate a repair, the normal changes can be very closely followed and conditions anticipated from the facts of record.

The maintenance service of the company is worked out on the basis of a year's contract, and the charges provide for every expense in connection with the use of a vehicle save insurance, painting and repairs resultant from accidents beyond the control of the company. It includes storage, washing, polishing, charging, repairs of all kinds resulting from wear, adjustments, overhauling, battery restoration, and oiling, greasing and other attention, covering both labor and material. The year is taken as 300 working days, for one week is necessary to thoroughly overhaul the machine and repair and restore it. But to be able to secure this service a machine must be new or as good as new. When the contract is made the company guarantees to have the machine ready for use each working day morning, and where there is failure to have the vehicle ready the company will rebate the maintenance charge for the day. Where the time is lost through a fault beyond the control of the company then the charge is continued and the owner suffers the loss.

The maintenance charge is as follows:

Vehicle	A Day	A Year
700-pound wagon	$3.00	$900
1,000-pound wagon	3.50	1050
2,000 pound wagon	4.00	1200
4,000-pound wagon	4.50	1350
7,000-pound truck	5.75	1725
10,000-pound truck	6.25	1875

In addition to this the owner must consider his fixed charges, which include interest on investment, depreciation, taxes, insurance, and to which is added the wages of the driver and the cost of accidents for which the driver or others are responsible.

The battery rental service will be without reference to character or type of vehicle so long as it is built for a standard size of battery. The company will sell a vehicle without a battery and will make contract by which, for the payment of a service charge (which must be paid whether or not the machine is used), the owner can have a fully charged battery installed in his wagon as often as he desires, and when the charge is exhausted or well reduced another may be secured, so that the machine may be kept in operation constantly if required. Payment will be made on the basis of miles the battery is driven, this to be indicated by the odometer on the vehicle, and the greater the mileage the less the battery cost a mile. The time required for changing batteries will be comparatively brief, from three to five minutes being necessary unless something unexpected causes delay. With this service the owner will be relieved of all thoughts of batteries, for he has nothing to buy, nothing to maintain, and he is assured of a practically constant mileage and no loss of capacity through deterioration.

The battery rental service has been carefully worked out from known facts and data, but the details as determined may be changed or modified when it has been given the test of operation, and its cost is known to the company. From the viewpoint of the vehicle owner, however, it has everything to recommend it.

There are now stored in the garage 17 electric wagons and trucks, 12 electric pleasure cars, four gasoline pleasure cars and eight gasoline trucks, a total of 41 machines. The garage force consists of three men in the battery room, five mechanics and two "chasers," a total of 10, and the mechanics make repairs on all vehicles that come in besides the machines given service on a monthly contract. The night force includes one batteryman, one "chaser," two washers, one man who oils and greases cars and trucks, and one general repairman.

EDISON AWARDED RATHENAU MEDAL.

Inventor Honored for His Services in Safeguarding Workers by Perfecting Battery.

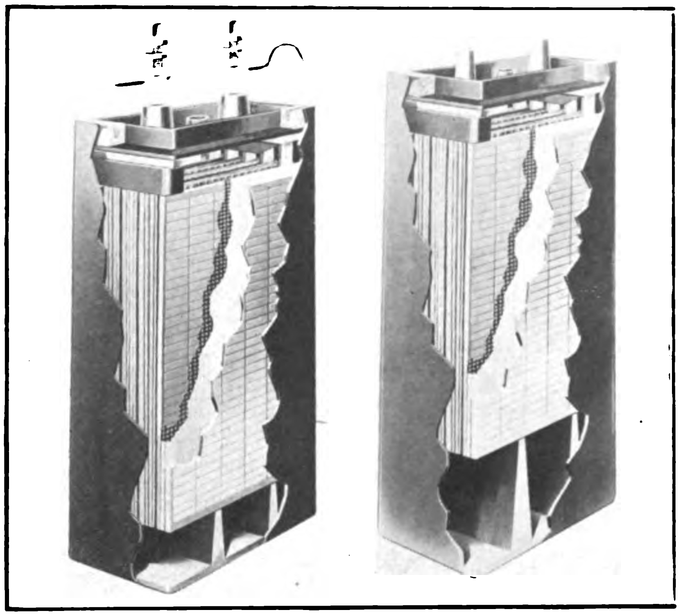
The Rathenau medal, last summer placed at the disposal of the American Museum of Safety by the Allgemeine Electricitats Gesellschaft of Berlin, to be awarded annually for the best device or process in the electrical industry for safeguarding life and health, was bestowed upon Thomas Alva Edison at a meeting of the museum held at the United Engineering Societies building, 29 West Thirty-ninth street, New York City, the evening of Jan. 23. The inventions for which Mr. Edison was honored are the results of his latest experiments with the storage battery, and recognition of his application of his battery in new forms with special adjuncts in relation to safety in mines, tunnels, work under water, in factories where explosives are made, powder magazines and where explosive gases are generated or used. It is believed that the application of the battery in this field has reduced the hazard to workers fully 100 per cent.

The Rathenau medal was presented to Dr. Emil Rathenau, president and founder of the A. E. G., on his 70th birthday with the felicitations of Kaiser William for his services in the field of electro-technics. He introduced electric lighting into Germany and is an old friend of Mr. Edison. One medal is struck each year from the original die for the museum to award. The Scientific American medal, the Louis Livingston medal and the Travellers Insurance Company's medal were also awarded at this meeting, the last to the New York Edison Company for making safer the electric industry. President Arthur Williams presided and the awards were made by Prof. F. R. Hutton, chairman of the jury of awards.

The First National Bank of Boston has recently purchased its second White truck, made by the White Company, Cleveland, O. This machine, which is rated at 1500 pounds, is electrically lighted and all its locks are operated from the driver's seat, so that entrance is impossible without the knowledge and consent of the man at the wheel.

NEW FEATURES OF LBA STORAGE BATTERIES

THE Willard Storage Battery Company, Cleveland, showed at Madison Square Garden an improved battery cell for which extreme accessibility is claimed.



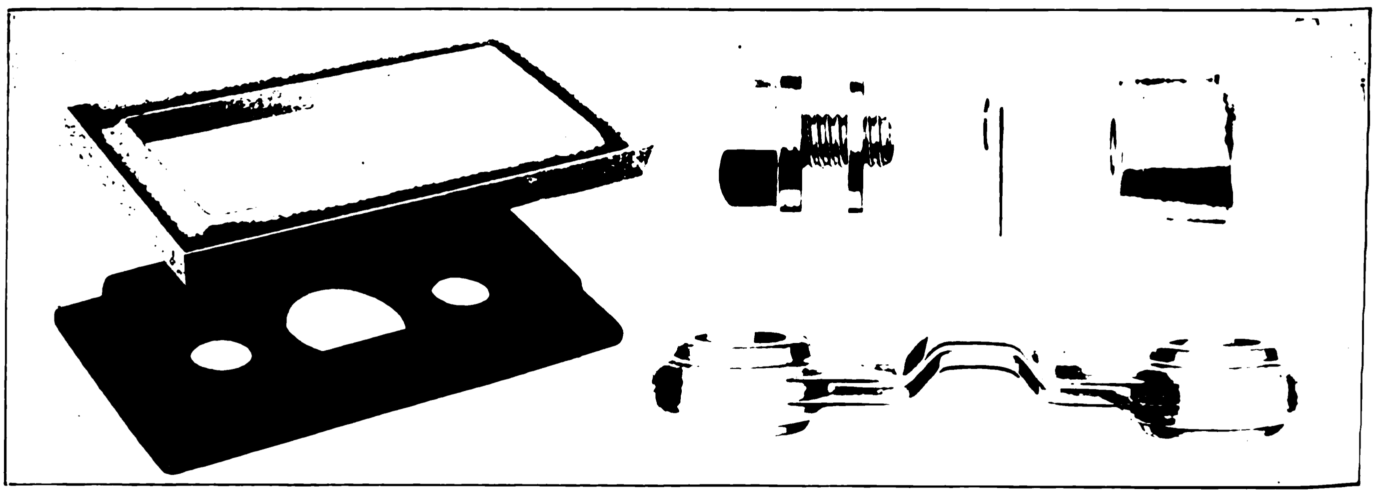
LBA Battery Cells: At Left, Low Bridge Type with Bolted Connectors; at Right, High Bridge Sealed Cover Construction.

One feature is a return to the use of bolted connectors, which type was originally used by battery makers and rejected because of the corrosion from the electrolyte, and another is an improved form of cover which consists of a hard rubber plate and is used with a gasket of pure gum.

The custom has been for battery makers to seal the cells with a pitch or asphalt compound, heated to fluidity and poured into the top of the jars. When this cools it is necessary to cut or break it to expose the element, and in repair or restoration the seal must be replaced and the connectors "burned," which means melting the lead, so that this will be a solid piece when cool. Corroded matter will, if permitted to accumulate, cause a short circuit or will insulate conductors, and it was to prevent this that the "burned" connectors were used. It is evident enough that time must be taken to cut the lead and to remove the sealed cover, while it is also necessary to have a tank of hydrogen gas or some other source of intense heat and the apparatus to "burn" the lead.

The condition of the battery can always be best determined by careful observation, which is not possible with the sealed type without cost for labor and perhaps material, although hydrometer readings may be made to test the electrolyte. It is maintained that with the LBA batteries the cells may be opened by the removal of the bolts and connectors and lifting the hard rubber covers and the soft rubber gaskets, minimizing time and labor and eliminating the special facilities for and the expert attention required for lead burning.

The jars are built with heavy walls to resist breakage, and with standard and extra high bridges to support the element. The latter construction affords more space for sediment to deposit in the cell. Vent plugs are made to condense the gas from charging by breaking the bubbles before they escape. The LBA plates are made by a process that insures the strength and service required for electric vehicle propulsion. Types J and K of the LBA vehicle batteries have heavy plates of standard thickness and are assembled in elements of from five to 21 plates. These types are made with the new bolted connectors and rubber gaskets, or with the old type connectors and sealed covers, and with either high or low bridge jars. Types L and M have medium plates and are assembled in elements from seven to 23 plates, the capacity of the cell being more for the same weight and bulk than with types J and K. These are also made with the low and high bridge, and it is held that the latter form will not short circuit from sediment during the life of the battery. Types N and O have light plates and the elements are composed of from seven to 27 plates. It is claimed the capacity is greater than the other and affords increased mileage. The company also produces batteries that are especially adapted for lighting and starting purposes.



LBA Battery Construction: At Left, Hard Rubber Cover and Soft Rubber Gasket for Quick Sealing of Jar; at Right, Type of Cell and Bolt Connector Affording Greater Accessibility.

ELECTRIC VEHICLE PRACTICE.

Wagons and Trucks of Today the Combined Development of Motor, Battery and Chassis by Scientific Engineering and Patient Experiment—the Result of Concentration on Practical Standard Types Adapted to Varying Conditions.

By William W. Scott.

THE development of the electric vehicle has been accomplished by numerous factors, and while it is true that design has been worked out purely

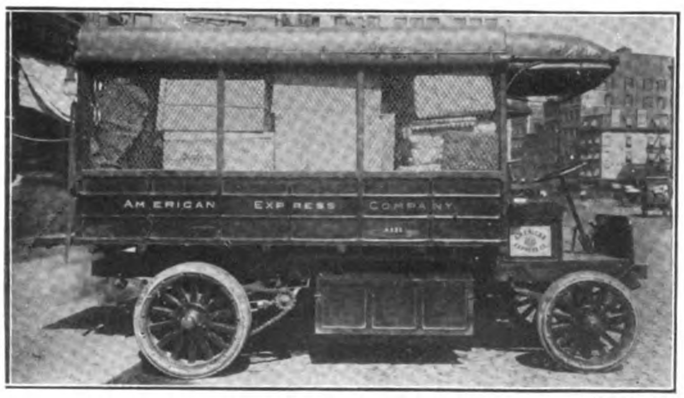
Vehicle Equipment Truck, Double Motor Pedestal Type, Built in 1901—An Ornate Construction as Compared with Wagons of Today.

through engineering experience, it is also a fact that motors have been perfected by concerns having the services of the best experts in America, if not in the world, while the batteries have been brought to an equally high efficiency through the endeavors of men internationally recognized for their ability. To illustrate, the same types of motors used for propelling vehicles have been so generally used for prime movers that commercial necessity impelled the greatest care and skill in their production, and justified the constant observation and experimentation of the best of expert engineers. Railway and street railway propulsion established the need of the type of motor used in carriages and wagons, and these have been so improved and refined that it can be said they can be used for years with no other attention than lubrication of the bearings and adjustment of the commutator brushes. Very recently the writer noted in New York the commutator of a motor that had been used daily in a truck for more than three years, and during that time had not been polished. The metal was in better condition than the day the motor was installed in the machine, and it has been driven more than 30,000 miles. This is an example of the endurance of electric motors.

The initial experience of the General Electric Company, which is probably the largest maker of motors of the world, with vehicle motors, covers a period of more than 16 years. The possibilities of the electric motor was understood and Herman Lemp of the company, who was at that time located at Lynn, Mass., decided to experiment exhaustively. In March, 1897, the work of building a six-passenger vehicle was started, and the machine was given its first trial July 2 of that year. It is desirable to describe briefly this machine, for it was an important factor in the industry.

The battery was underslung between the wheels, and the cells were always connected in series. The drive was through the rear axle with a single reduction through herringbone gears, enclosed and running in oil. The motor was designed for high efficiency on overloads regardless of weight. The armature had two windings with two commutators, and these windings could be connected through a controller in series or in multiple. The motor was spring suspended from the body at one side to lessen shocks in starting. The front axle was divided and the wheels were steered by a lever movement through cranks. The controller was very accessible, being located under the seat. A single handle operated the controller drum, the handle operating in a Z-shaped slot to prevent an unintentional reversal.

The controller had six positions—three forward, one backward and two at rest. In the first forward position the windings of the armature were in series; in the second forward position the windings and the armature were in multiple, and in the third forward position the field was cut or divided. In one of the rest positions an electric brake was used. The direction of the motion of the controller handle indicated the direction in which the carriage would move. Attached to the controller was a brake switch which could be thrown open by the application of the foot brake. This could not be closed until the handle had been brought to zero, when it would automatically restore the circuit. A removable key under the con-



Atlantic Truck, 3.5 Tons, a Typical Standard Construction, with Single Motor and Double Chain Reduction.

troller handle permitted the operator to open the circuit when leaving the vehicle, this preventing movement of the machine by unauthorized persons. An ex-

panding brake was used on the rear wheels. On a single battery charge the radius of movement was approximately 35 miles. The vehicle was at different

Commercial Two-Ton Wagon, Driven by Two Motors and Concentric Gearing That Gives the Necessary Reduction.

times equipped with pneumatic tires on wire wheels, and solid rubber tires on wooden or artillery wheels, the latter being finally adopted as most efficient.

It is exceedingly probable that were motor development dependent entirely upon the number used for vehicle propulsion but comparatively little progress would have been made, but commercial necessities impelled a constant endeavor to improve and perfect. In developing the motor the precise engineering data available have been of extreme value. The manufacturers had the service of the best of scientists and all that could be desired for laboratory and other equipment, and research and experiment was systematic and with definite results. As may be understood, the utilization of the enormous possibilities of electric power was dependent upon the economy of its use, and the main factor was the efficiency and dependability of the motor. Service in a large diversity of uses was considered in experimentation.

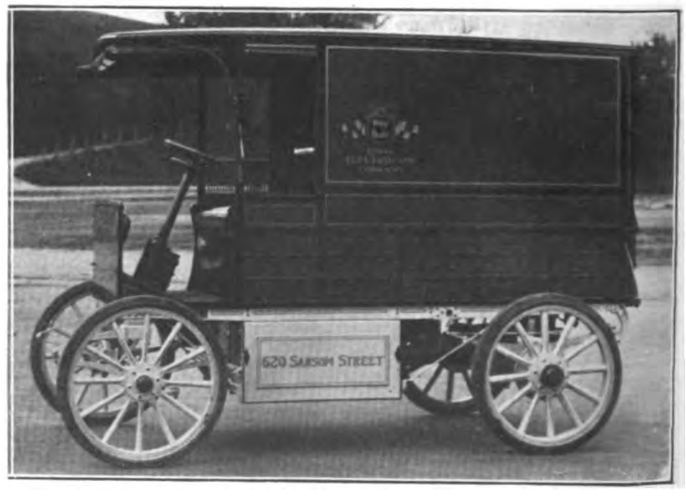
The policies of the large electric manufacturing companies may be said to be very nearly uniform, and so far as is possible they seek to obtain the largest measure of results from their manufacturing rights. Progression and perfection are the objects of these organizations. The motors of years ago were well built and efficient, but these have been remarkably improved so far as longevity and endurance are concerned. It is impossible to predict the life of a motor given good care and well maintained, but it is a long period of years with constant service.

Electric vehicle batteries were not developed to the same extent as were the motors because there was not the demand for them, and neither was there the same resources of manufacturers with reference to development, for experimentation was costly and electric battery engineering had not advanced. There were two main purposes, the one to secure capacity and the other to insure endurance. It is not to be assumed that these could be attained at will and years were required to develop batteries that were considered as satisfactory. The first batteries were of the acid or lead type and to have capacity they were necessarily heavy, and as this was a load that must be carried the usefulness of the vehicles was proportionate to the weight and the power stored. Obviously a battery of large capacity would reduce the vehicle load because of its weight and to lessen the battery size would diminish the power and efficiency.

Not only this, battery cost was comparatively high and current could not be obtained save at prices that caused those considering these types of vehicles to hesitate, while experienced battery men were very few. Besides these conditions the charging facilities were confined to an occasional central station. It is extremely probable that had the development of the storage battery been through the use of vehicles alone comparatively little progress would have been made, but the value of electric energy for other purposes stimulated the research and experiment that brought about constant development.

The chassis builders first adapted animal vehicles to their needs and from these bases developed carriages and wagons as judgment dictated. The pioneers of the electric automobile were enterprising, capable men, and their works were remarkable from many points of view, but often conditions beyond their control militated against success. There were numerous constructions that were sound from engineering standpoints, but the uncertainty of the people as to the qualities of the machines and their capacities made the market precarious and without promise for those who built vehicles. It was not possible, however, to improve the machines without continued test and this meant for each designer a process of elimination and constant observation. There never was in the history of the electric vehicle what might be called enthusiasm for its use. The first machines were conceived for pleasure and were literally toys for persons of means, their chief recommendation being safety and comfort.

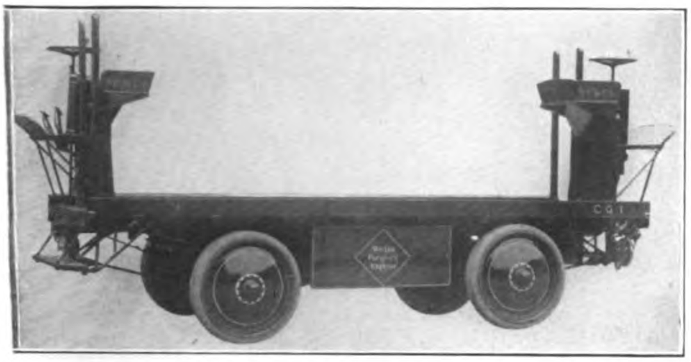
In America, at least, the initial wagon adapted to



Commercial 1000-Pound Wagon, This Being the First Electric Machine Built with a Worm Drive.

service purposes was built by Andrew L. Riker, and it may be said that Mr. Riker was the first to practically develop the electric for freight carrying. But

it was years after Mr. Riker turned to the building of steam and then gasoline automobiles that the qualities of the electric machines were realized. The elec-



Couple-Gear Four-Wheel Driven Truck, Each Wheel Containing a Motor with Its Armature Shaft Driving Pinions That Engage with Racks in the Inner Rim Peripheries.

tric wagon was first discredited and very generally rejected because of conditions which the manufacturers could not influence or control. It took years of patient endeavor and education of the people to make understood the practical economy and longevity of the vehicles, and it was necessary as well to unify the interests of the manufacturers of motors, controllers and appliances, of batteries, of chassis and the central stations to bring about the concerted development that has been realized. It was only when these factors were harmonized and systematic exploitation begun that the industry began to make progression that resulted in recognition.

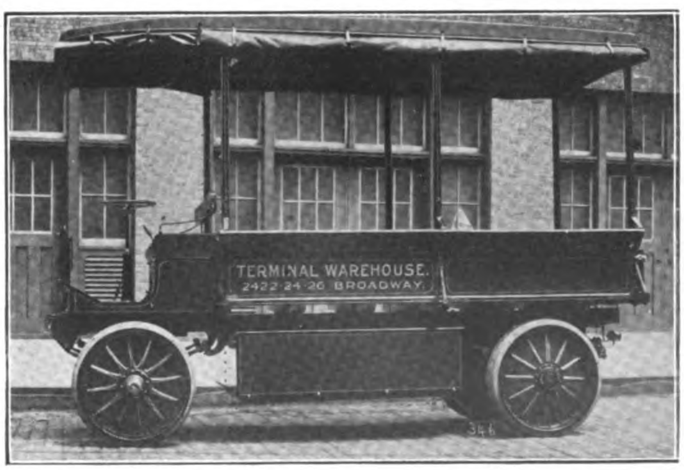
In the spring of 1898 the Riker 500-pound wagon was delivered to B. Altman & Co., which was followed by five others during the year. One of these wagons is now in use, and a Riker two-ton wagon delivered in March, 1901, has been used constantly since that time. It is possible to follow numerous instances of continual service, and generally of haulage that has tested the qualities of the vehicles to extremes. The history of the industry demonstrates that, as with the motor and controller, commercial possibilities brought about the development of the battery, and the chassis builders sought to improve their products with admirable judgment. The experience has generally been the perfection of a design, and generally each make has distinct characteristics which, while not varying from well established principles, are different adaptations.

The majority of electric vehicle builders of today have a single design and the machines vary in size. Others build two types and several build three, but with practically all the purpose is to standardize and perfect. Speed has never been a material quality sought by electric vehicle designers. Pleasure machines have been made desirable because of their especial qualifications for town and city use and their luxuriousness. There has been and probably will be for a long time to come, a limitation to the demand because of battery limitations, but for freight carrying and for purposes where a stated work is required the electric wagon has qualities that commend it. The formation of the Electric Vehicle Association of America for the purpose of exploiting the possibilities of the electric wagon has been exceedingly productive, for this organization has undertaken to crystallize public attention on the machines and the work for which they can be used.

The different bodies of representatives of central stations have also taken up the burden of interesting the stations generally in the commercial possibilities of the electric wagon and the promotion of their use, and the most practical method has been found in the co-operation of all these interests. Within the past two years a considerable number of central stations have included in their organization men who have actual knowledge of electric wagons, and who are developing business to a greater or less extent, doing the same missionary work that has so wonderfully increased the use of electricity for lighting and power. Others have co-operated with the representatives of manufacturers and agents for machines, and still others have become agents for the sale of wagons. There is nothing illogical to the policy and each month the number of central stations using electric wagons and promoting their use has increased.

The attitude of the electric vehicle industry, while competitive, is logically co-operative, and it may be stated that without exception service and not initial purchase price has been the object of the makers. By this is meant that the chassis have been carefully developed to insure constant work for years, and the prices have been established when assurance could be given that all of the requirements have been met. The electric wagons cannot be regarded as cheap, but when the period of service is measured by the cost it must be admitted they have the economy that prompts their use.

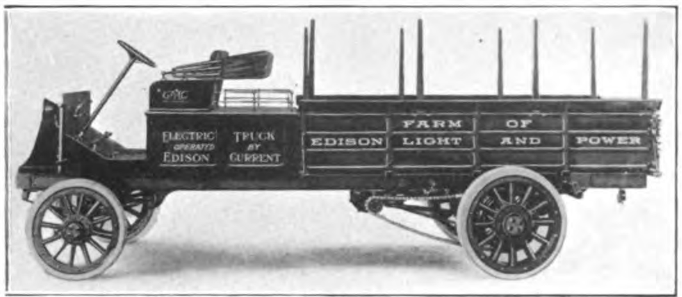
When comparisons are made of electrics of the earliest constructions and those of today, it will be noted that principles have varied but little, but there has been a remarkable perfection of designs, construc-



Walker Truck, the Motor Being Housed in a Casing That Serves as a Rear Axle and the Power Applied Through Spur Concentric Gearing.

tions, materials, workmanship and finish. The automobile industry created a demand for special metals, which have been used to afford greater strength and

endurance as well as lessening weight, the batteries are lighter and the capacities increased, and the chassis engineers have minimized frictional loss of power and also have protected the moving parts against wear.



G. M. C. Wagon, in Which the Power Is Transmitted by a Flexible Shaft Direct from the Motor to Countershaft.

Relative to vehicle installations, the sizes range from 500-pound to five-ton machines, and while there are those who specialize the lighter wagons only, the majority of the makers have produced a number of sizes up to five tons, while two firms making tractors have machines of this type with capacity of eight and 12 tons. The electric vehicles are driven by motors from storage batteries with the exception of one type, in which the current is supplied by a gasoline motor, this having an unlimited radius of movement. This machine is supplied as a tractor, if desired, and it is maintained that it affords the desirable qualities of both types.

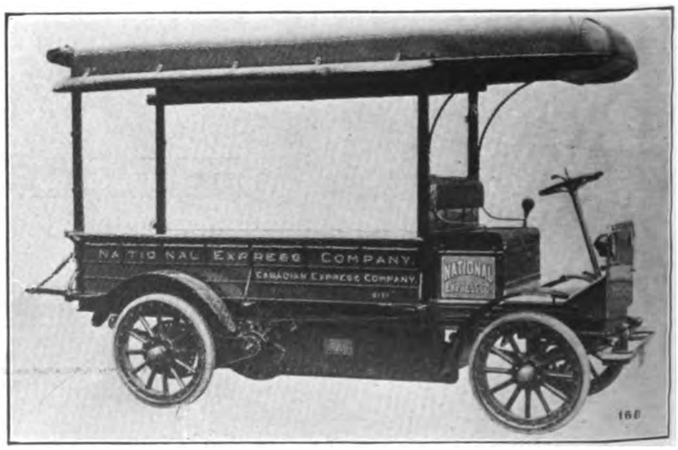
In the lightest electric service wagons the radius of movement is about 80 miles, this carrying a load of approximately 300 pounds the entire distance. The 500-pound wagons are rated at about 60 miles, and the 750-pound wagons at 50, while the other machines lessen in mileage to 35 in the case of the five-ton sizes. In the mileage rating of the wagons it should be remembered that this is to carry a load half of the distance over average streets and highways, but does not comprehend haulage over very steep grades or extremely rough roads. The battery capacity when the battery is new is considerably in excess of the rating, and with the acid or lead batteries there is a diminution in capacity that is proportionate to the number of charges and discharges. A battery may diminish in current output until it is not more than 5 per cent. of the maximum, but this will result from abuse or constant work. The diminution of battery capacity applies to the lead or acid type only, for there is no actual knowledge of the reduction with the alkali or nickel-iron cell. There is undoubtedly a loss, but this is so slow that no data have yet been compiled that will make possible an accurate estimate. It is not purposed to discuss the subject of batteries at this time, but the intention is to point out that the ratings are entirely conservative, and that for consideration of an installation these figures need not be discounted.

The range of service is not restricted with electric wagons so far as the character of freight to be carried is concerned. The designs are such that body equipment can be readily adapted, and bodies are more generally built by the manufacturers than for other types of machines. It is possible to use the electrics for any purpose that may be desired. One manufacturer is building each chassis in three lengths to afford different body lengths, but this instance is the exception, although there may be special construction when required.

With reference to bodies there is a very general disposition by the makers of chassis to insure against excess sizes of equipment and to equalize so far as possible the loads that may be carried, one manufacturer, at least, refusing to sanction the sale of a machine without first approving the body. This may appear to be extreme care, but it is practical insurance against a condition that might result in eventual damage and dissatisfaction.

There has been a very general use of standard types of bodies with electric wagons from the fact that express companies and concerns having large delivery equipment, such as department stores, breweries, packers, food product makers and the like, prefer to continue a uniform and distinctive appearance, because of the advertising value of machines that may be recognized at a glance. As with other forms of motor wagons, there are innumerable instances of special service bodies, but these are chosen with reference to their striking or individual design or from the fact that an unusual work is to be done.

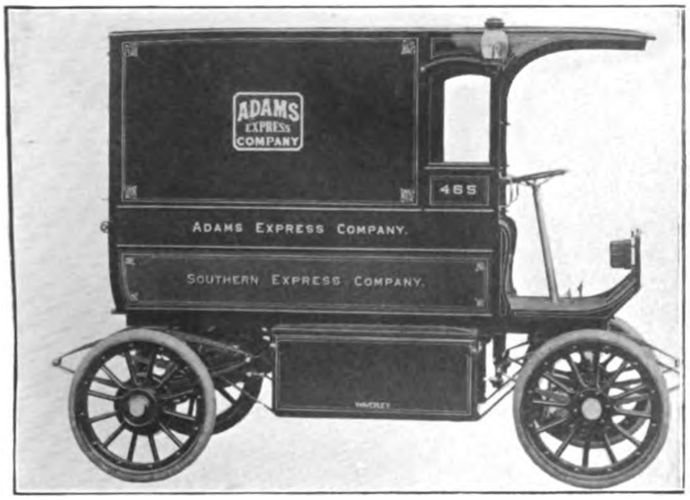
When electric machines were first used there was evident desire to use them with full realization of their advertising value, and this will be borne out by the illustration which shows the highly ornate truck built by the Vehicle Equipment Company in 1901 for the Germania Roofing Company. This was essentially a show wagon, and while it has a design that would stamp it as a service machine, the finish and ornamentation was such as would cause a present day observer to wonder why there was an apparently unnecessary expense incurred, when it was considered that the vehicle was to be used for purposes of general haulage.



Detroit Delivery Wagon Driven by a Single Motor with a Double Chain Reduction, Using an Edison Nickel-Iron or Alkali Battery.

In many instances there has been but little if any change in general proportions of bodies when animal and motor vehicles in existing installations are exam-

ined. By this is meant that the sizes of the old equipment could be retained so far as desired and the freight load distributed as comprehended in the design



Waverley 1000-Pound Wagon Driven by a Motor with First Reduction by Silent Chain to a Countershaft and Thence by Herringbone Gears to the Floating Rear Axle.

of the chassis. A casual examination of the bodies of wagons owned by large express and transportation companies will impress one with the fact that so far as possible the characteristics of the animal vehicles have been retained for two purposes, the one being the advertising value from public knowledge of appearance, and the other the construction has been proven to be substantial and economical.

DEPARTMENT STORES ABANDON HORSES.

Chicago and Indianapolis Firms Install Equipments of Waverley Wagons.

Mandel Brothers, Chicago, Ill., and L. S. Ayers & Co., Indianapolis, Ind., have abandoned delivery by horses and both firms have installed Waverley electric wagons. The change was made practically at the same time and at the opening of winter when the work might be regarded as heaviest of the year, because of the holiday trade. The service in either instance was faster and better than ever before. The Mandel equipment consists of 10 1000-pound shaft driven machines with special bodies, these beirlg built large enough to meet any requirement. Five wagons were equipped with batteries affording 60 miles driving on a single charge, and the other five with batteries of from 75 to 100 miles single charge capacity. The maximum speed is 14 miles an hour. The firm had previously used for several years both electric and gasoline machines.

Ayers & Co. installed six 1000-pound shaft driven delivery wagons and a one-ton delivery wagon for the furniture department. These machines are driven by drivers from the horse wagons, who were given instruction for a few days in the use of the electrics. The automobiles replaced 12 single and two two-horse wagons. The time of delivery has been shortened and on a suburban route one wagon does the work of two wagons, four horses and two men. The average mileage has been 35 with a maximum of 67. The average number of packages delivered during the rush season was 241 and the maximum number was 462. The daily cost of the use of this equipment has been estimated as follows: Operating expense, including garaging, charging, washing, polishing and replacement of parts, $2; fixed charges, including interest, depreciation, etc., $1.30, and wages, $2.50, this giving a total of $5.80.

NEW CARBURETOR FACTORY.

Milwaukee Inventor Decides to Locate Production Plant in Southern California.

A new factory for the manufacture of the Jensen carburetor has been established at Los Angeles, Cal., being located at 2413 South Grand avenue. The inventor is A. Rasmus Jensen of Milwaukee, Wis., who recently, with Mrs. Jensen and Otto S. Nick of Milwaukee, drove from that city to Los Angeles to test the vaporizer over the various mountain and valley roads.

Mr. Jensen decided to locate his factory in California and the plant was secured upon his arrival at Los Angeles. The carburetor is said to be absolutely automatic in its action, adjusting itself to heat and cold and to all changes of altitude, as well as to low and high speed of the motor. The mixture is varied by thermostat, which expands and contracts and thus governs the volume of gasoline and air that may be admitted to the intake manifold.

The Waverley Electric Wagon Delivery Service of L. S. Ayers & Co., Indianapolis, Ind.

FACILITIES MEAN EFFICIENCY.

Special Loading Equipment Large Factor in Delivery Service of Large Concern.

M. A. Newmark & Co., a large wholesale and importing firm at Los Angeles, Cal., utilizes 11 G. M. C. gasoline trucks of 3.5 and five tons capacity, which have replaced a large horse wagon equipment. The machines make practical a delivery that was not previously possible. The company, with the installation of the trucks sought to secure the largest measure of service, and to do this a number of wheeled bins were built. Two of these may be carried on the deck of each truck.

The warehouse of the company has an electric trolley system on each floor that converges at the elevator, and on the elevator is a continuation of the overhead rail, so that after the bins are loaded they may be carried by the trolley to the elevator and lowered to the first floor, where they are rolled onto the loading platform. As fast as the bins are filled they are sent to the platform, where they are in readiness when the trucks arrive. Empty bins are rolled from the trucks and replaced by those loaded, and the machines may be then driven away with very little loss of time. It is maintained that the company has increased the efficiency of its delivery 30 per cent. by the installation of the loading equipment.

The G. M. C. Gasoline Motor Truck Equipment of M. A. Newmark & Co., a Los Angeles, Cal., Wholesale and Importing Firm.

WILL BUILD WAGONS AND TRUCKS.

Edison Electric Vehicle Company of America Organized at Lawrence, Mass.

The Edison Electric Vehicle Company of America, Inc., has been organized at Lawrence, Mass., and has announced that it will build a complete line of electric wagons and trucks, the sizes being: Seven hundred and fifty pounds, known as model.8; 2000 pounds, known as model LLB; 4000 pounds, 7000 pounds and 10,000 pounds. The machines are built to a standard design and are fitted with Edison batteries.

The first vehicles produced are the smaller types and the larger will be built within a comparatively short time. Later on it is possible that pleasure vehicles will be manufactured.

MOTOR TRUCK CLUB BREAKFAST.

Members and Guests Hear Talks on Practical Subjects from Leading Factors in Industry.

One of the events incident to the show of service wagons at Madison Square Garden and Grand Central Palace was the breakfast given by the Motor Truck Club, an organization composed of men active in the power vehicle industry and trade, at its headquarters, 1845 Broadway, the morning of Jan. 21. Because of the demands of business it was believed best to have the gathering prior to the opening of the show for the day, and this plan brought together a company of nearly 300 men representing all sections of the country.

The breakfast was of six courses, and following it was an address of greeting by President D. C. Fenner, announcements by Secretary Ellis L. Howland, and a series of speeches, the subjects and speakers being: "Production," F. F. Beall, Packard Motor Car Company; "Advertising and Selling," P. D. Wagoner, president of the General Vehicle Company, whose paper was read by E. W. Curtis, Jr.; "Operating Motor Trucks," Elisha Flagg, Jr., general manager of maintenance of the American Express Company; "Motor Truck Service," George H. Duck, general service manager of the American Locomotive Company; "Past, Present, Future," Walter Wardrop, editor of Power Wagon.

The subjects were all timely and were well prepared, and the views and conclusions were especially interesting. The speakers dealt with practical data and facts obtained through experience and observation, relating to the marketing and utilization of power vehicle of all classes, and were heard with keen attention.

An article in the January issue of MOTOR TRUCK on "Motor Truck Springs and Their Work" was illustrated with sketches, which were modified by the author from certain illustrations in a book on "Leaf Springs, Their Characteristics and Methods of Specifications," published by the Sheldon Axle Company, Wilkesbarre, Penn. The absence of credit for reproduction from so excellent an authority prompts MOTOR TRUCK to make this acknowledgment.

Municipal Service Equipment

BOND ISSUE IN TOLEDO.

Plans Under Way for the Complete Motorization of Several City Departments.

The city council of Toledo, O., has passed an ordinance providing for a bond issue of $200,000 to be used for motorizing the fire department. Bonds are to be issued and bids for the motors asked for. In addition to the fire department the money made available, which will total $270,000 with the sale of the horses and apparatus, will enable virtually every city department to be motorized.

A motor truck will be bought for the fire alarm telegraph system, the electrical, building and smoke inspectors will be furnished with machines and several will be allotted to the police department. When this programme has been completed the motor equipment of Toledo will be second to none in the country.

KISSELKAR FOR QUINCY.

Massachusetts City Decides Upon Six-Cylinder Machine Made in Wisconsin.

An accompanying illustration presents the new combination hose and chemical engine made by the Kissel Motor Car Company, Hartford, Wis., for the fire department in Quincy, Mass. The entire vehicle is of special construction, in that the body, which was built to specifications supplied by the Quincy officials, is mounted on a KisselKar two-ton chassis and fitted with a 60 horsepower, six-cylinder motor.

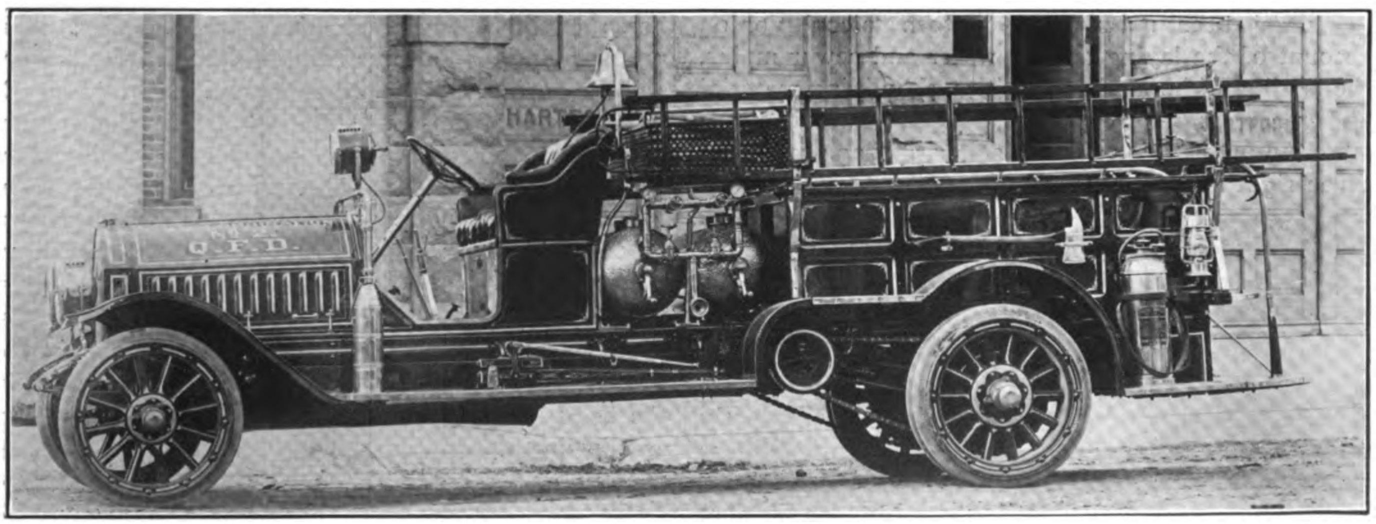
The equipment includes two large chemical tanks and the usual allotment of chemical and regulation fire hose, axes, extension ladders, hand extinguishers, lanterns, searchlight and tools. The assembly is particularly pleasing and is one in which the people of Quincy will take pardonable pride.

Similar equipment has been delivered recently to the fire departments in Salida and Sterling, Col., and the Kissel company finds the construction of apparatus of this nature is becoming a decidedly important branch of its work, which also includes the manufacture of Kissel Kar pleasure cars and commercial vehicles of all types.

POPE-HARTFORDS ARE EFFICIENT.

Fire Chief in San Francisco Satisfied That Motor Driven Apparatus Is Superior to Horses.

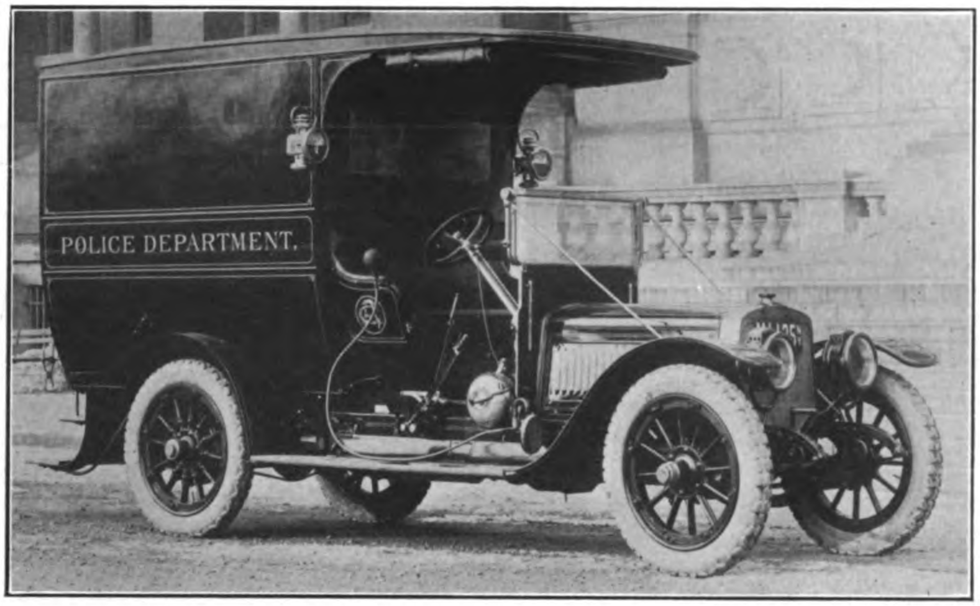
In providing automobile transportation to promote the working efficiency of various municipal departments, San Francisco ranks among the most progressive cities in the world. By the installation of motor driven vehicles the fire, police, education and health departments have within the last four years saved substantially in both time and money in conducting their affairs. Taking the fire department as an exam-



KisselKar Six-Cylinder Combination Chemical and Hose Wagon Recently Delivered to Fire Department in Quincy, Mass.

ple, San Francisco now has in service a special double 80-gallon tank chemical and a hose wagon designed to move a heavy cargo of water hose and squad of 10 men. A six-cylinder touring car also is used by Assistant Chief Maxwell and four roadsters have recently been put into commission by the battalion chiefs. These machines are all Pope-Hartfords, made by the Pope Manufacturing Company, Hartford, Conn.

Fire Chief Murphy, in speaking of his experience with the motor driven vehicles, says: "We are going to motorize the whole department as soon as we can, so satisfactory has been the service we have had from the motors we now use and I expect to be able to do better with less pieces, proportionately, in the future, because of the fact that they are motor driven. We will get more service than we could with the horse drawn apparatus. In respect to speed in getting to a fire, ease of handling cars in crowded streets, ability to stop quickly, and in fact general all around efficiency,



Six-Cylinder Lozier Chassis Mounted with Patrol and Ambulance Body for Police Department in Augusta, Ga.

motor fire pieces I have found to be far ahead of the old style of horse drawn fire fighting machine. Although San Francisco's streets during the past few years have been in a more or less torn up condition on account of the laying of new water and sewer mains, the hauling of immense quantities of building material and general street rebuilding, the fire motors have stood up under this strain in splendid shape and have given right along the very best service possible."

AUGUSTA POLICE PATROL.

Six-Cylinder Lozier Chassis Mounted with Combination Body for Southern City.

The police department in Augusta, Ga., recently took delivery of the Lozier patrol and ambulance shown in an accompanying illustration. The chassis is fitted with a six-cylinder motor and is the product of the Lozier Motor Company, Detroit.

The latter is of new design, and is arranged to accommodate 10 persons beside the driver and attendant. The appointments are thoroughly in keeping with the work the machine will be called upon to perform, and are modern in every particular. These include a stretcher and other first aid apparatus, so that the vehicle always is available for ambulance purposes at an instant's notice.

WATERBURY COMPARING COSTS.

Experience with Motor Fire Apparatus Such as to Convince Mayor of Its Economy.

Attention has been directed to the conservative estimate of Mayor F. T. Reeves of Waterbury, Conn., concerning the saving to be effected by the substitution of automobile fire apparatus in place of horse drawn vehicles. The mayor figures the difference in the cost of upkeep, which he says will pay the interest on a bond issue and wipe out the principal in 25 years. However, analyzing further it is found that there are other factors which make a much larger total. Each horse drawn apparatus requires one man to remain constantly with it to attend to the horses. Thus each horse vehicle costs $1000 a year for the man to guard it, while the motor apparatus can be left alone at any time and the city is saved an annual amount of $1000, which in 10 years would be more than enough to replace the apparatus should it become worn out.

The motor combination pump and hose wagon, which replaced two horse drawn pieces of apparatus at Waterbury, released two $1000 drivers for fire duty. A horse equipped engine company, when the engine is not pumping, holds three men in idleness, two drivers and the engineer. When it is pumping it draws an additional man from active duty to stoke the engine. When a motor engine is not pumping its whole crew is at work. When it is pumping it requires the services of one man only. This means an annual saving on a single piece of apparatus of a trifle over $3000 in salaries alone. Admitting, as has been claimed, that the life of motor apparatus will not be over 10 years, the total saving, $30,000, would replace the machine three times and still leave $3000 extra to be applied to the bond sinking fund. These figures are significant as showing the experience of a city that has already tried the motor fire apparatus with such success financially and otherwise, and that measures are being considered for a further investment of the same character.

BRIEF ITEMS FROM SEVERAL CITIES.

Cincinnati Buys Ten Combinations—One of the largest contracts made in many months for fire fighting machines of the automobile type was closed recently by the officials of Cincinnati, O., with the Ahrens-Fox Fire Engine Company of that city. By its terms the firm will furnish Cincinnati with 10 combination chemical and hose wagons to be delivered within 90 days.

Cleveland Adopts Electric Pumps—Going a step farther than most cities in their aims to introduce automobile fire fighting apparatus on a large scale, the authorities at Cleveland, O., are engaged on a plan for an electric pumping system patterned somewhat after that used at Berlin, Germany. Electrical connecting plugs are to be established beside the water plugs so that current for operation of the pumps may be obtained directly. These pumps are to be mounted on automobile chassis and to have a capacity for throwing 1000 gallons of water a minute.

Tampa Experimenting with Hudson—Tampa, Fla., has purchased a six-cylinder Hudson car, made by the Hudson Motor Car Company, Detroit, for Chief W. M. Mathews of the fire department. The machine is equipped with chemical extinguishers and other apparatus and carries five men, who often find it possible, because of the speed in getting to fires, to check them in their incipient stages. The success of the experiment may lead to further motorization of the department.

Gasoline Trucks for Electrical Department—The electrical committee of the board of bond trustees of Jacksonville, Fla., recently let the contract for furnishing complete three five-ton trucks for the electrical department of the city, to the International Motor Company of New York City, maker of the Saurer. The contract for furnishing an automobile for the use of the superintendent of underground construction was awarded to L. C. Oliver, who agreed to furnish a Ford touring car, made by the Ford Motor Company, Detroit, completely equipped.

KisselKar Reduces Fire Loss—The decrease in property loss since the general introduction of motor fire apparatus is noted by a report of the fire chief of Kankakee, Ill., who states that since his department placed in service a KisselKar hose and chemical wagon, made by the Kissel Motor Car Company, Hartford, Wis., the total loss in 57 fires has been only about $2500.

Hartford to Replace Horses—Realizing the need of motorizing all the fire apparatus in the city, the fire commissioners of Hartford, Conn., recently held a conference with the officials of the Pope Manufacturing Company of Hartford, maker of Pope-Hartford fire vehicles, and it was practically decided that an estimate would be included in the budget for this purpose. It is planned to put all the engines now in use on heavy chassis. The new tractor engine purchased from the American-La France Fire Engine Company, Elmira, N. Y., and recently tested, was accepted.

New Haven Shows Good Record—Figures compiled by the officials of the fire department in New Haven, Conn., indicate that the loss from fire during 1912 was only a trifle more than one-half that for 1911. These figures prove the advantages of automobile fire fighting apparatus. The loss in 1911 was $487,179 and in 1912 was $288,077. Speaking of this showing Chief Fancher said: "It highly pleases me that the fire loss this year is much lower than in 1911. This was accomplished by the motor wagons of the department and mostly by the squad wagon at Olive street, which has reached hundreds of fires in outlying parts of the city before any other piece of apparatus."

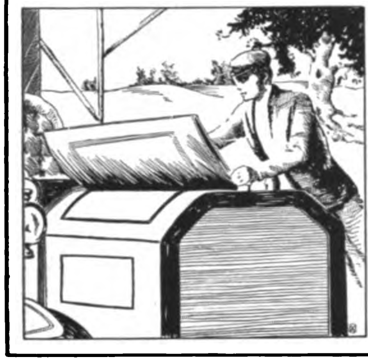
Mora Wagons for City Service—Recently the Mora Power Wagon Company, Cleveland, O., installed a Mora wagon of the open express type and 1500 pounds capacity, in the water works department in that city. Another vehicle of similar type was delivered to the city of Youngstown, O., where it is doing good work as a service wagon in the fire department.

Buicks for Boston Departments—The Buick Boston Company, distributor of Buick cars, made by the Buick Motor Company, Flint, Mich., has secured orders for roadsters from the Boston board of health, fire and wire departments. The fire department is especially well qualified to pass upon the merits of the Buick, as it has one model that has been driven over 100,000 miles and is in such condition today that an offer by the company to take the car over when the new one was ordered was refused by the city officials.

Second Knox for Lynn—The city of Lynn, Mass., which has had a Knox ambulance in its police service for several years, has just received another such vehicle from the Knox Automobile Company, Springfield, Mass. The machine embodies numerous improvements over the earlier models and the police officials are pleased with the service it is giving.

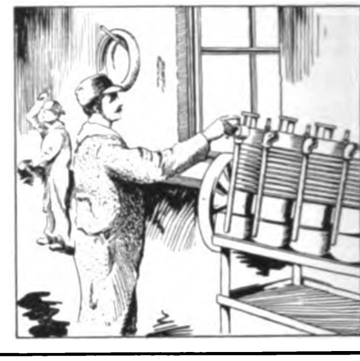
San Jose Buys a Knox—Samuel Crim, head of the Reliance Automobile Company, San Francisco, Cal., distributor for Knox vehicles, made by the Knox Automobile Company, Springfield, Mass., has received notice that a bid submitted by him to provide the city of San Jose, Cal., with a Knox combination chemical and hose wagon, has been accepted.

Garbage Wagons in Salem—Commissioner Edwards of Salem, Mass., who has charge of the street cleaning department, will request the aldermen to make an appropriation for 25 motor trucks to be used as garbage wagons, to take the place of the horse drawn vehicles now in use.



HINTS·FOR·PROPER MAINTENANCE

A Department for the Owner, Driver and Repairman.



CARLTON ALL-FUEL CARBURETOR.

The increasing cost of gasoline has resulted in more attention being given to heavy fuel carburetors, particularly abroad. A vaporizer which is of interest because of its small size and the utilization of a double-disc baffle plate member, is the Carlton all-fuel carburetor, an English design shown at Fig. 1. It is held that gasoline, benzol or kerosene may be vaporized successfully, although starting is not possible with the heavier fuel without resorting to heating.

As will be noted by the drawing, the vaporizer is of the valve controlled type and the principle of operation is said to be such that the several fuels may be employed successively without any alteration or adjustment, and with a clean exhaust.

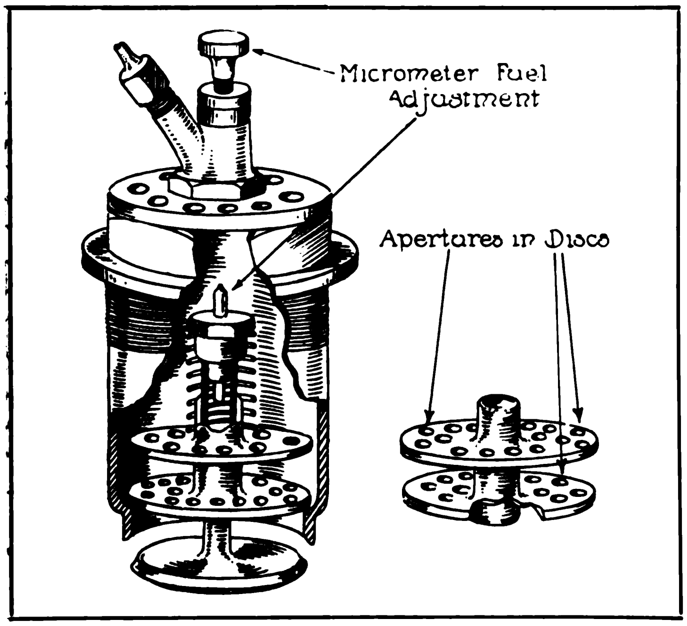


Fig. 1—The Carlton All-Fuel Carburetor, a Diminutive Valve Type of Vaporizer Having Double Discs.

The feed may be regulated by a screw arrangement and it will be noted that the needle, which is spring mounted in the top of the induction valve itself, sets directly into the bottom orifice of the fuel pipe. The feed arrangement is therefore extremely simple, and as ample means for adjustment are provided, there is practically nothing to do after the first setting.

One of the interesting features of the carburetor is the double-disc baffle plate, in which a large number of holes are so drilled relatively as to be in no sense opposite each other. This results, it is stated, in a high degree of atomization of the fuel as it is drawn past the discs and onward into the induction pipe.

HOME MADE VALVE LIFTER.

The average workman has in his tool kit a valve lifter which he prizes, in that it is suitable for the majority of motors. Occasionally, however, it will be found that the regular tool will perform the work easily. A simple form of tool for compressing the valve springs is shown at Fig. 2 A. It is a common type, but as it is constructed easily it may be of service to some repairman who encounters a motor not adapted to the regular lifter. It will be noted that the fulcrum member is provided with a number of holes for adjusting the lever to varying heights of the cylinders. The retaining bolt is threaded at one end to take a wing nut. The material can usually be secured from the scrap heap.

PISTON RING CLAMP.

Replacing the cylinder over the piston is sometimes a difficult task, although simple enough when the operator has an assistant to compress the rings. An easily made clamp and one which will enable the workman to replace the cylinders without help, is depicted at Fig. 2 D and E. It is made of sheet metal, rolled to the form shown at D and provided with two wings or extensions to take a threaded bolt carrying a wing nut. The clamp is slipped over the piston and rings, and the nut screwed up, compressing the rings into place. The cylinder is then slid over the piston, and the tension of the clamp relieved. As the cylinder moves downward it will slide the clamp along. The piston and rings should be well lubricated before the clamp is affixed to prevent binding or injury.

RENEWING TEETH IN FIBRE WHEEL.

A driver who cares for his machine had the misfortune to have two teeth of a fibre timing gear strip through a small piece of metal getting between them when the engine was operating. Not wishing to lay the machine up while awaiting a new gear, a repair

was successfully made in the following manner:

A piece of square fibre slightly wider than the thickness of the wheel was secured and the latter sawed as shown at Fig. 2 B, the surface being smoothed up with a file. The block was then cut to make a driving fit after which a template was made from the good teeth, for marking off the required members on the insertion. These were cut with a hacksaw, smoothed and trued with a file, after which two circular brass plates were turned up and placed in position as shown at C. The plates were then secured by rivets.

MORGAN TOOL HOLDER.

A handy tool holder, combining as it does the functions of a number of similar devices, is the Morgan, manufactured by B. Morgan, Newport, R. I., and shown at Fig. 2 F. It is made in three sizes, constructed from hardened steel, carefully machined, and the tool post will hold securely round, flat, square, hexagon and shaped tools from the largest size to a No. 60 drill. The two machined parts are held together by a slotted link, keeping them parallel with respect to side motion, but allowing the two parts of the holder to swing around to a straight line and to reverse their position.

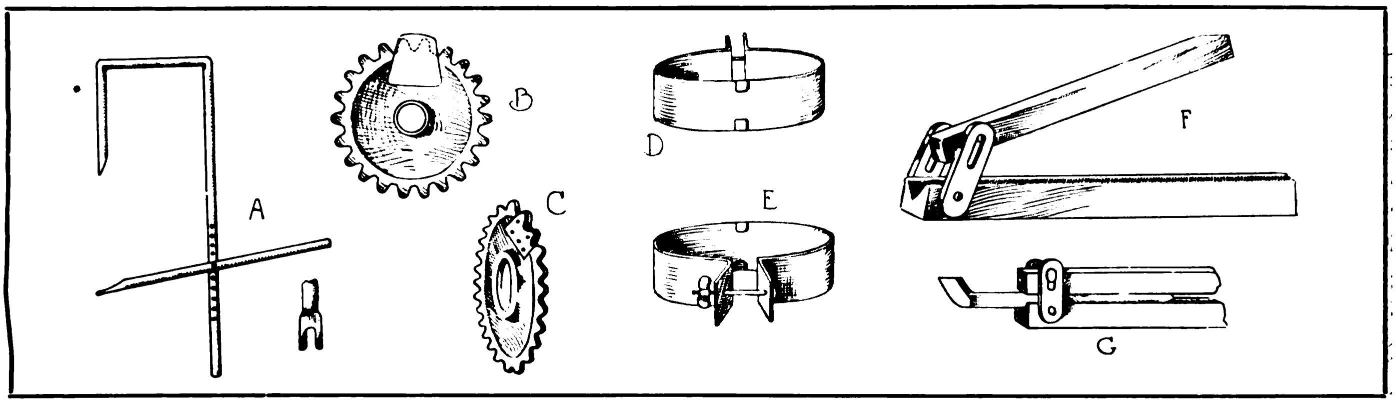

Fig. 2—Useful Tools for the Repair Shop: A, Easily Constructed Valve Lifter; B and C, Method of Replacing Broken Teeth in Fibre Gear; D and E, Piston Ring Holder; F, Morgan Tool Holder; G, Holding a Diamond Point Tool.

The heavy portion of the holder has a deep V slot on one side and a hair line on the opposite, while the smaller or lighter bar has a V slot on one side and is plain on the other. The V slot in the lighter portion registers with the deep V slot in the heavy section, which enables large tools to be held. When the tool is reversed the small or hair line slot has a plain or blank bar opposed to it, enabling the clamping of the lightest drills. A complete set of tools is manufactured, there being 11 in all, and the sizes vary according to the equipment. At G is shown the holder on the square and with a diamond point inserted.

LIGHTING THE WASHSTAND.

The very general adoption of the mechanical transport by florists, undertakers, department stores, etc., has resulted in a number of elaborate bodies which are nicely finished. This means that the garage or service station caring for these cars must provide excellent service in the matter of washing and polishing. A proprietor of a garage who caters to a nice clientele has devised the lighting panel shown at Fig. 3 and as a result the washer is not only sure of good illumination, but cannot make excuses for poor work.

The panel was constructed easily, the material being two smooth boards about five feet long, six or seven inches wide and .625-inch thick, although these dimensions may be altered to suit convenience of stock and location. The boards were joined as indicated at B. Lamp sockets were attached and wired and the interior of the panel given several coats of white enamel paint, which formed a good reflector.

Two panels were made, one for either side of the space occupied by the machine, and fitted with suitable rope and pulleys so that they could be raised and lowered as desired. Being adjustable the washer is able to have good light for the running gear as well as body.

At C is presented a suggestion for a light stand. It comprises an old music rack, having an adjustable rod to which is secured a reflector which could be of such size as to permit of the use of three or four lamps. The rack could be mounted upon a wooden base and with sufficient length of flexible cord and a connecting plug, the stand could be moved to any desired position. Such a device would prove of service when working on the chassis in the overhaul.

ALLEN FRICTION WRENCH SET.

A tool that presents interesting features which will appeal to the repairman as well as driver caring for his own machine, is the Allen friction socket wrench. It is not a ratchet tool and its grip is secured through a patented application of the friction principle. An instantaneous grip is secured without lost motion, making the device particularly adaptable for removing and replacing nuts or bolts where the space is very limited. The tool is practically a solid member when assembled and is reversible.

The maker lays great emphasis upon the high grade material and workmanship and the wrench is a drop forging of high point carbon steel, carefully machined, pack hardened and finished. All moving parts of the

friction member are ground accurately and the limit is exceedingly fine. Three sizes are manufactured, the No. 31 set being shown at Fig. 4. This comprises in addition to the wrench, 31 steel sockets varying by thirty-seconds from .3125 to 1.28125 inches. These are of high grade steel and each is heat treated and case hardened. Two extensions are provided, a short and long member, the latter being 9.5 inches, also a universal joint. This is constructed in a substantial manner and designed for hard service.

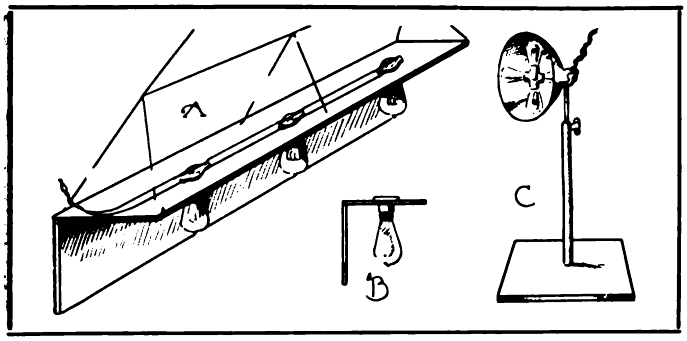

Fig. 3—Easily Constructed Lighting Devices for the Washstand: A, Panel and Method of Suspension; B, End View; C, Adjustable Stand Constructed from Music Rack.

There are also three square sockets, these being .40625, .53125, .65625 inch, respectively. A screw driver and spark plug wrench are included as well. The outfit comes in a neat box and is moderately priced. The maker, the Allen Wrench & Tool Company, 4 Meadow street, Providence, R. I., manufactures different sized outfits to meet individual requirements. A drill attachment is being produced by the company.

HEATING DUE TO CIRCULATION.

Heating of the motor may be due to a number of causes such as too rich a mixture, loose fan belt, retarded spark, timing, etc. An instance of an engine heating after an amateur overhaul was noted by the writer recently. The driver was puzzled to account for the trouble and although the pump appeared to work properly, the motor became hot after running a short time.

It developed that in the overhaul the operator had not given any attention other than fitting new gaskets to the water connections and admitted that he had not looked over the pump as it was working properly before the overhaul. Upon taking the member off the power plant it was found that it was fitted with a screen and that the meshes had become clogged with sediment. When cleaned and replaced the cylinders were normal even after running the motor for some time. In connection with this work the novice cannot be too careful to note that the openings of the gaskets correspond with those of the piping and cylinders when these members are in position.

PROPER HEAT FOR ANNEALING.

The proper temperature for annealing is almost a forging heat. Keep at a bright red long enough to overcome all strains which may have a tendency to manifest themselves during the hardening process. It is not good practise to use cast iron chips or turnings for packing, as they will decarbonize the steel to such an extent as to prevent successful hardening afterward. Packing parts too near the walls of the annealing box will have almost the same result as the chips; in fact, it will be worse, as the decarbonization will be unequal and the surfaces nearest the box sides will be affected, thus making uneven whatever hardening is possible.

Shops that have not the facilities to allow of using the above described annealing process, may obtain satisfactory results by heating the steel in a charcoal fire to about an even forging heat. Then put a few inches of the fire ash in a box and on top of the ash place a soft pine board, over which the heated work is laid and the box covered. The wood will char and smoulder and the steel will remain hot for a considerable period. A box of cold ashes may be utilized to accomplish the same results to a less extent, as the cold ashes and lime are apt to chill the steel. However, when either of the materials is used hot, good results will be obtained.

A SOLDERING TIP.

In working with soft solder and using rosin for flux to give a nice appearance, the melted rosin may be removed with a cloth moistened with benzole.

CUTTING SQUARE THREADS.

A lathe kink for cutting square threads is as follows: With an ordinary V shaped cutter, form a thread of the proper lead that will be equal in depth and width to the cut of the finished square. Then follow down with the regular square tool. This saves the latter, which cuts a square or broken chip. A roughing member should be used before cutting. If more than one piece is to be threaded, rough first and then finish, as this will keep the tool sharp and result in a nice finish. The rougher should be speeded up and allowed to dig out the metal without regard to finish.

Fig. 4—The Allen Friction Wrench Set, the Wrench Proper Operating on the Friction Principle.

CORRESPONDENCE WITH THE READER.

Acetylene for Starting.

(25)—Can a motor be started with acetylene gas from a generator? I read somewhere of a driver who claimed to have detached the tube from the lamps and led it to the air intake of the carburetor. Is it practical? M. W.
Garden City, N. Y., Jan. 15.

A motor may be started with acetylene when combined with proper proportions of air to make an explosive mixture. There are several motor starters on the market employing acetylene which is combined with air by a regulating valve or mixer. The writer has never seen a cold motor started in the manner mentioned, but has been informed that acetylene gas led to the intake manifold aids in starting.

Lead of Magneto.

(26)—Having converted a pleasure vehicle into a truck and secured a Bosch magneto with variable advance would be pleased to receive information as to installation. Do you install it the same as a timer and set it the same, or do you time it earlier? How do you figure out the advance in proportion to the size of motor? CONVERT.
Trenton, N. J., Jan. 5.

The drive, direction of rotation and speed are factors to be considered. The magneto must be driven in the same direction as marked on the instrument and this is determined by looking at the shaft end, that part of the shaft to which the gear or driving member is to be attached. Magnetos are driven either clockwise or anti-clockwise, usually in the former direction. When fitted to single, two and four-cylinder, four-cycle motors, the magneto must be driven at crankshaft speed.

The drive should be positive, by shaft or gears when possible as chain, unless of the silent type, enclosed and running in oil, does not give satisfactory service. An exposed chain will wear and affect the timing. Another factor to be considered in chain drive is the stress upon the armature bearings. If provision is not made for mounting a magneto, it is possible that the crankcase can be cut into and a gear drive secured. This will necessitate the making of a pattern to enclose the parts.

As to timing, the magneto is usually installed so that the contact points of the breaker box open at a certain point, corresponding to a predetermined angularity of the crank throw from vertical, the relation of the piston travel to the rotation of the crankshaft depending upon the stroke and the length of the connecting rod.

It is a simple matter to ascertain the piston travel in inches by inserting a wire or small rod through an open petcock. It is not so easy, however, to determine accurately the rotation of the crankshaft, and to obviate the necessity of lengthy computations the diagram presented at Fig. 5 was compiled by the Bosch Magneto Company, New York City. With this it is a simple matter to determine the angularity of the crank throw from vertical, provided the stroke and piston travel in inches are known.

In the diagram the relation between the piston travel and the connecting rod length is 1:4.5. The vertical lines numbered at the bottom give the stroke of the motor in inches, the rotation of the crankshaft in degrees being indicated by the slanting lines and the figures at the right. The figures on the left and the horizontal lines indicate the piston travel in inches.

To illustrate the use of the diagram: Let it be assumed that it is desired to find the piston travel for an advance of 30 degrees on a motor having a six-inch stroke. The vertical line for the desired stroke may be identified by the figures at the bottom of the diagram, and this vertical line is followed until it cuts the diagonal line indicating the desired number of degrees, which is 30 in the present case. The horizontal line nearest this point is followed to the left, and in the illustration it will be noted that it indicates about .5 inch. This figure denotes the advance in inches cor-

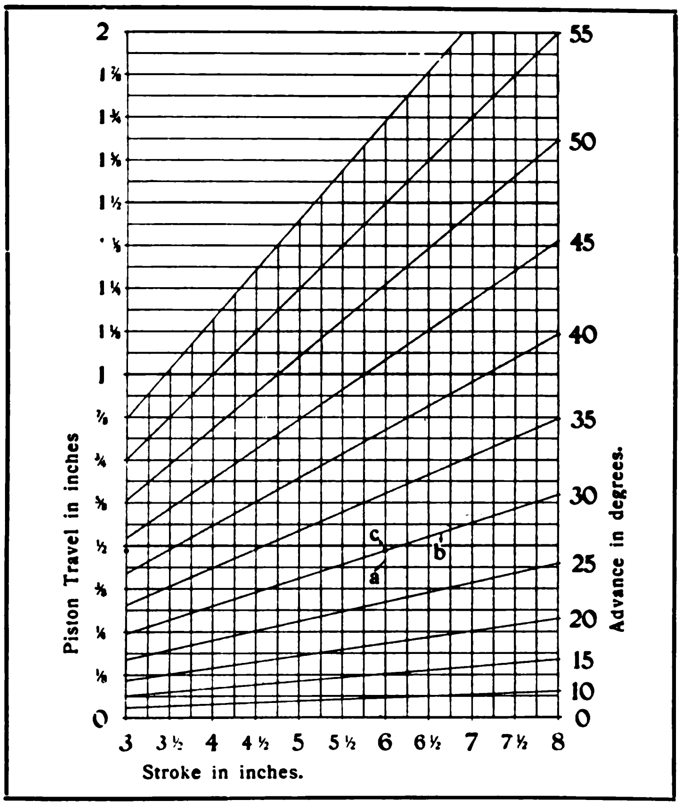

Fig. 5—Bosch Timing Diagram for Ascertaining the Angularity of the Crank Throw from Vertical When the Stroke and Piston Travel Are Known.

responding to a rotation of 30 degrees of the crankshaft.

Consequently in setting a magneto on an engine having a stroke of six inches, it will only be necessary to insert a wire in the opening of the petcock of the proper cylinder, the first, for example, and turn the flywheel backward past dead centre until the piston has descended about .5 inch. This will correspond approximately to a rotation of 30 degrees of the crankshaft.

The type of magneto was not mentioned, but in connecting the leads to the distributor, the firing order of the motor must be considered as when timing by the usual commutator. The Bosch Magneto Company, 225 West 46th street, New York City, will forward complete information upon request. The type of magneto should be mentioned in the communication.

FOREIGN TRUCK NOTES OF INTEREST

RUSSIA BUYS SAURERS.

Large Order to Be Filled by Switzerland Maker Includes Repair Shop on Wheels.

The Russian government has ordered 76 motor trucks for army use of the Arbon factory at Arbon, Switzerland, of which Hippolyt Saurer is the head. Among the types being furnished are a heavy ambulance, convertible or duplex truck, the body of which is so arranged that it could carry aeroplanes or seats as desired, and a series of vehicles to make up a new unit of warfare, called by the Russians an "escadrille," which also has intimate connection with aviation. This unit is made up of two touring cars, three material trucks and one "factory" truck.

Each of these machines tows a trailer of unusual length, upon which an aeroplane is carried, a total of 18 pieces for each of the units. "Indications are," says Mr. Saurer, who recently paid a visit to the United States, "that this new branch of the service is looked upon as a useful addition to the war strength of the army. The so-called factory truck is a veritable factory on wheels, having a complete machine shop, equipped for not only making minor repairs, but also to do heavy and major replacements and refittings.

INTERESTING SCOTCH PRODUCT.

Albion Trucks Utilize Gasoline or Kerosene Carburetor at Purchaser's Option.

One of the oldest concerns engaged in the production of commercial motor vehicles in Great Britain is the Albion Motor Car Company, Ltd., Scotstoun, Glasgow, Scotland. The Albion is made in three types of chassis, fitted with 15, 16 and 32 horsepower motors, respectively. That illustrated herewith is the largest.

The motor is a four-cylinder unit with bore of 4.5 inches and stroke of five. The inlet and exhaust valves are mechanically operated, and the camshaft and governor gear wheels are enclosed. Relief cams fitted to the camshafts are designed to make easy the reduction of the compression and the starting of the engine. Lubrication is by a patented system of force feed. Ignition is by high-tension magneto, driven through the Albion patented flexible coupling.

The clutch is a single disc type. The transmission gives three forward speeds and reverse. Forward speeds are operated by positive clutches, the gears always being in mesh, while the reverse is obtained by sliding gears. Two sets of brakes are fitted. Standard wheels are of cast steel, and for colonial work steel tires are fitted if desired.

Contractor's Tipping Body Installed on Three-Ton Albion Chassis for Use on Island of Trinidad.

The machine illustrated was constructed for a government contractor on the island of Trinidad, and for such countries the company supplies a kerosene carburetor upon option. The general principle upon which this vaporizer operates is that the fuel is fed by the usual type of float chamber to a jet and is atomized by the inrushing air. Only a small proportion of the air is taken over the jet, and the rich mixture of air and atomized kerosene is immediately conducted to a chamber having a very large corrugated heated surface, the heating being accomplished by the exhaust gases. The rich gas from this chamber is led to a double-beat mixing valve controlled by the governor, which in conjunction with the speed air valve is held to permit under all conditions of load and speed the correct amount of additional air to enter with the rich vapor to insure the most efficient and economical mixture reaching the engine. This matter of kerosene carburetion is meeting with general interest in cost of gasoline and the success of the Albion is such as to indicate its possibilties.

Several standard types of bodies are supplied by the Albion company, these being suited to the various requirements of the individual purchaser. The tipping body shown has met with decided favor. It is constructed to carry a load of three tons. The tipping mechanism is operated by the motor, a winding drum being fitted at slight extra expense if specified at the time the vehicle is ordered.

BELSIZE DELIVERY VAN.

Type of Light Weight Vehicle That Is Proving Very Popular in England.

An accompanying illustration shows one of the 1500-pound Belsize delivery vans delivered recently to the Leicester Co-Operative Society, Ltd., Leicester, England. The car is made by the Belsize Motors, Ltd., Manchester, England, and is proving decidedly popular with a number of merchants and others in Great Britain.

The motor is a four-cylinder, vertical unit of the L head type, with bore of 3.6875 inches and stroke of 4.75. Inlet and exhaust valves are interchangeable and are mechanically operated. Lubrication is automatic. Cooling is by thermo-syphon with large water manifolds. The radiator is of the honeycomb type, and cooling is further aided by a powerful fan. Ignition is by high-tension Bosch magneto.

The clutch is a cone member, metal to metal, and the transmission gives four forward speeds and reverse, high speed being direct. The service brake acts on drums on the rear wheels, while the emergency member is on the jackshaft. Both are of the internal expanding type, metal to metal, and double acting.

The frame is of pressed steel of deep section. The front axle is a section forging fitted with ball bearing hubs and pneumatic tires are utilized on the forward wheels. The rear axle is of the live axle type, and solid tires are fitted to the rear wheels. The equipment includes a full set of tools and provision is made for the carrying of one extra pneumatic shoe.

The standard body is an enclosed van type, although the details are worked out to meet the special requirements of the purchaser. Open bodies also may be had. The design is intended as a light, strong vehicle which shall be capable of carrying medium loads, from 1500 to 2000 pounds, and making quick runs. The use of both pneumatic and solid tires is considered a decided advantage in the matter of maintenance cost.

Belsize Light Delivery Van of 1500 Pounds Capacity Utilizing Pneumatic Tires on Front Wheels and Solids on Rear.

BRITISH ENGINEERS COMING.

Accept Invitation Extended by American Society and Programme Is Now Being Formulated.

The council of the Institution of Automobile Engineers, London, Eng., devoted the last meeting early in January to the reading of a paper on "The Training of an Automobile Engineer," which was prepared by four of the graduates of the London section. The council considers that the matter is of extreme importance and will lead to a keen discussion.

The preparation of the programme for the visit to the United States is progressing and members will probably leave London, May 17, returning about June 24. The American Society of Automobile Engineers has extended its invitation to include the members of the Society of Motor Manufacturers & Traders, Ltd., so that the delegation to America will be considerably augmented.

The itinerary prepared by the American engineers includes visits to nearly all the leading manufacturing centres of the industry, the speedway races at Indianapolis and a three days' trip on the Great Lakes in connection with the summer meeting of the Society of Automobile Engineers. For this purpose the largest vessel on the lakes has been chartered for the exclusive use of the party. The journey through the states will be made in special cars.

ADDITIONAL NEWS FROM ABROAD.

Plowing Contest in Russia—In connection with the automobile exhibition to be held at St. Petersburg in May, under the direction of the Imperial Russian Automobile Club, it has been decided to inaugurate a competition for motor plowing machines.

Ambulance for Bulgarian Army—The Daimler Motoren Gesellschaft of Unterturkheim, Germany, is reported from Berlin to have secured an order from the Bulgarian military authorities for a 20 horsepower motor ambulance.

British Maker Adopts Installment Plan—In order to encourage the use of motor tractors and assist the farmers who desire such service in the United Kingdom, the Ivel Agricultural Motors, Ltd., has made arrangements whereby it is prepared to supply its latest type of machines on terms by which payment can be extended over a year. By this system the price is fixed at 3 per cent. higher than the cash terms. The plan also is suggested by other makers to meet competition arising from the so-called American invasion.

Plans for New Zealand Show—A special feature of the industrial exhibition to be held at Auckland, New Zealand, in 1913-1914, will be the exhibit of all kinds of motor vehicles. The event will be opened Dec. 1, 1913, and will be closed about the end of February, 1914. The proposed building provides 120,000 square feet of space and this will be increased as required. This exhibition will doubtless be of decided importance to manufacturers of industrial motor vehicles as the interest in the mechanical transport is rapidly increasing in New Zealand.

Japan Orders Army Transports—Following the example of all the large European nations, Japan, through its war department, has ordered a number of motor trucks for army service and announces a subsidy system which will encourage the use of such vehicles by individuals and business houses, the same being available for army transport in case of war.

No Trucks at Scottish Show—At the last meeting of the Society of Motor Manufacturers & Traders of Scotland, Mr. Matthew reported that the proposed Scottish show of industrial motor vehicles had been abandoned and that no business vehicles would be shown at the next motor exhibition at Edinburgh.

Canadian Company Adopts Electrics—The Canadian Express Company is the first concern of its kind to operate motor trucks in Canada and recently put in service a fleet of electric vehicles in Montreal and Toronto. John Pullen, president of the company, states that the experiment is being tried to secure the highest efficiency in accordance with commercial economy. If the results hoped for can be obtained with the electrics the horses and large stables gradually will be eliminated. It is planned to use the electrics all the year round at Toronto, while in Montreal, where the severe northern winters offer less advantageous climatic conditions, it is expected they can be used at least seven months in the year. The express company is installing its own charging stations and this work will be done at night.

Germany's Postal Vehicles—According to the statistics of the German postal authorities the number of government owned and rented motor wagons used for mail service is 52, 39 of these being owned and 13 rented. This does not include the wagons used on 16 routes for both postal and private purposes. Of the 52 vehicles, 12 omnibuses, mostly of 10 seats, are used for transporting letters, parcels and persons; 25 wagons, resembling the ordinary express motor wagon, for letters and parcels only, and the others are small three and four-wheel machines used for collecting regular mail, special delivery, etc. The wagons are partly electric and partly gasoline. In consideration of the favorable results obtained with the electric vehicles, the government has ordered 25 more of this type. The question of superiority in postal transportation is now removed from the stage of experimentation and has been decided in favor of the power wagon.

Tractors Aid Canadian Farmers—It is stated that the difficulty of securing farm labor in Canada is directing more and more attention to the use of the motor tractor for farm work. The experience of the farmer is that it requires fewer men and less attention than horses. It is estimated that at the present there are in the three prairie provinces about 6500 motor tractors and notwithstanding a wet season each of these has made at least 60 days of work in breaking new sod. The average acreage ploughed daily by each tractor is placed at 10, which means that about 3,900,000 acres of new land has been broken for the 1913 crop.

British Parcel Post Service—An excellent motor parcel service is being developed at East Lancashire, England. A motor truck, said to be the largest up-todate parcels van in service, has been running recently to Preston and Chorley through St. Annes and Lytham and the service has been extended to Liverpool and Manchester. The Blackpool van leaves at 7:05 in the evening every day and travelling by the coast route to Preston and thence by way of Bolton and Bury, reaches Manchester soon after midnight. The return journey is begun about an hour later and Blackpool is reached again soon after 6 in the morning, ready to send out parcels by the first delivery. Parcels for Warrington and Liverpool are transferred to another van at Chorley. The Blackpool van covers 111 miles every night.

To Garage Mail Wagons—The big garage built at Toronto, Can., for the Imperial Motor Company has been sold to the Canadian government for $80,000 and is being used to house the royal mail cars. These cars handled the British Christmas mails with expedition. The six mail wagons are to be stored on the ground floor of the garage and another part of the building is used as a storeroom for postoffice supplies. A repair shop is located on the top floor.

New Traffic in Denmark—A decision was recently given by the Danish customs authorities to the effect that motor fire engines of all kinds imported into the country are to be classified under No. 167 of the tariff, the duty being 5 per cent. ad valorem.

THE A B C OF MOTOR TRUCK IGNITION.

Part VI—Outlining the Various Systems Utilized with the Commercial Gasoline Vehicle, Their Components and Application in Practise—Describing Function of Spark Plug and Method of Timing the Spark—Wiring Plans Discussed.

THERE are two methods of electrically igniting the mixture or gas in the cylinder, one of which employs a low-tension current or the make-and-break system, while in the other the induced or high-tension current jumps between the two points of the spark plug, which gap or space breaks the continuity of the secondary circuit. The former method comprises an igniter plate, mechanically operated, and this system will be taken up and described in its logical sequence.

The jump spark plug is a very simple device and there is, perhaps, no other component of the motor car which is represented by so many different makes. The principle of operation is similar with each and a general description of the device will serve. It consists of two terminal electrodes separated from each other at the points within the cylinder by an air space, and at other portions by means of suitable insulation.

Construction of Spark Plug.

By referring to Fig. 26, which depicts two conventional methods of construction, the arrangement of the various parts will be noted. It will be seen that one terminal or point is integral with the shell, which also is of metal. The other electrode runs vertically through an insulating material in the centre and this insulation may be porcelain, mica or some similar substance through which electricity cannot pass. The shell is threaded for screwing into the cylinder and when the plug is fitted the gap section extends into and comes in contact with the explosive vapor.

It has been explained that a path must be completed before electricity can flow and that the metal of the motor or frame provides one side of the circuit because one lead from the source of current is attached to the frame or other metal part. The shell of the plug being of metal and screwed into the cylinder makes it a part of the ground side of the circuit, or the return path as it may be termed for the purpose of explanation.

Operation of Plug.

In the previous installment it was shown that the high-tension current was led to the spark plug terminal by means of a very heavily insulated wiring. Assuming that the terminal of the cable from the coil, where the low-tension current has been converted into a high-tension, is attached to the terminal member on the top of the spark plug, the former being of metal and in contact with the metal electrode extending through the porcelain or insulated material, the current will flow until it reaches the air gap. At this point resistance is encountered, but if the vibrator of the coil be adjusted properly and the current be of sufficient strength, the electricity will jump across the gap to the other terminal in its effort to return by the way of the shell, cylinder, frame, etc., to the battery, thus completing its circuit.

Porcelain and mica are most commonly utilized, although stone and lava are employed for insulating material in high grade plugs. By referring once more to Fig. 26 it will be noted that A presents the porcelain design and B the mica. It will also be seen that the insulating material of the former is thickest in the centre and that the shoulders conform in shape to a recess in the shell. Between the porcelain and metal is inserted a copper and asbestos gasket which serves two purposes, one being to provide for the expansion of the porcelain and metal when heated and the other to prevent the escape of any of the compressed mixture or burnt gases.

In assembling the parts of the plug, the washer member rests against the shoulder of the shell and the

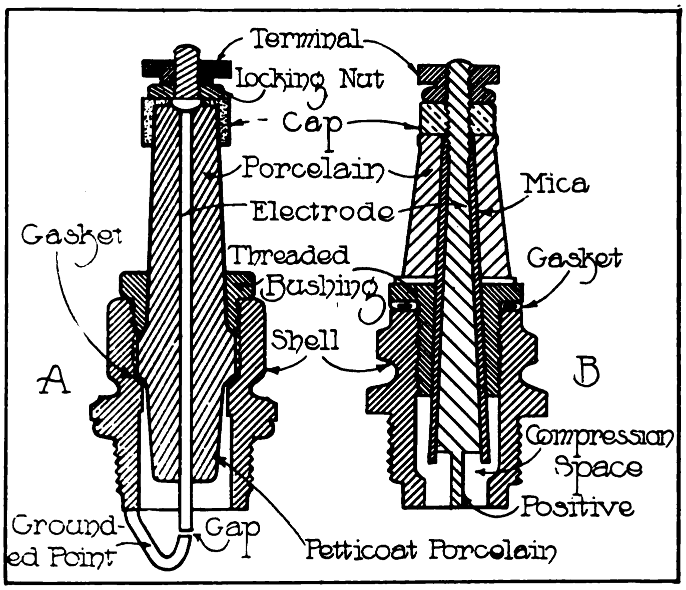

Fig. 26—Illustrating the Construction of and Components of Spark Plugs: A, Porcelain Type; B, Showing Insulating Material of Mica.

porcelain is held securely against it by a threaded bushing which when screwed down compresses the washer, making a perfectly gas tight joint. Copper and asbestos combinations are not always utilized. The washer may be asbestos or other similar suitable material.

It is important that the metal vertical electrode be fitted properly so as not to permit of the passage of gas, etc., and usually the top of the porcelain is protected by a metal cap which is retained by a nut. Another terminal member is fitted for the purpose of securing the terminal of the secondary wire.

Mica Spark Plugs.

At B is shown a conventional construction of a mica plug. In this particular type the electrode is sur-

rounded by a high grade of mica and two layers of the material are usually employed. Over the mica is placed a porcelain shell. As previously explained the insulating material may be of lava, stone, etc., and although many plugs are so designed that they may be disassembled for cleaning purposes, some makers utilize a construction in which the insulation is practically integral with the shell. With this form it is held that there is no possible opportunity for leakage.

That there is a wide divergence of opinion among manufacturers of spark plugs will be noted by the types presented at Fig. *27*. Both ordinary spark plugs, so-called because they are adapted more especially to the chemical source of current, and the magneto type are shown. With the latter not only are the points set closer together, but they are of special alloys to resist the burning tendency of the spark produced by the magneto. It is obvious that in time the action of the current burns the surface away slightly and manufacturers of magnetos as a rule advise the use of magneto plugs because of this burning action. While the ordinary plug may give good service for a certain length of time when employed with the magneto, provided the gaps are correct, the writer holds that much of the supposed faulty action of the mechanical generator is due to the irregularity of the gaps on the ordinary plugs.

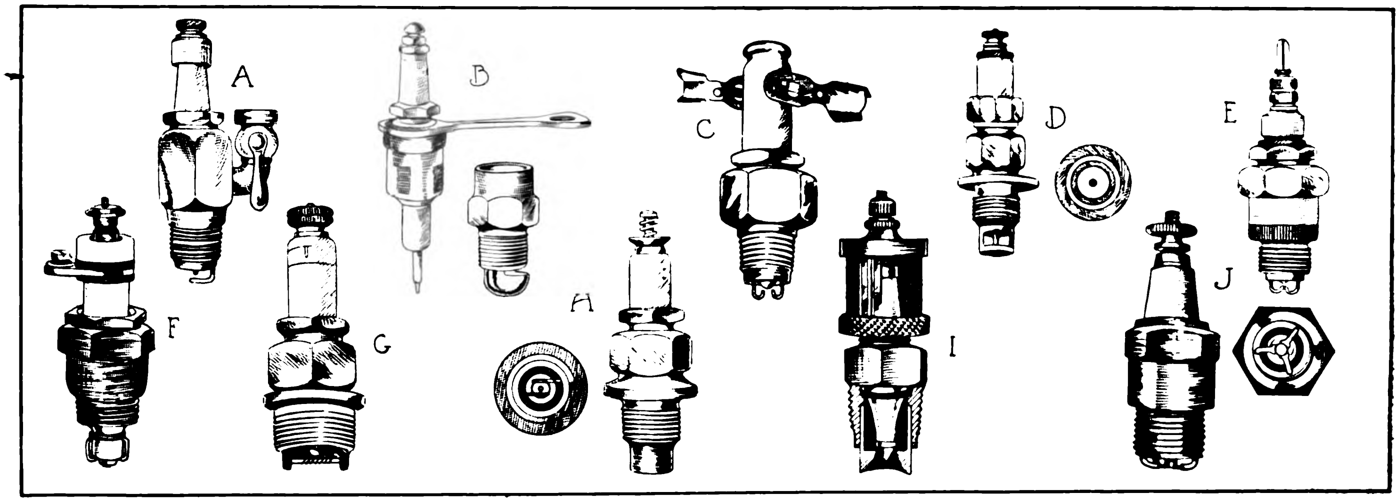

Fig. 27—Illustrating Conventional Types of Spark Plugs: A, All-in-One; B, Mosler Breech Block; C, Edison Double Plug; D, Mosler Spit Fire; E, Hartford; F, Lodge Double-Pole; G, Eisemann Magneto; H, Black Eagle; I, McCormick; J, Bosch Magneto.

A single gap is not always employed and there are a number of plugs marketed which have a multiplicity of terminals on the shell member. One of these is the Bosch, made by the Bosch Magneto Company, New York City, and shown at Fig. *27*. It will be noted that three electrodes having a knife shaped edge are integral with the shell and extend toward and into proximity to the central or main electrode. It is held of this construction that the spark does not jump but rather forms a ribbon of flame between the electrodes, making for greater efficiency and easier starting of the motor. Another quality of the design is that in the event of one point becoming sooted or creating too much resistance another member will provide the proper path. This make of plug is free from nuts or washers and the insulating material is fitted by a special process.

Magneto Plugs.

A type differing from the Bosch is the Eisemann, made by the Eisemann Magneto Company, New York City, and specially adapted for magneto work. It will be noted that a metal bar is integral with the shell and carries a spiral wire. That the central electrode is not always exposed is illustrated by the Mosler plug, made by A. R. Mosler & Co., Mt. Vernon, N. Y. Here the extension of the shell prevents oil from reaching the interior of the plug, the flame being projected into the cylinder through a small opening in proximity to which is the terminal of the central electrode. The sides of the extension part have suitable openings and it is held that the construction keeps cool the parts exposed to the heat of combustion. Owing to the liberal size of the electrodes it is claimed that the plug will operate equally well on the battery or magneto.

Some plugs are so constructed that the central insulated member may be removed easily by a slight turn of a handle and this type is known as the breech block plug. That shown at Fig. *27* is a Mosler and the end of the shell is spherical, protecting the sparking points from the action of oil, soot and heat. By moving the handle slightly, the central member may be displaced for inspection or other purposes.

In addition to the types illustrated, which include petticoat, conical and closed end, there are plugs which have a priming attachment. One of this construction is the All-in-One, made by the Frontier Specialty Company, Buffalo, N. Y., and shown at Fig. *27*. This comprises a petcock screwed into the shell and having a passage registering with the opening of the plug proper. This is designed for motors not equipped with priming cocks and where the plug must be removed when the cylinders are to be primed with gasoline for starting.

Double Pole Plugs.

The advantage of two point ignition is well recognized by engineers as with two sparks in the cylinder greater power and efficiency are derived, without util-

izing a double distributor magneto or double the number of wires. In the Lodge spark plug, marketed by Marburg Bros., New York City, two concentric electrodes are employed at the base of the core, both well insulated from each other and from the ground. This construction differs from those previously described in that there is no connection with the ground or between either of the electrodes.

All that is required is to have two spark plug openings for each cylinder and to connect the magneto and two plugs in such manner that one electrode of a double-pole plug is connected to the magneto and the other electrode of this double-pole plug to the insulated electrode of an ordinary plug. The current from the magneto will thus pass through both plugs in series and fire both at the same time.

Another type is the Edison double system plug designed for providing a dual system of ignition where the cylinder has but one spark plug opening. As will be noted by the illustration, two terminals are provided, one on either side, and the current from the battery, for example, is led through the secondary wire to one terminal. That from the magneto is secured to the other member. This permits of using either source of current independently of the other.

No attempt has been made to describe all the various types of spark plugs manufactured; rather to give a general description of spark plug construction and application. The adjustment of the gaps, cleaning, proper location, troubles and remedies will be taken up and discussed in logical sequence.

Having shown the method of converting the low-tension current into a high-tension by means of the induction coil and leading it to the gap of the spark plug, the timing of the flame will be considered. It was explained that the spark is supposed to take place at the completion of the compression stroke and that the timer is advanced in proportion to the speed of the piston to offset the time lost by converting the current from primary into secondary.

Timing the spark is a simple matter and is accomplished by varying the position of the rotating roller or brush member of the timer; that is, so securing it to the revolving shaft that contact will be made and the primary circuit established when the piston is approximately at top dead centre of the compression stroke.

There are several ways of timing the spark or setting the commutator and at Fig. 28 is shown the operation. The motor is cranked until the inlet valve of the first cylinder to be fired (that nearest the radiator when the power plant is a four-cylinder unit) opens and closes, and the piston has begun its upward or compression stroke. This may be determined readily by opening all of the petcocks except the No. 1 and when this is compressing that fact will be noted easily by the resistance.

Locating Position of Piston.

Having started the piston on the compression stroke, open the petcock and insert a wire or a small rod through the aperture. Next turn the flywheel by cranking until the rod raises and continue the rotation until the rod stops. By rocking the flywheel back and forth the exact dead centre can be determined without difficulty. With a file cut a nick in the rod flush with the top of the petcock. The mark will indicate the dead centre position. This is shown by the dotted lines in the drawing and that at A indicates that the piston is moving upward and lacks about half an inch of completing the movement. The correct distance may be secured by measuring off half

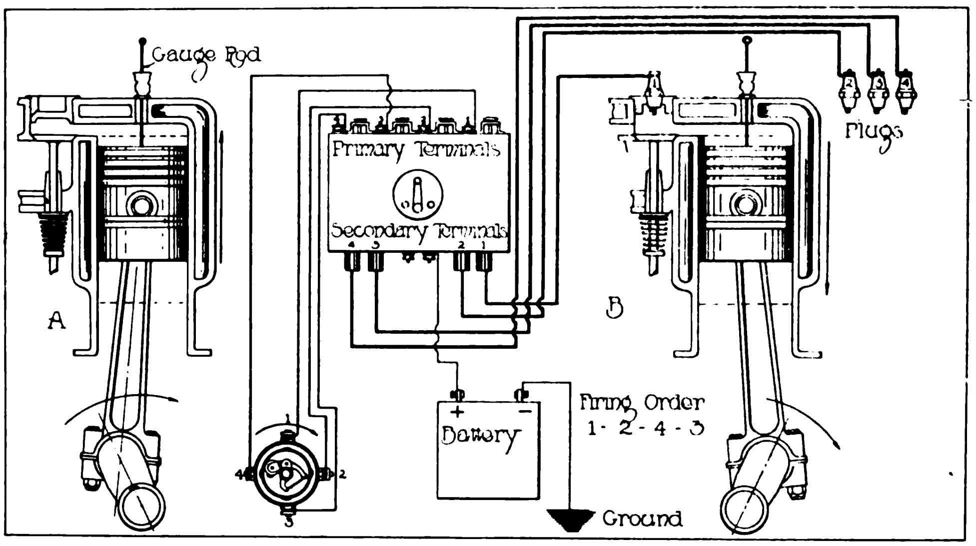

Fig. 28—Depicting Two Methods of Timing the Spark: A, Locating Position of Piston by Rod Inserted Through Petcock Opening, the Dotted Lines Representing Dead Centre; B, Timing of Spark with Timer in Fully Retarded Position and Wiring Plan with Motor Firing 1, 2, 4, 3.

an inch on the rod, above the original mark, and moving the flywheel backward or in an opposite direction to which it travels, until the second mark is flush with the top of the priming cup.

The roller member of the timer is then moved until the block makes contact with a terminal block and with the timer advanced to its maximum. The set screw or nut is then secured, locking the lever member in position.

While this is favored by some repairmen, the writer holds that the method shown at B has advantages in that there is no possibility of the novice making an error and inviting an accident through a back fire or carelesss operation of the spark lever in starting the motor.

The rod is utilized as before, but care must be taken to make sure that the piston is moving downward on the firing stroke. This is determined by in-

serting the rod and rotating the flywheel until the indicating member begins to descend. Continue the movement until the piston has descended about .5 inch, then set the roller member with the timer fully retarded.

By timing the spark in this manner there is no danger of the operator receiving a back kick with the starting handle, provided the spark lever is retarded. As he becomes familiar with the operation of the motor it is possible to advance the lever slightly for starting in cold weather, for example. In the event of play in the connections, should the timer advance slightly when the motor is stopped, the driver would not be as apt to be injured as with the other form of timing.

Wiring the Timer.

After setting the timer the next step is to connect the primary wires from the timer to the battery. The firing order of the motor must be known and this may be determined by watching the movement of the inlet valves. With four-cylinder motors the order will be either 1, 2, 4, 3 or 1, 3, 4, 2.

Assuming that the former is employed, the wire from the No. 1 terminal of the primary is connected to the primary post of the first unit of the coil. The second cylinder fires next and with the roller rotating in a clockwise direction the next contact to be made will be the second. This is connected with the second coil unit. As the firing order is 1, 2, 4, 3, it is obvious that the fourth cylinder fires before the third. In the natural course of rotation the next contact made in the timer is the third, so the wire from this post is carried to the fourth coil unit, since the fourth cylinder fires next in order and not the third as it would appear. The remaining post on the timer will be the fourth and this is connected with the primary member on the third coil as the third cylinder is the last to explode.

The attachment of the secondary wires is similar. As will be seen in the drawing the first and second cables, denoted by heavy black lines, lead to the first and second spark plugs, respectively. The third and fourth leads are then attached and in firing order. A little study of the wiring plan will enable the reader to understand the method of properly connecting the leads and it will be noted that the third and fourth contacts to be made by the roller are those of the fourth and third cylinder, respectively, when the firing is 1, 2, 4, 3. When the motor fires 1, 3, 4, 2, the primary and secondary wires must be attached to the cylinders in that order.

(To Be Continued.)

Ed. Note—The next installment will deal with high-tension distributors and various forms of igniters.

The Standard Glass Company, Chicago, has used a Buick commercial car, made by the Buick Motor Company, Flint, Mich., in its service for over a year and W. L. Eaton, general manager, states that the efficiency of the vehicle in carrying glass through the streets has been such that his company will completely motorize its equipment.

INAUGURATES SERVICE POLICY.

Grand Rapids Motor Truck Company to Assist Purchasers in Realizing Efficiency.

The Grand Rapids Motor Truck Company, Grand Rapids, Mich., has inaugurated a service department for the benefit of the users of "Decatur" trucks, and the purpose of the engineers of this department is to systematically assist those owning these vehicles in maintaining them, as well as to study and investigate the services with a view of securing the fullest measure of economy and productiveness. The department engineers are instructed to thoroughly tutor those having charge of the vehicles and then to supervise the work of the men and machines at frequent and regular intervals. The belief is that this department will bring about a decidedly increased efficiency and correspondingly minimize the expense.

GRAMM TRUCKS ABROAD.

Meeting with Decided Success in Philippine Islands and Under Similar Conditions Elsewhere.

Gramm trucks, made by the Gramm Motor Truck Company, Lima, O., are enjoying much popularity abroad. One firm at Manila, P. I., is using 25 of these vehicles and ordering others at the rate of about two a month. Honolulu is well supplied, several firms there using the Gramm to replace their horse and wagon delivery systems. Other countries using these machines are Brazil, Venezuela, Cuba, Porto Rico, Australia and New Zealand.

In some of the South American countries where steam and electric railroads have not penetrated and interurban transportation is proving a serious problem, the motor truck fills a long felt need. The Gramm company recently shipped a two-ton vehicle, equipped as a 20-passenger omnibus, to Brazil, where a firm of Americans has undertaken to establish a transportation service.

CO-OPERATION OF EMPLOYEES.

San Francisco Haulage Company Promotes Good Fellowship in an Interesting Manner.

The Emmons Safe Moving & Draying Company, San Francisco, Cal., each year tenders a dinner to its employees, at which it is customary for the workers to meet on a common footing and to consider subjects that are of interest to all and to develop a spirit of co-operation that is beneficial to the business of the company and promotive of the welfare of the workers.

This company two years ago began the use of Federal one-ton wagons and it now has four in service, with the probability of increasing this number materially. Through the wagons the company has decidedly developed its business.

LARGE TRUCK FOR MINE WORK.

California Concern Produces Vehicle of Special Design Fitted with Patented Dumping Feature.

The F. L. Moore Motor Truck Company, Los Angeles, Cal., has completed a Moore truck for the Kay Copper Company of Phoenix, Ariz., which is said to be the largest of its kind ever constructed. It is of special design and will be used for hauling copper ore from the mines to the smelter.

The truck has a four-cylinder engine, with large bore and long stroke, rated at 100 horsepower. The frame of the vehicle is made of steel girder heavily reinforced. It has a special patented power pump attachment which will dump the load in nine seconds, this being operated and controlled by the driver from the seat. The front wheels are 42 inches in diameter with wooden tires six inches thick and 13 inches wide. The total weight of the truck unloaded is 11,480 pounds. It may be loaded to seven or eight tons capacity and will pull trailers of similar capacity.

MACY'S THIRD REPEAT ORDER.

Fifteen Chase Delivery Wagons Replace 60 Horses in Service of New York Department Store.

R. H. Macy & Co., the well known New York City department store, has taken delivery of 15 additional Chase motor delivery wagons of 3000 pounds capacity each, made by the Chase Motor Truck Company, Syracuse, N. Y. They are stationed at the company's stable at Woodlawn, the Bronx, where they have displaced about 60 horses.

These vehicles are making daily deliveries over a wide territory, including the upper Bronx, practically all of Westchester county and nearby Connecticut. The Macy company has been using Chase trucks for 2.5 years and the last purchase is a third repeat order.

EFFICIENT MOTOR STAGE.

Reconstructed Locomobile Makes Daily Mileage of 90 with Very Satisfactory Results.

A Locomobile motor stage, placed in service about six months ago between Sacramento and Folsom, Cal., by the A. Meister & Sons Company of the former city, is unique in appearance, comfortable in appointments and very efficient in the duties it is called upon to perform. Supplying the motive power for the rear construction and stage body, both of which were designed by the Meister company, is a 1906 Locomobile 30 horsepower model H chassis, made by the Locomobile Company of America, Bridgeport, Conn., that had been driven over 120,000 miles before being adapted to its present service.

The rear or coach portion of the stage is very roomy, providing seating capacity for 24 persons as well as a large compartment for baggage and express purposes. The body pivots on a king bolt, which is fastened to the chassis and turns on a transom plate at the side. This stage, known as the Sacramento-Folsom air line, is in daily use between the two cities, making two trips, or about 90 miles a day at an average speed of 20 miles an hour. The total weight of the conveyance is 6000 pounds and the extreme length is 24 feet.

TESTING NEW POPE-HARTFORD.

Makes Run from Hartford to Boston Loaded to Rated Capacity Over Muddy Roads.

The first of the 1913 Pope-Hartford three-ton trucks, made by the Pope Manufacturing Company, Hartford, Conn., was recently delivered to the Boston service station of the company, making the journey from Hartford loaded with three tons of supplies. The vehicle left Hartford at 4 in the morning and arrived at Boston at 4:25 in the afternoon, making stops at Springfield and Worcester.

At the end of the run F. J. Glaser, who had charge of the trip, reported that the entire 130 miles was made on high gear and although the roads were muddy and slippery no adjustments of any kind were made. The gasoline consumption was approximately 6.5 miles to the gallon.

SUCCESS WITH KISSELKARS.

Chassis Fitted as Omnibuses Operating at Satisfactory Profit in Various Sections.

There seems little doubt that a man who can estimate transportation requirements and locate accordingly, can find in nearly any part of the country a fertile field for the motor 'bus. KisselKar 'buses, made by the Kissel Motor Car Company, Hartford, Wis., are in use in all parts of the United States and reports indicate that in every case the owners are operating at a profit.

A KisselKar line from Newburg to Cornwall, N. Y., paid so handsomely that the owner has added a second line from Port Chester to White Plains with equal success. Other recent instances of profitable operation of 'buses are cited at Chicago, Minneapolis, Providence, Detroit, Joliet, Ill.; Albany, N. Y.; Clarksburg, W. Va.; Highland Park, Ill., and Lynn, Mass. Many of these lines purchased the chassis only of the Kissel company, having bodies built and mounted in their own cities and according to their special ideas and requirements.

At the annual meeting of Adams Bros. Company, Findlay, O., maker of Adams trucks, these officers were elected: President, Joseph J. Kwis; vice president, C. H. Bigelow; secretary and sales manager, L. J. Adams; treasurer, B. B. Bigelow; general manager, W. D. McCaughey; purchasing agent, D. B. Adams.

New Commercial Car Accessories

Dean Regulite.

The Dean Regulite, marketed by the Waite Auto Supply mpany, Providence, R. I., is an electrical device designed for :achment to model T Ford automobiles when the generator utilized as a source of current for electric headlights. With is type of mechanical generator, the voltage varies in prortion to the speed of the motor and if the bulbs are not of oper size, at high car speeds the filaments are likely to beme destroyed. The Dean device regulates the pressure of e current, its principle being that of inserting resistance in e circuit automatically, and the maker holds that the lamps ill give a steady light irrespective of motor speeds. Excesvely high voltages are also prevented. The switch member is four steps or contacts to enable the adaptation of the sysms to generators of varying output of current. A feature the Dean is that the lamps may be dimmed if desired. It neatly constructed and takes the place of the usual lighting vitch on the dash. It is moderately priced.

Rayfield Strainer Trap.

The Rayfield strainer trap is produced by the Findeisen & ropf Manufacturing Company, Chicago, maker of the Rayfield irburetor. The device is designed for installation between ie supply tank and the vaporizer and is an important member the carburetion system in that it not only separates water id foreign elements from the gasoline, but prevents them aching the vaporizer and creating trouble. The fluid enters one end, flows directly to the bottom of the trap, and in risg to pass out, passes through a very fine metal screen. All cumulations are left in the bottom and may be removed by ieans of a petcock. A brace is part of the equipment and is esigned for attaching to any convenient frame or other car iember. The strainer is five inches high and 2.5 wide, and is onstructed to take .25, .3125 or .375 inch outside diameter tubig. It is constructed of brass, is nicely finished and is modrately priced.

Lubro Anti-Freeze Fluid.

Lubro Anti-Freeze Fluid, manufactured by the Lubro Oil ompany, 116 Prospect street, Cleveland, O., differs from the sual prepared solutions in that it does not require testing rom time to time to note if the freezing point has raised. It s a red fluid and the maker points out that there is no danger f the garage attendant emptying the cooler by mistake. One f the qualities of the fluid is that it does not boil or evaporate s readily as water and that it is especially adapted to moors which have a tendency to heat with alcohol solutions. The olor aids in locating tiny leaks in the circulating system and is also stated that it acts as a lubricant to the pump. It is eld that it prevents corrosion, thereby keeping the radiator lean. The company furnishes free of charge a preparation which will remedy leaks, when Lubro is purchased. One gal- on added to 3.5 gallons of water provides sufficient fluid for an rdinary radiator.

Hagstrom Priming Cup.

The Hagstrom priming cup, marketed by the Hagstrom ros. Manufacturing Company, Lindsborg, Kan., has been improved by the addition of a needle like member which may be adjusted to enrich the mixture if desired for starting purposes. The device is designed for attachment to the intake pipe or manifold between the carburetor and the cylinders and is utilized for priming purposes, in that the gasoline is inserted through a ball check opening at the top. When the motor is cranked the suction of the piston draws in a rich mixture and the fuel is vaporized by the attachment. The engine may be run with the rich mixture until the cylinders become warm. Features of the cup are that there are no levers to loosen or open and that the needle valve member may be closed or opened as desired.

Dover Saval Funnel.

The Dover Saval funnel, produced by the Dover Stamping & Manufacturing Company, Cambridge, Mass., makes for economy and ease in the handling of gasoline and is adapted for both the garage and private owner. Spilling of the fuel is prevented when filling the tank as the flow is automatically cut off when the funnel is lifted from the filling hole of the tank. This makes for safety in addition to economy. The funnel is provided with a large hoop on the base which rests firmly on the bottom of the tank, eliminating the possibility of tipping. The hoop is equipped with apertures, venting the spout and preventing it from becoming air bound. This and the ample size of the spout allow the contents of the funnel to be emptied in a very short time. A new, special extra hoop extends the entire depth of the funnel, and serves to retain the chamois. The Saval funnel comes complete with chamois and is designed to withstand severe service.

Apco Ford Cover Hood.

A device for protecting the cooling system against freezing temperatures has been brought out by the Auto Parts Company, Providence, R. I. It is designed for model T Ford automobiles, is constructed of rubber cloth, nicely stitched, and completely envelopes the hood and radiator. The device is padded with felt, and has an adjustable curtain permitting of closing the front of the cooler or exposing it as desired and according to the temperature. The hood is permanently secured and not only protects the water from the cold, but makes for easy starting, in that it keeps the heated water warm for a considerable length of time. It is easily attached and moderately priced.

McCormick Power Plug.

The McCormick power plug produced by the McCormick Manufacturing Company, Dayton, O., presents interesting features in that a large number of high frequency sparks are produced and they are constantly moving around the terminals. The sparks take place in a sparking chamber having a single restricted opening. During compression the gas is segregated in this space and when exploded a flame is projected into the cylinder. The spark gap is circular in form and all points are held to be charged with the same potential. When the gap is broken down, that is, when the discharge takes place, all points discharge simultaneously, producing a shower of sparks. Greater motor efficiency is claimed.

Devoted to Motor Driven Business Vehicles of All Classes.

VOL. IV. PAWTUCKET, R. I., MARCH, 1913 No. 3

STRIKE PROVES MOTOR TRUCK ECONOMY.

Enforced Demonstration of the Practical Utility of Machines, Without Efficient Loading and Unloading Equipment and Facilities, to Coal, Lumber and Building Materials Trade at Pawtucket, R. I., Means Abandoning Horses.

Harnesses FOR SALE Carts	50 Horses FOR SALE Apply Within

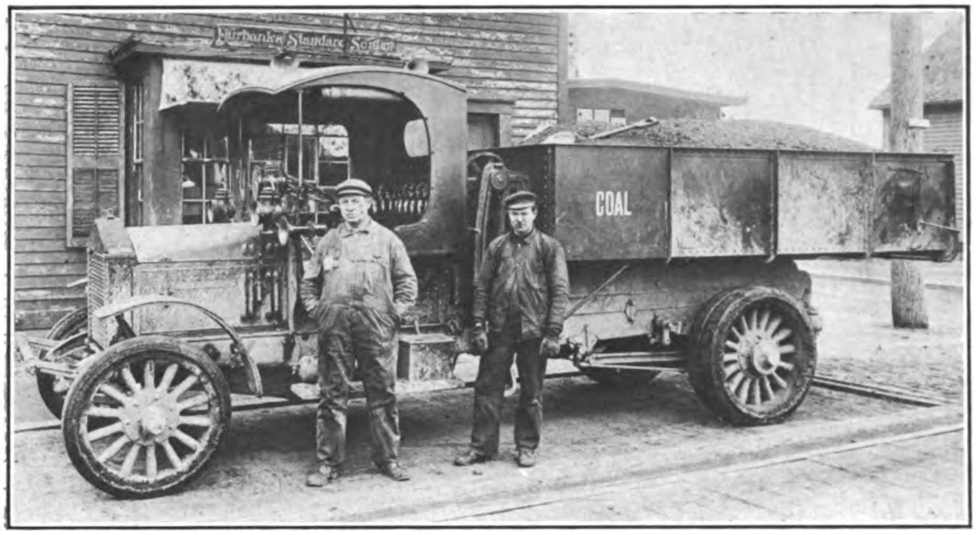
THESE two signs were placed in the office window of Olney & Payne Bros., Pawtucket, R. I., at the end of the first week of the strike of the Team Drivers' Union, and they were not removed when at the end of the second week the strikers abandoned their organization and individually sought to regain their employment. This concern is one of six engaged in coal, lumber and building materials trade in Pawtucket that refused to grant the demand of the drivers' union for an increased scale of wages, and it was the first of these to make public its purpose to motorize its delivery service as rapidly as it was possible to do this.

Weighing a Pierce-Arrow Truck and Its Crew at Olney & Payne Bros.' Office Before Going to the Yard for a Load of Coal.

For the first time probably in America motor trucks were utilized in an emergency of this character, and not only was business continued so that there was not material delay, but the practical demonstrations were such as to convince all of the firms that machines are in every way economical. While it was an enforced experience, representatives of the firms are unanimous in the opinion that they never would have had the practical knowledge gained because of the strike, and they all realize that there will be material saving for them to motorize their services. Some of them do not hesitate to say that the change must come quickly, for they understand the saving that can be made, and while it will undoubtedly mean a considerable expense in addition to the purchase of the trucks, there is no doubt of the purpose of the companies to dispose of their horse equipment as quickly as this may be done without sacrifice.

The six firms used about 300 horses and of the companies but one had seriously considered the use of trucks until the drivers made demand for increase of pay. Olney & Payne Bros. had last September taken delivery of a five-ton Pierce-Arrow truck; and another truck of the same size and make was received the morning the strike was begun. If the other firms had discussed the use of machines there was no serious thought of purchasing, because each man interested regarded the problem as one of very large proportions, and while it was generally believed the trucks were economical on long hauls, there was a firmly seated conviction that they would not show results as satisfactory as the horses when making deliveries to family trade.

But the strike made the use of trucks absolutely necessary, and they were worked under conditions that were decidedly adverse to maximum productiveness. This fact was understood and has been considered, and without exception every firm is agreed that the



Weighing a Pierce-Arrow Truck Loaded with Soft Coal Before Sending It Out for a Delivery Trip.

lumber and anthracite coal. It was using about 35 horses when the drivers went out on strike.

The City Coal Company, which deals in coal, wood, hay and grain, is the next in size and uses about 25 animals, and the H. R. McDuff Estate, dealer in lumber, has about 12 horses in its service. The total number of animals does not represent the entire equipment used for horses and wagons were at times hired temporarily.

The distribution by these companies, aside from the H. R. McDuff Estate, is from yards located at either side of the Blackstone river, and generally the haulage is about the same, which would indicate a nearer approach to uniformity of service than is usually the case in a community. The hauls, of course, vary materially with patronage, but aside from the grades from the wharves and coal pockets the conditions are such that at least average work can be done with the animals.

The companies have for a number of years had agreements with the drivers' union and with the expiration of the specified periods these have been renewed. In this instance the employers rejected the demands of the men and a strike followed in which every union man participated. While the negotiations were pending the employers learned what men they might depend on in the event of a strike, and ascertained that they might hire from manufacturers' agents and dealers a number of motor trucks. It was not until the morning the men refused to work that the companies knew the conditions they had to meet, and when it

possibilities with trucks are very large. Not only this, but there has been well established in the mind of every member of an interested company that it will be decided economy to make the investment required by the change from horse equipment, although it will be large in each instance.

The six companies transact business in an area extending north in the Blackstone valley a distance of about 15 miles, and into the town of East Providence and the towns of Seekonk, Attleboro and North Attleboro in Massachusetts. Pawtucket is the head of navigation of the Blackstone river and is the distributing point for this territory for fuel and building materials. Of these Olney & Payne Bros. is the largest in point of delivery equipment and does a large business as a contractor for supplying bituminous coal for mills and manufactories, handling for one concern alone more than 30,000 tons a year. Besides this it deals in anthracite coal at retail, and in brick, lime and cement in large quantities.

Next in size is the Newell Coal & Lumber Company, which has a large number of anthracite coal contracts as well as an extensive retail business, and handles lumber, brick, cement and lime. This company was using upwards of 60 horses at the time of the strike. The third concern in point of animals owned is the McDuff Coal & Lumber Company, with 55 animals in daily use, and this firm deals in coal, lumber and builders' materials. The fourth in size according to delivery equipment is the John T. Cottrell Company, which manufactures lumber as well as having a large trade in unfinished

was necessary for members of the firms in some instances to drive their own carts and to secure the aid of every man who could be spared from office forces to drive, the wires were kept busy to reach those who sold and used trucks.

Perhaps one of the reasons why the trucks were depended upon to a greater extent than might have been the case was that last September Olney & Payne Bros. began the use of a five-ton Pierce-Arrow machine, and this had been in constant service from that time. There was no knowledge, however, of what might be done with the haulage of lumber and building materials. With the declaration of the strike a member of the firm started in to drive this truck, for the driver had struck with the other union men, and the noon of the first day of the strike a second Pierce-Arrow truck, which had been ordered a month or more previous, was unloaded from a car. This gave the firm the second machine, and another member of the company started work with it that same afternoon. With the big contracts for soft coal there could be no cessation of the haulage between the yard and the works.

Meantime the Newell Coal & Lumber Company, the John T. Cottrell Company and the McDuff Coal & Lumber Company had arranged for the temporary use of several machines. It was found some of the agents for trucks in Providence were willing to let trucks for haulage for limited or unlimited periods, and owners of machines engaged in haulage not working on contracts were also willing to undertake the work. A number of Boston agents were communicated with and some were willing to have the companies use their trucks for indefinite periods. While it required quick action to gather a sufficient number of machines to meet the most urgent demands, before the end of the first day the companies had arranged for the use of about 20 trucks.

With horse equipment available the companies did not want to make plans for more than a day or two at the most for truck delivery, but a means had been found for continuing the deliveries and not one concern was seriously crippled, though with men not familiar with the city and not experienced there was not the same work done that would have been accomplished under normal conditions. It was necessary for the first few days to have a sufficient number of machines to take care of the work that was imperative, and delivery that was not absolutely necessary was left for the horse vehicles, for each company had found it possible to keep some of the animals at work.

The City Coal Company did not hire trucks, nor did the H. R. McDuff Estate, for with the former it was possible to keep up with the urgent demands with the drivers recruited from the yard and office forces, and with the latter the business in lumber was probably at the lowest point of the year. In fact the coal trade was the greater part of the delivery by all, for winter patronage is either from those who have use for coal constantly and have small storage facilities, or

The Soft Coal Loading Machine and a Truck with a Body from Which a Load Must Be Shovelled; a Combination but Partly Advantageous.

White Truck with Power Dumping Body Filled with Anthracite Coal by Shovellers; a Decided Loss of Time Through Lack of Yard Facilities.

could be obtained, conditional, of course, upon the termination of the strike.

The John T. Cottrell Company, while it has a large coal department, manufactures lumber, as well as dealing in unfinished stock, and though it was able to use some horses several trucks were hired. Some of the deliveries made by this concern are at considerable distances, and hauls of 15 miles are not infrequent. The McDuff Coal & Lumber Company was not as badly crippled as the others from the fact that it was the dullest period of the lumber trade for the year, and it was possible with the men available to keep pace with the business with a fewer number of trucks in proportion to its horse equipment.

those who require an additional supply to tide them over the period when heat is needed, with the occasional small orders from those who, from lack of resources, purchase according to the money in hand.

The first two or three days was the hardest period of the strike. It was indeed difficult to keep pace with the deliveries that were necessary through contract or emergency. The green workers were willing, but lacked experience, and this was a heavy handicap. The first day the greater part of the time was devoted to working the horse equipment with such drivers as were available and making arrangements for the trucks. Olney & Payne Bros. hired a Pierce-Arrow demonstrating truck and then a three-ton Packard truck. This gave the company four machines. The two Pierce-Arrow trucks with the dumping bodies were used to haul soft coal and the third machine of this make, which had a stake platform body, was fitted with temporary sideboards and, with the Packard, used for delivery of family orders. Next the third Pierce-Arrow truck was bought.

The Newell Coal & Lumber Company does a large lumber business, and as it was not practical to use the rented machines for delivery of stock of considerable length, so far as possible horses were used for this haulage and the trucks were used more for coal and construction material. A number of trucks, ranging from 1.5 to five tons capacity, were hired, and these were engaged for whatever periods they

The second day of the strike the companies had a fair knowledge of the delivery service each could command, and had located men who could furnish trucks should there be use for additional machines. Trucks that were placed at the disposal of the companies by friendly firms for a day or two were used while arrangements were made for those that could be utilized for longer periods, and with knowledge of the conditions a number of agents for trucks sought the opportunity to make demonstrations of a somewhat unusual character by offering to work their machines even as long as they were needed. As the companies were united in the refusal of the proposal of the drivers, and all were dealing with a like condition, there was a disposition to work the trucks to the greatest benefit, that is, letting the firm with the greatest need

Two Trucks at a Loading Machine, Both with Dumping Bodies, Showing the Possibilities of Delay Even with the Best Equipment Unless Work Is Well Planned.

Loading Two Trucks, a Pope-Hartford in the Foreground with an Extemporized Body and a Peerless in the Distance with a Quick Dumping Body, by Gravity, Showing the Value of Yard Facilities in Loading; the Loss with the First Truck Will Be Unloading.

spite this handicap the capacity and the speed of the trucks were such that there was a material gain in delivery. Handling brick, lime and cement better facilities would have made a decided difference.

The fifth day was the first of a week and Olney & Payne Bros. hired a fifth truck, a Packard three-ton machine, the Newell Coal & Lumber Company had eight trucks working, the John T. Cottrell Company six and the McDuff Coal & Lumber Company three, and with animal drivers hired the companies were able to make deliveries, so there were no serious delays.

have what was necessary for the time being, or conceding or receiving service.

By the third day of the strike the companies had good emergency organizations. Members of the companies drove their trucks and horses and the other men who were driving were generally inexperienced, but there was realization that with the hired trucks delivery could be made and business could be transacted. With but a part of the horse equipment serviceable and the unwillingness of many men to drive because of the strike the companies made ready for a continuance of the conditions for an indefinite period and based their determinations on the trucks available.

The fourth day was Sunday and the fifth day the companies began to gain slightly so far as drivers were concerned, which released for other work some of the men who had been driving. Despite the general lack of knowledge of the two cities and the several towns in which deliveries were made, and the absence of such loading facilities as would expedite the handling of the trucks, the machines gained surprising results. Only the two trucks owned by Olney & Payne Bros. were equipped with dumping bodies, and only this firm had mechanical loading equipment in its yards. All of the companies had facilities for gravity loading, but aside from family orders, which were handled with canvass bags, which could be filled during the absence of the trucks, shovelling was necessary in unloading.

With the lumber the conditions were such that instead of loading a wagon in the yard and having it in readiness to hitch horses to it whenever available, that there might be no delay, it was necessary to load and unload the truck while it was standing idle, and this caused the loss of considerable valuable time which might have been saved with loading equipment. But de-

The trucks were, aside from the two owned by Olney & Payne Bros., of the platform type with sideboards lashed to the platform stakes, and while these could be loaded where the pockets were built for gravity loading, it was necessary to shovel the coal when unloading. These were much more serviceable when the loads were in canvass bags, which could be handled by the yard men very quickly. Where the coal was not so it could be loaded by gravity it was necessarily shovelled, and only two of the demonstrated or rented machines, a White and a Peerless were fitted with power body hoists. But even with the power body hoists where the loading was with shovels there was considerable loss of time.

Olney & Payne Bros. had three loading machines in their yards, two at the wharf and the other at Darlington, all of which are used with bituminous coal. These are heavy constructions, weighing 3.5 tons, mounted on wheels, which are located at a coal pile and the coal fed to them by gravity and shovelling. A series of buckets, operating much the same as a bucket pump, is driven by an electric motor, and this will load five tons in from three to four minutes. Obviously, with the dumping bodies hauling soft coal meant

Weighing a Pope-Hartford and a G. M. C. Truck with Temporary Bodies, Illustrating the Saving with a Double Scale and the Equipment That Is Not Intended for Quick Delivery.

very little idleness, but with the extemporized bodies there was no loss while loading.

The practical efficiency of loading facilities was amply demonstrated. It was realized that with trucks it was necessary to have loading machines or to build pockets for gravity discharge, or to change the pockets now existing, and that dumping bodies were not only essential, but it was imperative that these be built with both end and side discharge so that unloading could be done in the least time possible. Under the system usually the vogue a driver reports to the yard office on reaching the yard and is given an order. He goes to the pocket where the coal is, loads his cart, returns to the office for weighing and starts. With the Pierce-Arrow trucks in the Olney & Payne Bros.' service about seven minutes was the average time for reporting until weighing, and the time required may be illustrated from one trip made to the water works at South Attleboro, rather more than five miles away, which was made in one hour and 10 minutes. This would have been a half day's work for a pair of horses and cart. Another illustration of the truck's value was when a Decatur wagon with two tons of coal, to be delivered to two different customers at South Attleboro, did the five-mile round trip with the two stops in 55 minutes. Several times loads were sent to the mills of the Samoset Company at Valley Falls, 2.5 miles each way, and the deliveries were made and the truck was back in 50 minutes.

What can be done with miscellaneous work was shown when the John T. Cottrell Company started a 3.5-ton truck hauling lath from the railroad station, a distance of slightly less than a mile from the yard. One morning 63,000 lath were hauled and at 1 a load was made up for Woonsocket, 12 miles distant. The driver was given an order to be delivered at Forestdale, three miles further than Woonsocket, and though he stopped on the road for his lunch and telephoned to learn whether he was wanted for the remainder of the day, he was back at the yard at 4:15, and took out another load and delivered it before 6. The Woonsocket trip would have taken 14 hours for four horses and two men, with the overtime pay, and the team would need be given light work the following day. In this instance the truck did more than a day's work in hauling the lath, it did a day's work to Woonsocket, to say nothing of the additional run to Forestdale (which was originally to be sent by freight), and it made another delivery that would have taken at least twice the time with horses, and all this with lumber.

The experience in lumber haulage, however, was that special equipment was needed so that there should be no time lost in the yard, and the unloading expedited as much as possible. Some of the dealers believe that a truck might be adapted to use as a tractor and some of the horse wagons utilized as semi-trailers when long stock is to be carried, so that these might be loaded in the yard and made ready for hauling whenever a truck is available, and that with short stock it is practical to pile the loads in the yards on dead wagons so equipped that the transfer can be made with little or no loss of time in the yard.

As will be noted from the illustrations, the conditions of the yards as a whole, so far as traction possibilities are concerned, could be very much improved, and that in which the best loading and unloading facilities are to be found is of made land that is saturated with water at this season of the year. Despite the use of material that might ordinarily give a consolidated surface the ground is very soft and yielding, and it is cut to a depth of a foot or more, so that when frozen the ruts make the yard hauls very severe for the trucks and extremely hard for the horses. The other yards are not as bad, but they are all more or less unfavorable, especially as in some the grades are heavy. Were the roads in the yards well surfaced a considerable saving in time would be effected in loading and leaving. Most of the yards have a double scale so that two loads may be weighed at once.

The experience of the members of the firm that drove the trucks has been, these men say without hesitation, of material value to them. While they both had driven the trucks before necessity required they had merely a general knowledge of the conditions of delivery, but when they drove the machines each day they not only learned what might be done with ordinary care and discretion, but what was possible in emergencies. As one of them expressed it: "We know just what a truck will do and how it ought to be worked to afford, in our opinion, its best service. We know what time is needed for a given work and we know how a truck should be driven to protect it against unnecessary wear and damage. Not only this, but from our knowledge of animal carts and trucks we are certain that the machines will do our work, do all of it, and do it faster. What is necessary is to keep the trucks moving and to minimize the time of loading and unloading. As to the endurance of the machines, that is really something for us to give attention to and not to leave to the discretion of the men who drive them. The experience we have had has been extremely valuable to us, and I believe that it would be a decided benefit to any owner of trucks to have an intimate knowledge of just how his delivery is made and the conditions under which his drivers do their work."

Without exception the opinion prevails that the trucks have been well tried under the unfavorable conditions of an emergency and that they have been found to be in every way practical. Quite as unanimous is the belief that satisfactory means can be found for expeditious handling of the loads at either end, and that the installation of such equipment is imperative. In other words, the trucks are economical from every point of view when those owning them mean to make the most of them. While the question of maintenance and upkeep has not been considered in this trial it is realized that the machines must be well cared for to endure, but with practical methods it is known that they will give continued service. Trucks will be bought and bought quickly as a result of the experience, that is certain, and it would not be surprising if a co-operative garage was an outcome as well.

BOSTON'S TRUCK SHOW THE BEST OF YEAR.

Sixty Makes of Vehicles, Four New to the Industry and 17 Not Before Seen at This Exhibition, and 60 Accessory Exhibits, Will Be Shown.

THE display of motor delivery wagons and trucks to be made at Mechanics' building, Huntington avenue, Boston, beginning at 8 in the evening of March 19 and concluding the night of March 26, will be the most interesting and attractive exhibition of the kind ever held in New England, when regarded from the viewpoint of automobile vehicle development. But it will have many other aspects that will make it of unusual importance, both to the industry and to the users of highway transports.

While it is not expected that the show will attract those who are merely curious, for there is little that will draw those who are unconcerned to such an exhibition, the experience of previous shows has proven that each year the number of visitors purposing buying has increased to an extent not even realized by those who are identified with the selling of machines.

New England is today a different market than the remainder of the country so far as the sale of power wagons is concerned. The railroad transportation is controlled practically by three corporations, which are non-competitive, and within the states service is not only extremely costly as compared with sections of the nation where there are competing railroads, but it is so slow as to be an extreme handicap to business. No endeavors by the strongest of commercial bodies or influence that have been invoked have been productive of improvement either with reference to expense or time, and with demands of patronage it has been necessary to resort to express shipments with a much greater volume of business than elsewhere in the country.

New England differs from other parts of the nation in that there are many commercial centres, each of which attracts the population of a reasonably definite area. These cities are distributing as well as receiving points, and the direct highways afford a means for transportation that is so economic as to justify their use to an extreme, and this character of haulage, as well as distribution, has been developed through the use of the motor vehicle. The New England highways have been improved by the expenditure of large sums of money by each of the states, and in southern New England the road systems have been greatly developed.

The limitations of animal haulage were not realized until the possibilities with motor trucks were known, and there is a rapidly increasing conviction that with change of facilities that are entirely reasonable and within the resources of the majority of busi-

Mechanics' Building, Huntington Avenue, Boston, Where the Annual Show of the Boston Commercial Motor Vehicle Association Will Take Place, March 19-26, Inclusive.

ness enterprises a decided saving can be made.

Last year the number of motor wagons and trucks placed in service in New England was, conservatively estimated, at least three times that of the previous year, and there is reason to believe there will be at least the same ratio of increase of sales made as compared with 1912. It is certain enough that there are many firms and business men who have been converted by the practical experiences of others, and they have made observations that convince them of the serviceability of machines.

The coming show will be from every point of view an attraction to the man who is engaged in business. There is no apparent reason why there should not be economy in a delivery or haulage service. The progressive man of affairs, though he realizes that any financial statement of his service will show no revenue and a constant expense understands that if this cost can be reduced, even at a material initial expenditure, it is a saving in every sense. The effects of competition impel better delivery service, for this is one of the greatest essentials making for satisfaction. This applies to practically every business enterprise of consequence, and it is this knowledge that will impel the insight of those directing them into the qualities of vehicles that may be adapted for their use.

Officers and Directors of the Boston Commercial Motor Vehicle Association.

The show will contain 60 exhibits of different makes, and these will represent at least 125 power vehicles of differing types, sizes or models, which will range from the very light package wagon to a seven-ton truck. Practically every form of construction will be shown, and the power will be by both steam and gasoline engines and electric motors. While this number of vehicle exhibitors will be four less than in 1912, the show will be in every sense larger, and it will represent the cream of the power wagon industry. More makes were shown at both New York and Chicago, but there were at each of these exhibitions a number of machines that were seen for the first time. Though total makes of vehicles shown may be regarded as the basis by which to judge a show, it is a fact that the real measure is the character of the displays and the attraction they will have for the visitors.

The 60 exhibits will consist of 51 makes of gasoline wagons and trucks, eight makes driven by electric power, and one using steam for propulsion. There will be seen a representation of electric vehicles which will be the equal of any seen at any exhibition in America.

The exhibits of gasoline machines will include two that have not before been shown, the B. M. C., which will be seen at the stand of the Boston Motor Company, and the Sowers, which will be the exhibit of Sowers Motors Truck Company. There will be one electric line that has never before been shown, the Edison, made by the Edison Electric Vehicle Company, while the Couple-Gear trucks and tractors, and the Eldridge front-drive electric carts and caravans, the displays of the Eldridge Manufacturing Company, have not been previously shown this year. The Couple-Gear machines are standard productions and are well known, but the Eldridge has not been shown at an exhibition, although a number of these have been in use in Boston and vicinity for a considerable length of time. The Stanley line of steam delivery wagons was shown at Boston last year, but not since that time at any show.

There will be a considerable number of gasoline wagons and trucks that will be new to Boston. These include the Adams wagons and trucks, shown by the Power Truck Sales Co.; the Best and Flint wagons, built by the Durant-Dort Carriage Company; the Hercules wagons, made by the Flanders Motor Company; the Jeffery, produced by the Thomas B. Jeffery Company; the Stewart, shown by H. Ross Maddox of Medford, Mass.; the Sullivan wagons, built by the Sullivan Motor Truck Company; the Lippard-Stewart wagons and the Schacht trucks and wagons, shown by the Whitney-Barney Company; the Overland wagons, shown by the Connell & McKone Company; the Little Giant wagons, built by the Chicago Pneumatic Tool Company; the Marmon wagon, shown by the Frank E. Wing Motor Car Company; the Smith-Milwaukee trucks, shown by the A. O. Smith Company; the Standard trucks, shown by the Whitten-Gilmore Company; the Universal wagons and trucks, shown by the Universal Motor Truck Company; the Vulcan trucks, shown by the Bessemer-Vulcan Motor Truck Branch; and the new electrics will be the Atlantic trucks, built by the Atlantic Vehicle Company, and the Buffalo wagons, built by the Buffalo Electric Vehicle Company, shown by the Dodge Motor Vehicle Company. This will make a total of 21 machines that will be practically, if not entirely, new to New England, or at least new since the last exhibition.

One feature of the show will be the exhibits of special bodies, some fitted with manual and power hoists for quick dumping, some designed for haulage of packages and containers, and others intended for more general work. While the majority of the body equipment shown will be built for practical use, there will be seen some admirable examples of workmanship and finish. Equally as interesting as the chassis will be the bodies, and these will no doubt receive the careful attention of the visitors. The number of exhibitors of accessories, equipment and supplies number 60.

THE TRUCK SHOW EXHIBITORS ALPHABETICALLY CLASSIFIED.

Gasoline Business Vehicles.

Adams, Power Truck Sales Co., Worcester, Mass.
Alco, American Locomotive Co., 567 Boylston St.

DISTRIBUTE STOCK WITH SEVEN-TON VULCAN.

THE John T. Connor Company, wholesale grocer, Boston, Mass., which is probably the largest concern of the kind in New England, has used since last September a seven-ton Vulcan truck, which is one of the largest machines in Boston, with a degree of success that is surprising, considering the conditions in which the work is done. The present purpose of the company is to utilize additional trucks and it may, because of the possibilities for transportation, change the location of some of its warehouses.

The business districts of Boston are notorious for the narrow streets, and because of the necessities of traffic haulage has been regulated to such an extent that it is impossible to utilize any kind of conveyance to its greatest capacity, which absolutely prevents using the truck so as to realize its fullest economy. Yet there is no question of its efficiency and its economic value in the service in which it is used.

The Vulcan Seven-Ton Truck Used in Distribution by the John T. Connor Company, Wholesale Grocer, to a Chain of Stores in Boston and Vicinity.

One of the warehouses, where the groceries are stored, is in Utica street, directly across the thoroughfare from the Boston & Albany freight houses, and it extends through to South street. A great deal of flour is received by railroad and is transferred by cart from the freight houses to the storehouse, this necessitating just the same handling as though the distance were miles, and requiring more time than might be imagined because of the congestion. As may be assumed, the delivery sections of the freight yard are crowded from early in the morning until well into the evening, and with wagons backed to the buildings at either side there is a passage only sufficient for one vehicle to pass through. This passage can only be maintained by turning the horses at right angles to the carts.

That there is but a narrow lane between the vehicles means that the movement of every conveyance is badly restricted, and as there are often many waiting for vacancies at the delivery platforms it is necessary for the police to keep the other side of the street as free as possible. They will permit the use of carts when the horses can be turned at one side, but motor trucks that are longer than carts cannot be used. As might be assumed, any unusual congestion of the street immediately becomes a serious matter, for it means the loss of time for hundreds, representing in the aggregate thousands of dollars. Side loading is out of the question because of the platform space required and there can be no remedy unless it is to widen the street by encroaching upon the railroad or the private property.

Because of the conditions at the freight house the big Vulcan cannot be used in any service that will take it into Utica street and so its usefulness is confined to the haulage of butter, eggs and potatoes. South street is wider and the conditions for loading are more favorable. The machine cannot be backed to the sidewalk, but it can be side loaded, and the class of freight carried can be handled comparatively rapidly. The work is slower than end loading, but the packages can be lifted and placed in the truck without a great deal of exertion.

The Connor company has a chain of 115 retail grocery stores in Boston and vicinity, and it is necessary that the stock of all of these, or at least the greater part, be distributed according to the demands, and it is for this distribution that the truck is used. Cases of eggs weigh about 60 pounds each and tubs of butter about 76 pounds, and 120 tubs and 100 cases will make a load slightly in excess of the rated capacity of the truck. When this class of freight is hauled the distribution is usually to the suburban stores, but often three and sometimes four loads are carried out, while any one of these loads would be all that a horse cart could take out in a single day, though it might be possible to take care of two loads if the hauls were not long.

At a storehouse in Charlestown potatoes are stored and these are distributed in a like manner. The potato sacks weigh 120 pounds each and 115 sacks make an average load, which is about twice what would ordinarily be carried by horse wagon. The body space is

sufficient to take 120 sacks, but this number would overload the truck and though the distribution may be begun within a distance of three or four miles, it is not the policy of the firm to permit overloading.

The average daily mileage of the truck, which has a maximum speed of 12 miles an hour, is between 50 and 60, although in a number of cases 75 miles have been traversed. Outward trips may go as far as 12 to 15 miles from the warehouses, but the distance may be double that indicated by a direct line on the map. The economy of the long hauls, despite the loading and unloading conditions, for practically at every stop the driver and his helper have no assistance and at best it is seldom practical to unload direct from the machine to the store, is unquestioned.

Early last summer the company, which then had all its haulage done by contract, decided to try a truck, and a Commer machine was demonstrated by the Dodge Motor Vehicle Company. This proved very satisfactory and the truck was hired to do regular haulage until the Vulcan was delivered. It was worked about three months and with the delivery of the Vulcan this machine was placed in the service described. The contract haulage was continued and it is the vogue now, but it will be somewhat reduced this spring when a new truck is delivered, as is now the intention of the company. The Vulcan truck is garaged at the service station of the Vulcan-Bessemer Motor Truck Branch in Church street, and a service attention is given it there. A reasonably accurate account of the work performed is kept and while a system has not been devised it is known that the truck is doing what would not be possible with animals.

ESTABLISHES BRANCH FACTORY.

Body Builder Takes Over Plant in Detroit Formerly Occupied by Grabowsky Company.

The Edward G. Budd Manufacturing Company, Philadelphia, Penn., maker of automobile bodies, will shortly establish a branch factory at Detroit. The advantages of being in the heart of the industry became apparent when an opportunity presented itself to purchase the plant formerly occupied by the Grabowsky Power Wagon Company, and the Budd Company has taken possession of this. The property consists of 8.5 acres of land with buildings and the price paid was $110,000. The appraised valuation is said to be $140,000. Contained in the purchase is a modern reinforced concrete building, four stories high, with 72,000 square feet of floor area, and a modern power building. There are also several sheds which the Grabowsky company utilized for storage purposes.

The Budd plant in Philadelphia will be operated to supply the trade in the East and south of Toledo, O., while the Detroit branch will handle the Michigan business and part of the West. By next May it is anticipated the production will total 30 completed bodies a day. The Edward G. Budd Company was organized in June, 1912, with capital of $500,000, all paid in, and manufactures pressed steel bodies for commercial and pleasure cars.

ECONOMICAL OF GASOLINE.

Knox Martin Truck Demonstrates Its Ability Under Peculiarly Trying Circumstances.

A Knox Martin tractor, built by the Knox Automobile Company, Springfield, Mass., in the service of a lumber company at Sacramento, Cal., was recently put to a severe test which demonstrated in a most convincing manner the wonderful pulling power of this type of vehicle. A large derrick at work on the lumber company's new wharf broke under the strain and the nearest one available was 16 miles away. Its length was over 70 feet and would have required two flat cars to transport it by railroad.

The tractor, however, easily pulled it out of its location in a large heap of scrap iron and delivered it at the wharf in a little more than 1.5 hours. The derrick was so firmly imbedded in the scrap iron that the tractor had to drag it through 10 feet of the pile before it was free. The demonstration was all the more remarkable when it was found that the tractor had averaged over four miles to a gallon of gasoline in spite of the heavy burden.

A TRAVELLING BOOKCASE.

Library in Hagerstown, Md., Inaugurates Innovation for Supplying Readers in Rural Districts.

A motor truck has been put to a novel use by the trustees of the public library of Hagerstown, Md., who recently purchased a "travelling bookcase" to deliver books from house to house in the rural sections. As far as is learned this is the only automobile of its kind in existence. It was built to order by the International Harvester Company of Chicago, and when the doors are closed the machine looks exactly like a dry goods or grocery delivery automobile.

The vehicle has a capacity of 1000 volumes, some being carried in cases to be left at the various substations, while others are arranged on shelves on either side in order that selection may be made as the machine stops in front of farmhouses and homes in villages too small to maintain sub-stations. The car is of 20 horsepower.

C. W. Martin, manager of the motor truck department of the Goodyear Tire & Rubber Company, Akron, O., maker of Goodyear tires, has announced that there is to be a reduction of 10 per cent. in the cost of Goodyear truck tires. This he states is due to the immense production of the plant, as a result of the demand for Goodyear truck tires.

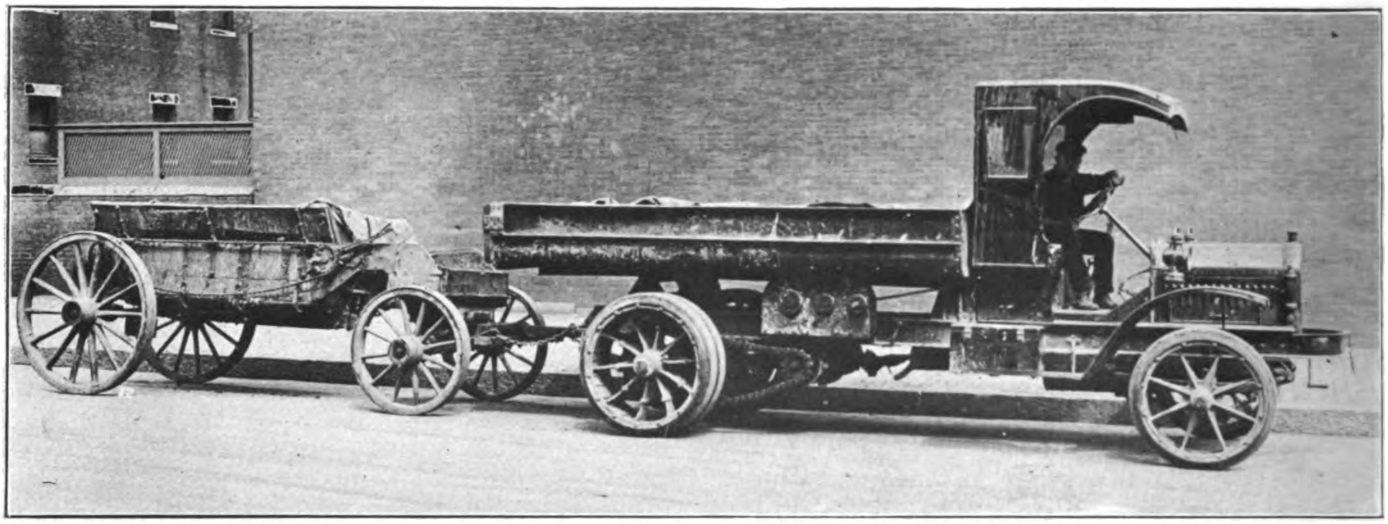
TRUCKS LOWER HAULAGE COST A THIRD.

Without Change of Facilities Adapted for Horse Service Warren Bros. Company, Paving and Roofing Contractor, Attains Large Ratio of Economy at Cambridge Plant.

THE utilization of motor trucks and wagons with facilities and equipment that have been developed for animal vehicles is the problem business men who consider economy of transportation invariably have to meet. The natural conclusion is that there should be as little sacrifice as is possible if the animals are to be displaced, and with the majority at least the inclination is to minimize expense in whatever changes may be regarded as necessary.

There are few who will regard a translation of a transportation department of a business from the same viewpoint that they will any other proposition that has to do with economy. Lessened cost of production, for instance, is always understood and is seldom a subject for issue, but most men are inclined to doubt the efficiency and utility of the power and are doubtful as to the expense that they are justified in incurring. Without question most of them believe and to apply whatever will be useful and reject what may be impracticable, and creating a system that will be both efficient and economical, may not appeal to those who would dispose of the problem of making a purchase. But it is certain enough that those who give an attention to haulage equal to that given to any other department of a business will find at least a reasonable saving in every way practical.

When a transportation service is comparatively small and the demands vary decidedly at different seasons of the year, the solution, so far as the use of motor wagons is concerned, is far more difficult to attain than one where the requirements are reasonably constant. The large concern often has a specific character of work that is not variable, and work can be depended upon, but where there is a considerable elasticity necessary and a loss results from all excess equipment whenever it is idle, the careful manager



Five-Ton White Truck with Special Dumping Body, and Two Cubic Yard Watson Wagon Converted as a Trailer, Used by Warren Bros. Company, Paving and Roofing Contractor, at Cambridge, Mass., Plant.

that prudence demands that they make expenditure as they are convinced by results, and they feel that they cannot accept anything less definite than their own experience.

It is certain enough that a progressive man will make careful estimate of any division of his business and will be satisfied to base his judgment on his knowledge. For instance, he will accept a statement as to the productiveness of machine equipment or tools, and he knows that it will be impossible to realize the production unless he adapts his methods to utilize them to capacity. Many men will study operation and use, and even improve upon what is expected through clever adaptation and handling.

The possibilities of studying the transportation departments of varying enterprises, gaining a sufficient knowledge of methods of operation to make analyses, hesitates to make a change, even though there be a probable aggregate saving shown in the estimate.

The Warren Bros. Company, known throughout the United States as a street paving contractor and affiliated with the Warren Bros. and the Warren Construction Company, has its executive offices in Boston, and its refinery and yard is in Potter street, Cambridge. The company has two asphalt refineries in California and the asphalt is shipped across the continent by rail and refined. The crushed stone is received in railroad cars, the cement by rail or vessel, and gravel is brought by barge from Long Island. This applies to the Boston plant. Wherever the company has contract for work such apparatus as is necessary is sent there and when this work is completed it is moved, so that in a considerable number of cities the firm may have for varying lengths of time construc-

tion gangs and tools and machinery necessary in whatever form of highway or sidewalk building may be undertaken. There are, of course, some plants that remain for considerable periods, but these are where the contracts are large. Usually such materials as are needed and may be secured at less expense are obtained as close to the work as is possible.

Where the plants have been located the haulage has been done with horses and carts contracted for, and this has been economical from the viewpoint of the limited time needed and the large expense for maintenance of animal equipment when not required. The Boston plant, however, is a permanent installation and the company has at Cambridge such facilities as are necessary in connection with street and sidewalk building and flooring and roofing. This has been developed to economically receive and store and prepare material for any work. For instance, the gravel received by barge is stored in large elevated bins or pockets from which the greater part will discharge by gravity, for the yard is on the water front. The car loads of asphalt are unloaded from a spur track in front of the yard. Car loads of crushed rock are brought over a subway and the stone dropped from the bottoms of these cars to smaller cars that are on an inclined cable railway in the subway. The cars are drawn to the top of a trestle and dumped into pockets or bins, or stored in piles under the trestle, and the sizes are kept separate. Cement is brought in by cars on the spur track.

The facilities at the yard have been briefly enumerated to indicate that where it is possible the company has equipment to expedite the handling of whatever material is kept in quantities, and during the busy season of the year these supplies are constantly arriving. The plant cannot be regarded as attractive save from the viewpoint of practicality, and while the methods might be considerably improved upon were a new yard to be equipped with the facilities that experience has demonstrated are desirable, it is doubtful if the economy resulting from a change in the present equipment would justify the increased investment that would be necessary. When the requirements of the business demand there is no reason to believe that anything else than improvement will be considered.

The principal operations of the company from the Cambridge refinery and yard are confined to what is known as the metropolitan district, which includes the city of Boston and the adjacent cities of Cambridge, Chelsea, Everett, Malden, Waltham, Newton and the towns of Brookline, Weston, Revere, Milton, Arlington, Dedham, Melrose, Watertown and Needham. Not all of these municipalities are covered by the company in its work, but it can be said that a radius of 10 miles from the centre of Boston will include the area in which the company makes contract for construction. The greater part of the work is probably within a radius of seven miles, but occasionally, if the contract is of sufficient proportions, it is undertaken as far as Lynn.

At greater distances contracts are made and a temporary plant is installed, so that it is not necessary to supply the material from the Cambridge yard, but for Boston and vicinity the surfacing is mixed and carted from that point. The reason the carting distance is limited is that it is necessary to have the material heated to a consistency that it can be worked, and at a reduced temperature it is not practical to use it. The bithulithic paving is a compound of crushed stone, gravel and asphalt, and this is laid on a foundation of crushed stone. Sometimes the company makes contract for the entire construction and at times merely the surfacing is provided. There is a variance in the character and quality of the work according to the uses to be made of it.

The construction can only be made when the weather is dry, and because this limits the period when work can be done it is necessary to have the haulage expeditious. When a street or sidewalk is excavated for the foundation course the lower course of stone is laid and consolidated by rollers, steam rollers up to 15 tons weight being used. The surface is next supplied and this must be prepared at the yard. The process of preparation is interesting. The necessary volume and size of crushed stone is specified and this is taken from the bin and is dried by a blast of heated air. It is carried by a bucket elevator, and after it is dry a given quantity of gravel is added and on this is poured asphalt heated until it is practically a liquid. This asphalt is a refined product and when it is liquified it must be to a specified temperature to have sufficient fluidity. But it can be destroyed by overheating. The stone, gravel and asphalt are placed in a mixing machine that revolves, and turned until the asphalt has thoroughly coated the solids, and then it is a mass with the voids completely filled with the bitumen. When mixed the material has a temperature considerably in excess of 300 degrees, and is loaded by gravity from the mixer, the vehicle being backed into a recess in the building that will receive a cart or truck with but little room above or at either side.

Much judgment must be exercised in the mixing of the material. The stone must be dry to insure the asphalt adhering to it, and there must be a sufficient volume of solids. The temperature must be such that the stone and gravel will not settle in the soft bitumen, and when the surfacing is delivered for use it must be of such a consistency that it can be laid evenly and have the desired proportions throughout. The surfacing is never sent away at a temperature of less than 300 degrees, and the workmen mixing the material generally work with thermometers to be certain that the heat is within the limits fixed. The mixture when prepared will cool very slowly, and it may be carried considerable distances without a sufficient loss of temperature to prohibit its use. If the material should harden slightly at the top, sides or bottom the bulk of it has a heat that will restore the cooled portion to a condition of usefulness by hand mixing, and even in cold weather, where the foundation has been protected against dampness, the surfacing may be laid.

Of course there is a standard of desired temperature

and when the material can be delivered at the job at this standard the most satisfactory work can be done. The time of cartage is a factor of considerable importance with reference to heat, and when received it is necessary that the material be spread as rapidly as is practicable. Once distributed the paving will cool quite rapidly. Obviously it is necessary to have a sufficient number of men at work on paving to handle the surfacing as it is delivered and when there is delay in cartage there is loss of time for the men, which the company must bear. A part of the system is to have the material mixed, hauled, delivered and laid so there will be a minimum of lost time, and with work in progress in several places careful judgment must be exercised.

With long experience a work is planned so that it can be completed with a given number of men, apparatus and tools and material and transportation, and the surfacing is mixed as it is required, the haulage being determined with a knowledge of conditions. At the yard at Cambridge the company kept 12 horses,

White Five-Ton Truck, Used for Paving Material Haulage, Loaded with Apparatus, Tools and Supplies for a Distant Construction Job.

these being worked in teams of two each. The material was hauled in Watson wagons of bottom dumping construction with a capacity of two cubic yards each, these loads weighing about three tons, which could be driven on to the work and the mixture dumped approximately where it was to be spread. Watson wagons were used because it is impossible to handle the paving material quickly unless dumped, and it cannot be shovelled or moved as can almost any other form of a load. Even with such equipment it was necessary to use more or less force in dumping when the material cooled slightly. Where the work was of sufficient proportions, such as a street, where from 800 to 1000 yards of surface could be laid a day, it was necessary to hire additional horses and the wagons were operated wherever possible with a headway of about 10 minutes, this affording a supply that could be advantageously worked by the paving gang.

But while this theory was the basis of estimate when contract was made, it was found in experience that there were numerous delays with the animals, and this lost time represented a considerable amount of money when the total was even approximated. Besides this, if the wagons did not arrive at the yard in regular order the material could not be worked to advantage, for the mixing machine could not be filled with fresh stock until dumped. Were the elevator and mixer to be built again to meet the requirements for the greatest economy it would be with facilities for dumping the mixer and keeping it at work, so that a load or two might be in readiness if there were delay of the vehicles, and the carts could be loaded without waiting whenever they reached the yard. But to make this change would entail a comparatively large expense, and it was believed best to endeavor to maintain the wagons as near a schedule as possible, rather than have an investment that would not be always productive. In other words the company had to choose between the loss through delay of the wagons and men or install facilities that would necessarily be idle a part of the time. The choice was to continue the use of the mixer.

The work of the company is usually carried on with a foreman or superintendent in charge of each job, and the yard, which is in charge of Supt. Sutcliffe, is expected to deliver the material, tools and supplies wherever these may be required. Naturally the number of jobs varies and at times it is necessary to send surfacing considerable distances. The longest distance that material has been supplied from Cambridge by horse wagon is Lynn, and with the work beginning at 7 in the morning and a four-hour haul for the horses, it was necessary to start with the first loads at 1 at night, and one round trip was a day's work for the animals and drivers. More or less work is done before and after the usual working hours of the day, especially at the season of the year when conditions are favorable for outdoor construction. As the paving material must be delivered mornings when the gangs are ready for work it will be understood that the demands are dependent upon the distance from the yard, and the hours for the yard gang and the drivers are governed by circumstances. But the purpose is to supply every need promptly, which means occasionally, at least, long days and hard work.

About two years ago Supt. Sutcliffe, who is also traffic manager for the company, began to investigate the possibilities of motor trucks and wagons and after a period of continued observation and careful study of the uses of machines in service that was somewhat similar to his own he prepared estimates of what he

believed could be accomplished with the facilities he had. He was conservative in his deductions and he decided that a five-ton truck must earn $15 a day to be preferable to animal vehicles. He had at the yard a machine shop with a working force of about 25 men and resources for practical work, which was an advantage insofar as maintenance was concerned, and he knew from experience with machinery the necessity of consistent and careful upkeep. There was a reasonably satisfactory building available for a garage and he believed that with practically little change he could make advantageous use of trucks. The analysis was submitted to the company, but the officials were not at that time ready to make the change.

Last spring the company called upon him for an opinion as to what might be done with trucks and though he had continued his observation and investigation he did not believe that he was justified in changing his original estimates. These were submitted and, after consideration, the company authorized the purchase of two five-ton trucks and a 3000-pound wagon, this being regarded as equal to the enimal equipment. White machines were ordered and delivered about the first of July, the trucks being fitted with special bodies that are practically shallow steel pans 11 feet length, six feet width and 18 inches depth, having a capacity of 100 cubic feet, which is approximately equal to five tons, for the paving mixture weighs about 100 pounds to the cubic foot. Both trucks are equipped with the White power hoist and the bodies may be elevated to an angle of 45 degrees, which inclination is necessary to dump the surfacing material. The tail boards of the bodies may be entirely removed to permit the complete clearance of the load. But when the trucks were received it was decided to adapt what is known as a caravan or stake platform body to them, that they might be used for other forms of haulage when not needed for paving. In 1912 the company's paving work continued to Jan. 1, and it will be resumed as soon as the highways dry sufficiently, perhaps in May, but there is more or less repairing that may be done much earlier. During this comparatively inactive period it was believed that other uses could be made of the machines. The 3000-pound wagon was equipped with a regular stake platform body. This was fitted with single and dual pneumatic tires.

The company utilized the trucks as it had its horses and carts and adapted several of its Watson bottom dumping wagons as trailers. This was done by fitting a drawbar about three feet long that took the place of the wagon pole, and in the end of this wooden pole was a slot several inches in length. The pole end was secured to the centre of the rear chassis frame member by a pin dropped through the slot in the pole end, and chains were extended from the ends of the equalizer mounted under the extension that carried the pole to the ends of the side members of the chassis frame. The slot permitted the pole to go forward sufficiently to attach the chains, and by the pole the trailer was steered. The chains and the equalizer gave absolutely good control.

In the use of the trailers not a little difficulty was experienced through the difference in the angle required for rubber and steel tires to lift from the grooves of or from within car tracks. The rubber, having much better traction, would lift at a comparatively slight angle, but the steel would not rise until a much greater inclination had been given the wheels. When the wagons were first used as trailers the drivers of the trucks turned from car tracks and the trailer wheels did not lift. The result was that the trucks continued on, the driver perhaps unconscious that the trailer was left behind with a wheel or two and the pole and the chains broken. Such accidents were frequent until the drivers learned more of handling the truck with a trailer, but this was largely due to the fact that the wagons were not and cannot be effectively adapted for the purposes because they are too lightly built and have too high a centre of gravity.

Dumping the Heated Paving Mixture on the Job at a Temperature of About 300 Degrees, Ready for Quick Laying.

With a truck and trailer loaded eight tons of surfacing could be carried at a single trip, and it was Supt. Sutcliffe's observation that it required but little if any more time for loading and unloading, for a trailer could be loaded while the truck was away and be ready for coupling as soon as the truck was loaded, while both could be dumped at once on the job. He found the trucks could be depended to work to a schedule and there was but little variance in time of trips, which was important for the mixing gang, and that practically the only reason for delay was when worked in combination with animal carts, for the truck equip-

ment was not sufficient during the busy periods. The truck he found to be equal to at least three horse wagons, and under some circumstances to four, and with the trailer added this brought the work to that of five or more wagons. Of course the capacity was somewhat dependent upon the length of haul. Besides the trailer wagons could be used for hauling the small portable furnaces used for heating material for repairing, tools, and, in fact, any supply that was needed. This was without loss of the usual load of paving and was a distinct saving of time as compared with horse work.

From time to time, when necessary, the trucks were sent away on jobs a considerable distance, at one time to Haverhill, 38 miles from Boston, where they were worked from the temporary plant located in that city. The trucks carried loads of tools and equipment both ways, which was a saving of the freight, as well as having the use of these without delay. Not only this, the company had the benefit of the trucks on the contract, doing the work at Boston with horses during the time the machines were away.

The 3000-pound wagon was given the work for which two horses and two single express wagons were used. One of the wagons made daily trips about Boston, taking a half day for a round of collections, and this has been reduced to an hour and a half with the motor outfit. The delivery of small orders, sending out material or tools needed for the floor and roofing jobs and the like, taking practically the remainder of the time.

In fitting the trucks for the installation of caravan bodies it was found necessary to remove the power hoist body trunnions and the mechanisms and fittings assembled with the chassis frame and to mount these on a heavy frame of six-inch steel channel, exactly as on the chassis originally. The frames are so constructed that they are bolted on the chassis, raising the bodies six inches above the normal height. When desired the bodies are lifted with the frames from the chassis, leaving the hoisting mechanism without change, and these were replaced with the caravan bodies, the work being done by derricks and with very little labor. This dual body installation has worked out very satisfactorily from every point of view.

Supt. Sutcliffe says that he has kept careful record of his trucks and the work performed with them, but points out that it is impossible to demonstrate efficiency by mere cost figures because the conditions with reference to work cannot well be averaged, even with one equipment. Not only this, there are so many variable factors and service that cannot be shown in its actual value, that no positive standard of worth to others can be given. He estimates that a five-ton truck will replace three and sometimes four two-horse teams and wagons, and when used with trailers five and possibly six, according to the character of the work and the distance, and says that this might be improved upon with a change of yard facilities that would entail a considerable investment. He maintains that a truck of this size must earn $15 a day to make it profitable, or really to pay for itself, and says that with his work this figure is justified by experience. After six months' service he went over his records carefully and found that he had accomplished a saving of approximately 33 per cent.

He had a well kept record of horse cost for the 18 months prior to the installation of the trucks, and very good figures for a considerable period before, and his statement is based on accurate knowledge. Rather surprisingly, he states that from his first half year's experience he has had no reason to change his original estimate of the value of trucks to the company, and that his first figures are, to his mind, absolutely well founded. He has allowed for an overhaul of the machines in this statement as well, for this work is to be done during the time of least activity of the work.

The company has ordered a third five-ton truck, which will be delivered before the opening of the season, and this will be similarly equipped with regard to the body. The horse equipment has been disposed of save two animals that are used in yard haulage and are being kept until the price set upon them is offered.

Relative to depreciation and maintenance, Mr. Sutcliffe believes that a truck ought to endure as does other machinery, provided it receives the necessary attention and is protected, and with his facilities he proposes to minimize expense and insure endurance by systematic care. The men driving the truck were horse drivers and have proven themselves efficient and capable. One of the best machine shop mechanics has been assigned to the work on the machines and is assisted by the drivers, who are in this manner acquiring practical knowledge that will be very useful.

The transportation department of the Warren Bros. Company is operated with a view of economizing from every practical viewpoint, but the machines are never sent out overloaded and they are not worked when a repair should be made. Supt. Sutcliffe says that it is cheaper to do repairing when its need is known and not take a chance in causing damage through neglect.

KISSELKAR SAVES TOWN.

Hauls Fire Apparatus from Neighboring City 14 Miles in 48 Minutes.

To the fact that Harry A. Fish, a miller of Woodbury, N. J., is the owner of a three-ton KisselKar truck, the village of Swedesboro owes its existence. Swedesboro, which is situated 14 miles from Woodbury, was threatened by a serious fire when an appeal for help was made to the fire department at Woodbury.

A hasty consideration of the request convinced the Woodbury chief that it would be folly to attempt to drive with horses with any hope of reaching the scene in time to be of any service. Mr. Fish's truck was thought of and was pressed into service. It hauled the apparatus and 25 men to Swedesboro in 48 minutes, arriving in time to prevent a conflagration.

PEERLESS TRUCK HAULS PERRY MEMORIAL.

THERE is national interest in the monument that is to be erected to the honor of Oliver Hazard Perry, the Rhode Island naval hero, and which is to be dedicated on Sept. 10, at Put-In Bay, Ohio. It was in this bay that the youthful officer fought the historic engagement that was crowned by his victory and the elimination of English jurisdiction so far as its navy was concerned from the water of Lake Erie and from the Great Lakes. The monument is a tribute of the nation, and in the formalities that will take place on the centennial of this memorable conflict, fought Sept. 10, 1813, practically all of the states of the Union will participate by representation. The occasion will attract many thousands of people and in many of the states the day of dedication will be a special holiday.

At Erie, Penn., the hulk of the Niagara, to which Perry transferred his flag when he abandoned his sinking flagship, and which was raised from beneath the waters of Misery Bay after nearly a century's submersion, is being repaired and made ready for a cruise in Lake Erie the coming summer. And in the town of Milford, Mass., the Massachusetts Pink Granite Company is hewing from its quarry the stone with which the imposing base and shaft of the Perry monument will be built. The Niagara will, no doubt, be an object of keenest interest for a comparatively brief period, but it is expected that the monument will be as enduring as are the rugged hills from which its granite blocks have been wrested.

Four-Ton Peerless Truck Hauling Rough Blocks of Stone for Commodore Perry Memorial at the Quarry of the Massachusetts Pink Granite Company, Milford, Mass.

The quarry of the Massachusetts Pink Granite Company is high on a commanding eminence, for on the crest of this hill is found the finest quality of stone. Here the solid rock has been exposed, and the quarrymen with drill and explosive break out blocks that are as near the shape required as they can be loosened. For years the company has carried on business, and the rough stone from the quarry has been hauled two miles to the works, where it is shaped and dressed. The works are in a valley and were so located to be at the railroad, for practically all of its stone is shipped, but it is impossible to get the tracks nearer the quarry save at an expense that would be prohibitive.

It might be possible to construct a railroad that would bring the stone down by gravity, but it would require very certain power to even draw back the empty cars. The business of the company is constant and dependable, but even the building of a road from the quarry to the works has never been considered, because of the expense, and so the rough stone has been hauled the two miles by horses and on heavy carts whenever the conditions would permit. Between the quarry and the works there is a cart path, and despite the fact there is a gradual descent never less than four and sometimes six horses were used, and two round trips could be made in a day. The carts were fitted with brakes and these were at times necessary because of the irregular character of the path, which has extremely sharp descents. There is but one stretch of the way that the horses climbed a grade while going from the quarry to the works, and were there much work of this kind the teams used would need be of at least six horses under the most favorable conditions, and perhaps as many as 10 would be necessary during storms and when the ground is wet and soft.

Now the company has a five-ton Peerless truck doing the work that was done by horses. Not only this, but it is doing it well, and under conditions that are about as unfavorable as could be experienced. The machine is kept at the works and day after day it is climbing the hill to the quarry and bringing down blocks that are to make the Perry monument. These blocks when dressed and finished weigh 4.5 tons, and when rough quarried they will range in weight from 11,000 to 12,000 pounds. The stone is blasted in the quarry and then raised by derricks. The truck is backed under them and the granite is lowered carefully. Then it is hauled to the works and there lifted from the truck by derricks.

The rock is then dressed and when finished it is lifted on to flat cars and shipped. The handling requires considerable time, both at the quarry and at the works, and the trips cannot be quickly made because of the loads carried and the condition of the path. The driver of the truck, a thoroughly experi-

enced man, says that the road is the worst he has ever driven over, and he believes himself qualified to judge. He has hauled chip stone, cinders, gravel and the like from the works and filled some of the worst places in the path, but despite this the road is but little better. for, there are places where water accumulates and will not be dry before the late spring. It would require months for a good sized gang of men to make the path anything like even an ordinary country way.

Over this the truck is making eight trips daily, a distance of approximately 32 miles, and is delivering four times as many blocks as could be hauled with a team of four horses, and doing it well. If the path had been even levelled there would be a decided gain in time, for the grades are such as to cause very hard work. As might be imagined the horses and carts have cut the road until the ruts are almost axle deep. The driver says that if he has time he can carry enough material to fill the holes, and that it may be he will level the surface of the path so that it may be regarded as passable. But it will be an undertaking of no small proportions. He maintains that this is the only truck in use that is used for haulage and private road building.

So far as the economy of the machine is concerned its work is evident. Just what the cost will be as compared with horses cannot be determined until after a service of considerable length and an accurate knowledge of cost, but this will need be placed against the decidedly uncertain expense of horses. Expedition in getting the Perry monument stock out and finished was what prompted the use of the machine, and according to the observations of the officers of the company the memorial will be quite as important in its affairs as it will be to the people of the nation, marking, as it does, a great progression in business development.

OVERLAND DELIVERS MILK.

Capacity of the Horse Drawn Equipment Has Been Increased Five Times.

A dairy company of which Col. George H. Pippy of San Francisco is the head, has put in service an Overland delivery wagon, made by the Willys-Overland Company, Toledo, O. While the car was purchased to advance the business interests of the firm, the acquirement of the machine also has a humane side to it. It is being exclusively used to deliver certified milk. The law of California requires that certified milk must be delivered as soon as possible after reaching San Francisco.

The Overland delivery wagon meets the milk at the depot and within five minutes after its arrival it is on the way to the consumers. The success with the first motor wagon used has been shown by the increased demand for certified milk and now, instead of the shipments being limited to the capacity of the horse delivery wagon, they have been increased five times by the new means of transportation.

TO OPERATE STAGE LINE.

Spokane Man Organizes Company to Compete with Railroad Transportation in Washington State.

Convinced by a short experience with an automobile stage line from Spokane to Reardan, Wash., a distance of 24 miles, that good roads allow actual competition with railroads, H. S. Hawley states that he is planning the organization of a $100,000 corporation to handle business on a larger scale. Among the things that the new corporation plans to do are the following:

Replace the present stage with several interurban road motor cars of an advanced design, similar to an ordinary railroad coach; extend the present service to Davenport, Wash., as soon as Lincoln county extends its stretch of permanent highway from Reardan to Davenport, and handle not only passenger and express business, as at present, but also a line of fast freight. Mr. Hawley makes the run between Reardan and Spokane in 1.5 hours.

ANOTHER UNIVERSAL FACTORY.

Detroit Concern Secures Additional Capital and Will Materially Increase Production Facilities.

Fred K. Parke, secretary, treasurer and general manager of the Universal Motor Truck Company, Detroit, maker of Universal trucks, has announced that the company has been incorporated under the laws of Delaware, the capital being $1,200,000, of which $500,000 is preferred and $700,000 is common. All stock has been sold and work will be begun at once on the erection of a factory quite as large as the present plant.

The new building will adjoin the old one, the company having owned the entire square block of property since its organization. It will cost $250,000 without the machinery. According to Mr. Parke the Universal company will soon be one of the largest concerns in the world producing commercial vehicles and as the business increases other additions will be made.

NEW TRUCK FROM ST. LOUIS.

Plans Completed for Production of Light Delivery Vehicles and Farm Tractors.

The Admiral Motor Company will soon begin manufacturing operations at St. Louis, Mo., it is stated, and Don E. Evans, now acting sales manager for the Alma Manufacturing Company, St. Louis, will act as general manager for the new concern, which is expected to produce an approved type of motor truck.

The vehicle will be a 1000-pound wagon. Work will be started with about a dozen men, it is said, but the force and output will soon be increased. A light farm tractor will also be manufactured. It is stated that citizens of St. Louis already have subscribed for $10,000 of preferred stock, the total capital being $60,000.

NEW LINES AND BIG BUSINESS AT CHICAGO.

FROM the viewpoint of the exhibitors the second part of the Chicago motor vehicle show was in every way complete. The number of displays was larger than in previous years and a very satisfactory business was transacted by practically all of those who participated, at least so far as wagons and trucks were concerned, but there was comparatively little realization from the extra week by those who showed else than machines. This, however, had been the experience of those who have made display in shows of two weeks' duration, and yet, from the attitude of those who deal in cars, wagons and trucks, the segregation of vehicle exhibits had been beneficial in that it permitted undivided attention to those interested in either classification.

There were in all 76 different exhibitors, but of these one showed three different makes, two showed two, and two others both electric and gasoline vehicles, which made a total of 81 different machines exhibited. Of these 24 makes were not shown at New York, and 14 showed entirely new constructions, either in the form of an addition to the line produced or a design not previously exhibited. If there was one fact more than another impressed upon the visitor it was the number of what may be termed the lighter and smaller vehicles, which have been developed with special reference to the demands of the market as experienced by the western builders. The large and heavy machines brought out the past year are comparatively few in number, and seemingly there has been a disposition by many to build what will meet the requirements of the business men who have need for comparatively fast machines.

Twelve of those who exhibited at New York were not represented at Chicago, and adding these to the exhibitors at the Windy City this makes a total of more than 90 different makers who had displays at both shows, which is about a third of the number included in the industry. So it may be said that while the aggregate of makes seen at the two shows is a minority of the makes produced in this country, so far as production is concerned these exhibitors make a very large percentage of the vehicles built in America at the present time.

In examining the power wagons one is impelled to note that there has been no disposition as a whole to depart from conventional practise. To the contrary the majority of the designers have sought to improve by development of the types that have been worked out and well tried in service. There has been and now is a belief that it is best to perfect one or more designs instead of rejecting what has been brought to a known standard of efficiency, and to depend upon consistent development through practical experience. The policy of producing but one machine has been followed by a number of the makers who did not make a showing at New York, and while it is probable that some of these will add to their line of models later on it appears that the belief that specialization is best has been very generally approved. There are makers who assume that the larger the number of sizes built the more the varying demands can be met, but as this policy necessitates increased manufacturing facilities and proportionate expense it has not met the approval of those who believe in the possibilities of specializing.

View of the Coliseum Main Floor During the Commercial Vehicle Show at Chicago.

While the New York show was especially interesting from the number of developments, there being approximately 40 new vehicles displayed there, but comparatively little was seen at Chicago that was not shown at the Metropolis. For instance, the only new worm driven vehicle brought out was the 3000-pound Diamond T delivery wagon, and aside from the use of the Wayne gearless differential in the Ideal wagons all else was to conventional design and practise. In fact one of the surprises was that there were so few really new constructions displayed.

While eight different vehicles are built in Chicago, all of the makers appeared to believe that it would be best to reserve their exploitation for the West, instead of the East, and while not one of these was

shown at New York all made an admirable display at the Coliseum. The reason for this apparent indifference may be the fact that the manufacturers regard the possibilities of the West with greater favor than the East, a supposition borne out by the character of the exhibitions made.

The Adams Bros. Company, Findlay, O., showed a new two-ton wagon, this being the largest size this company has yet built. It does not differ materially from the smaller machines in general design, and is built entirely by the makers. The motor is a four-cylinder, water-cooled, L head type with the cylinders cast en bloc. The bore is 3.875 inches and the stroke five inches, giving a rating of 24 horsepower. The valves are at the right side of the motor. The crankcase is of aluminum and so constructed that the lower section, containing the oil reservoir, may be removed without loosening the main bearings. The motor is cooled by a centrifugal pump and a vertical tube radiator, the air being drawn through the radiator that is back of the engine and expelled from beneath the hood by the fan-bladed flywheel. The lubrication is by splash in a constant level of oil maintained by a gear driven pump.

A Corner of the Chicago Truck Show from in Front of the Adams Exhibit.

The ignition is a dual system, with high-tension magneto. The clutch is a multiple disc type and the transmission gearset is a selective sliding gear type having three forward speeds and reverse. The gearset case and the jackshaft housing are assembled as a unit and the jackshaft is mounted in the hangers, which also carry the front ends of the rear springs. The drive is by side chains.

The showing of Avery vehicles, made by the Avery Company, Peoria, Ill., was a one-ton wagon known as type C, in which the driver is seated back of the motor, and two, three and five-ton sizes of type B, in which the motor is under the footboards. The type A machines are with the driver's seat and control members beside the motor, these now being made in the three-ton size only. The motor of the one-ton wagon is cast en bloc with bore of 4.125 and stroke of 5.25 inches. The engine used in the two-ton wagon and three-ton truck has cylinders cast separately, with bore of 4.75 and stroke of five inches. The motor of the five-ton truck has cylinders cast in pairs with bore of 4.75 inches and stroke of 6.75 inches.

The Clark Delivery Wagon Company, Chicago, Ill., has discontinued the use of the double-opposed cylinder motor and all models are now equipped with four-cylinder engines having bore of 3.75 inches and stroke of five inches. The transmission gearset is selective, with three forward speeds and reverse, and by the use of jaw clutches the gears are constantly in mesh. These machines are built with the driver's seat behind or above the motor.

The Diamond T Motor Car Company, Chicago, Ill., displayed a 3000-pound wagon that has a motor with bore of 4.125 and stroke of 5.25 inches, the cylinders cast en bloc, and the clutch and gearset are assembled with the power plant. The ignition is by a high-tension magneto and a fixed spark. The drive is by worm. The company makes a machine of three tons capacity with a motor having bore of five inches and stroke of 5.5 inches, which is also worm driven. A five-ton truck, driven by chains, has the same size motor as has the three-ton machine.

The 3000 and 6000-pound machines built by the Four Wheel Auto Company, Clintonville, Wis., were shown for the first time. These vehicles have not been changed since they were first placed in the market, but they were entirely new to the visitors. This design drives all four wheels by shafts and bevel gears, the forward wheel driving shafts being fitted with universal joints that give steering control by conventional means.

The Harder Auto-Truck Company, Chicago, Ill., showed for the first time a 2000-pound delivery wagon that has a four-cylinder motor with bore and stroke of four inches, a gearset giving three forward speeds and reverse, and driving by side chains. The radiator is mounted on springs and is designed to swing to give access to the motor. There is an auxiliary spring mounted at the rear. The wheelbase is 112 inches. The wheels are fitted with 36 by four-inch solid tires.

The Harvey Motor Truck Works, Harvey, Ill., showed for the first time the 3000-pound Harvey wagon, which has a four-cylinder, en bloc motor, with bore of 3.75 inches and stroke of 5.5 inches. The wheelbase is 130 inches. The construction throughout is conventional save the wheels, which are die cast steel, and are claimed to have unusual strength and longevity. This is the lightest machine of the four American makes to use such equipment, the other vehicles on which they are used being the Locomobile, Smith-Milwaukee and White trucks.

The Hercules 2000-pound delivery wagon was

shown by the Maxwell Motor Company, Inc., this being a product of the Flanders Manufacturing Company, Detroit, Mich. This is made in two types, with the seat behind the motor and with left side drive, and the other with the seat above the motor and right side drive. It is built of standard components, having a Continental engine, a Brown-Lipe transmission gearset, a Sheldon jackshaft, Bosch magneto and Schebler carburetor. The engine under the hood type has 130-inch wheelbase and the other 110-inch wheelbase.

The Ideal Auto Company, Fort Wayne, Ind., showed a new 4000-pound wagon known as model K, which has the same general design as other machines of this make, the Wayne gearless differential being used instead of the conventional bevel gear. The motor is a Continental en bloc, having bore of 4.125 inches and stroke of 5.25 inches, rated at 35 horsepower.

The Thomas B. Jeffery Company, Kenosha, Wis., displayed three machines, the one being an adaptation of the pleasure vehicle chassis with a delivery wagon body, having a capacity of 1000 pounds. The others are one and two-ton wagons, the larger having an electric starter. The motor is the same for all three machines, having four cylinders and 4.5-inch bore and five-inch stroke.

The Chicago Pneumatic Tool Company, Chicago, Ill., showed the 2000-pound model D Little Giant delivery wagon that was developed early in 1912 and is continued without change. This machine has a double-opposed motor under the forward section of the body, and a planetary transmission. The wheelbase is 91 inches. Another type of the same capacity has 110-inch wheelbase and a selective type of gearset with three forward speeds and reverse. The two-ton model has the same wheelbase and a four-cylinder motor.

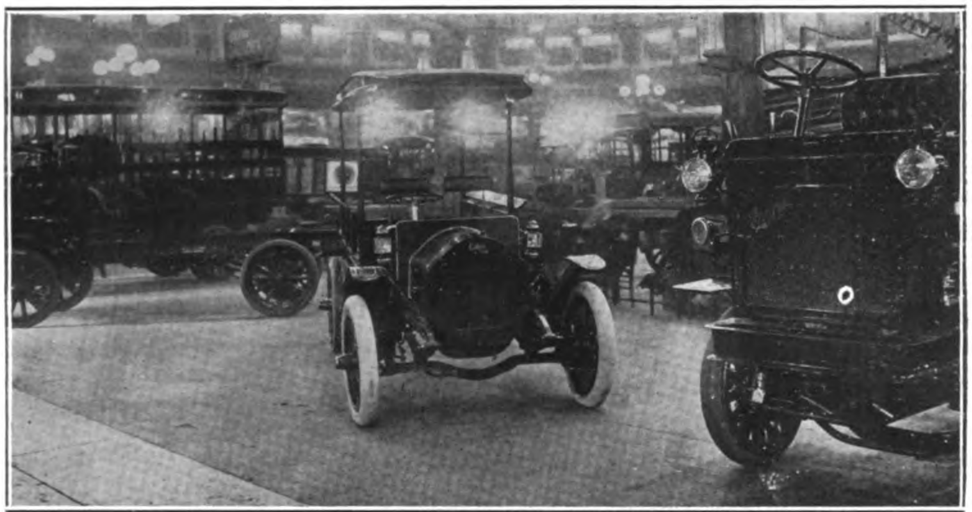
The Moon Motor Car Company, St. Louis, Mo., builds two machines, the one of 1000 and the other of 3000 pounds capacity, the latter being shown. This is equipped with a four-cylinder, water-cooled, en bloc motor of 35 horsepower and the drive is through a gearset giving three forward speeds and reverse to a jackshaft and thence by side chains.

Menominee delivery wagons of 1500, 2000 and 3000 pounds capacity, were exhibited by D. F. Poyer & Co., Menominee, Mich., and were seen for the first time at a show. The feature of these machines is the gear reduction and the straight line drive. The power plant is a unit type, and at the rear of the gearset case on the main shaft is mounted a pinion that meshes with a gear below it, which in turns drives the driving shaft, which is suspended so low that there is no inclination whatever when the chassis is under load.

The Mogul Motor Truck Company, Inc., Chicago, Ill., which last year built two, four and six-ton sizes, has for 1913 added three and five-ton machines. The L head en bloc motor of the two-ton chassis has a bore of 4.125 inches and stroke of 5.25 inches. A selective gearset is used with this construction. The three and four-ton chassis have motors with bore of five inches and stroke of 5.75 inches, and are equipped with progressive gearsets. The five and six-ton chassis have motors with bore of 5.25 inches and stroke of 5.75 inches and have progressive gearsets. On the three largest sizes dual ignition is used.

The Moore 1600-pound delivery wagon, built by the Palmer-Moore Company, Syracuse, N. Y., exhibited at the show, is fitted with a three-cylinder, air-cooled, two-cycle motor, which has variable ports and for which great efficiency is claimed. The motor is fitted with a fan-bladed flywheel, which effectually cools it. Another feature is a planetary driving system in which when one speed is set the others are automatically released.

The Old Reliable Motor Truck Company, Chicago, Ill., made display of the new three-ton truck, which has a four-cylinder, T head motor with bore of 4.25 inches and stroke of five inches. The design follows the five-ton machine, but its wheelbase is 120 inches.



A Glimpse of the Coliseum Main Floor from the Gramm Stand.

No change has been made in the Commerce, Sampson and United States wagons and trucks, while the Walker electric design remains the same. The Urban electric vehicles, built by the Kentucky Wagon Manufacturing Company, are conventional in design and the Buffalo Electric Vehicle Company is producing a 1500-pound wagon that is driven by shaft direct from the motor to the differential in the floating rear axle.

Not a little attention was directed by the builders of large machines to special bodies and devices for facilitating loading and unloading, and of these the majority were seen at New York. Several bodies were fitted with rollers for the handling of lumber, and there were numerous machines equipped with dumping bodies, these being adapted for more general service, especially for construction work. Power and manually operated hoists were very frequently used

and the majority of the former type were, because of their weight, seen on the heavy machines.

The bodies built for different classes of work, that is, for specific purposes, were exceedingly numerous, and some of these were admirable specimens of wood working and finishing. The delivery wagons as a rule were designed with keen realization of the possibilities of appearance as well as utility, and while intended for show purposes were practically all to be delivered as quickly as possible following the exhibition.

The show of accessories, supplies, equipment, etc., was large and complete, no less than 140 different firms being represented during the week.

GRAMMS IN THE PHILIPPINES.

One Concern Operates Fleet of Twenty with Satisfactory Results Despite Road Conditions.

Eight Gramm trucks recently left the plant of the Gramm Motor Truck Company, Lima, O., on journeys which will take them more than half way around the globe. Six of the vehicles were consigned to a contracting firm at Manila, Philippine Islands, and the remaining two go to Australian customers. The Manila shipment left the United States from San Francisco, while the other went from New York City.

The Gramm company has built up a good trade for its trucks in Manila, one firm now operating a fleet of more than 20. The vehicles are giving excellent satisfaction in transporting building materials and supplies, as well as regular merchandise over the type of roads to be found on the Island of Luzon.

BUYS TEN ADAMS TRUCKS.

Newark Gas Company Files Large Repeat Order After Extended Trial in Service.

The Public Service Gas Company of Newark, N. J., has placed a large repeat order with the Adams Bros. Company, Findlay, O., for 10 one-ton Adams trucks which were especially designed for the Public Service Gas Company's use. While the chassis are of standard type, the bodies are with a view to facilitating the handling of long lengths of pipe.

The purchase of the Adams trucks was the result of two years of testing by the gas company, which furnished data of extreme importance to prospective motor truck users, owing to the fact that the company not only kept an accurate record of the work done by each vehicle and the cost of operation, but was able to detail special men to devote their attention to the subject and who were trained engineers. In giving its order the Newark company places its seal of approval on the motor driven truck, both from the standpoint of economy and efficiency. It has proved the economy of the mechanical transport despite the fact that it writes off a depreciation of 50 per cent. a year on all motor vehicles.

KISSEL IN MOVING WORK.

Saves Householder Substantial Sum, Besides Eliminates Necessity for Repeated Handling.

A three-ton KisselKar truck, made by the Kissel Motor Car Company, Hartford, Wis., and owned by an express and teaming company of Chicago, recently transported a 5500-pound load of household effects from 1549 Northwestern avenue, Chicago, to 35th and Vliet street, Milwaukee, Wis., and returned home in the actual round trip running time of 36 hours. The trip was nearly 100 miles over rough and snow blocked roads and the truck proved itself not a mere competitor and successor of the horse, but a new element in transportation.

It was asserted that the trip was undertaken as a measure of economy and the owner of the goods was saved between $40 and $50. Had the goods been shipped in the usual way, the owner calculates he would have had to meet the following expenses: Crating, loading and hauling the goods to railroad terminal, freight charges to Milwaukee, unloading and haulage in Milwaukee and uncrating at destination. In using the truck the goods were handled but once in loading and once in unloading, and did not require expert packing in material or men.

PERU SECURES ANOTHER CONCERN.

Will H. Brown Instrumental in Locating Accessory Manufacturer in That City.

The Crum-Wiley Manufacturing Company, which has been enjoying a great increase of business the past year, has been induced to locate at Peru, Ind., through the efforts of Will H. Brown and the directors of his company, the Brown Commercial Car Company, Peru, Ind. It will manufacture all automobile accessories made in brass, its specialty being grease cups and other small parts used in the building of motor vehicles.

Besides Mr. Brown the directors of the new concern are the following: President E. L. Crum, Vice President Max Krauss, Secretary-Treasurer S. A. Shesler and J. R. Woodring. The company was formerly located at Decatur, Ill., but was moved to Peru when that city offered a factory site and the citizens purchased stock. A new fireproof building of brick, steel and glass will be erected and the plant will be in operation in a few weeks. In addition to the Brown Commercial Car Company, of which he is president, Mr. Brown is connected with the Peru Castings & Machine Company, which does all the foundry work for the Brown company.

Grand Rapids Buys White—Grand Rapids, Mich., has purchased a White hose and chemical wagon, made by the White Company, Cleveland, O., and it is proposed that other additions of a similar nature will be made in the near future.

LEARNING COST FROM ACTUAL SERVICE.

Staples Coal Company, Boston, Mass., Operates Gasoline Trucks for Long Hauls and Electric Carts Against Horse Work to Determine Transportation Economy.

THE transportation department of a coal dealer often represents a large sum, and with concerns doing a business of considerable proportions the investment represented by the necessary equipment is frequently no small part of the entire capitalization. The delivery of the coal is necessary with a very large part of the total tonnage sold, for comparatively few customers will haul their fuel, it being generally believed that this can be done cheaper by the dealers with special facilities. Frequently consumers will place orders of such size that daily cartage is necessary, based on the lowest price quoted for a specified quality, and sometimes contracts are based on bids submitted by the dealers in competition, but aside from these the sales are usually made with stated charges for delivery in zones of about a mile each from the yard added to the established yard prices. Custom has fixed the delivery charge at approximately 25 cents a mile a ton for all distances up to four miles, and that is about the distance that an average dealer will expect to attract patronage, because he will enter into competition with other firms having prices similarly based, making delivery under conditions assumedly under like circumstances and conditions.

This may be applied generally, and it can be stated that this restriction of patronage by delivery charges and competition is probably the average experience, but it is also a fact that concerns of large proportions having contracts and the like will require haulage considerably beyond the distances customarily regarded as the delivery limits. Though this volume of business may not be sufficient to justify stimulating, there may be many reasons why it should not be neglected, and many firms make deliveries comparatively long distances from the yards.

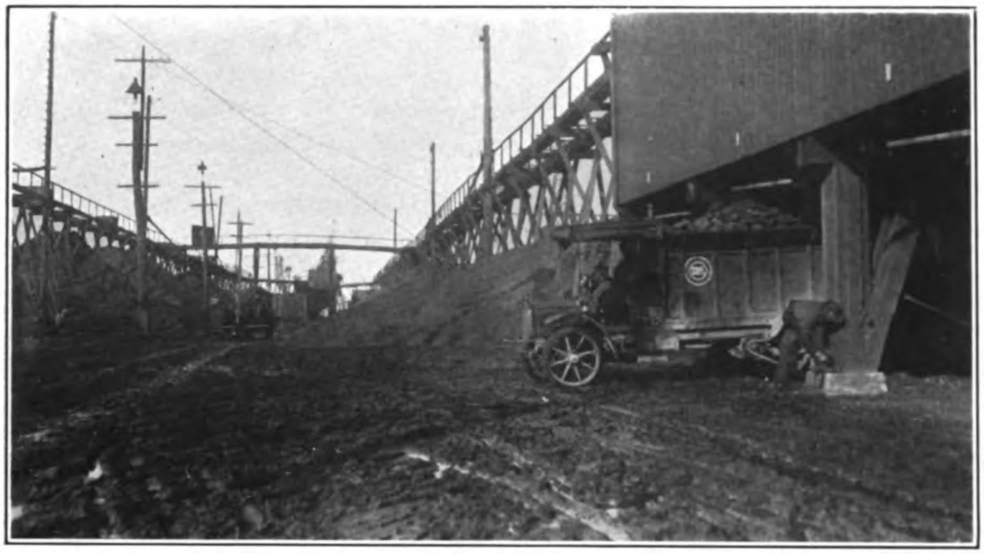
While it is certain enough that the charges made for delivery have been made by custom rather than by any definite knowledge of the actual cost, and it is probable that most coal dealers believe that they have to consider the average rather than the specific expense, it is fair to assume that whatever difference there was between cost and delivery charge when rates were established have been materially reduced, if not wiped out, by the increased expense, provided that this item was not considered in the general raising of yard prices. While no statement has ever been made as to this detail, it is a fact that the delivery charge has been maintained without regard to the variance in coal cost.

It is not possible to estimate with accuracy what a delivery equipment will accomplish. In cities like Boston a single horse may be depended upon to haul or handle from 5.5 to six tons of coal a day, averaged through the year, and it is not improbable that it will be nearer the lower than the higher figure. In smaller cities, where the hauls would average shorter distances and the customers within a relatively smaller area, it is possible that the average delivery made by a single horse under favorable street and topographical conditions might run as high as seven tons, but it would be far from conservatism to accept that figure. Considering haulage as a whole even six tons would appear to be more than a reasonable average standard.

White Truck Leaving Summer Street Yard After Weighing for a Long Trip, with the Following Horse Cart Starting on a Short Haul.

The average daily mileage of a horse may be placed at 15, though in some service this may be exceeded. The estimate ranges from 14 to 16, and considering humane working of animals and conserving their usefulness and value the figure stated is reasonable. Where a delivery service is of considerable size it is usually believed to be prudent to have extra horses, and one spare animal for every 10 is not an injudicious ratio when constant and undiminished work is necessary.

Reference has been made to the work in tonnage moved and miles travelled because they are practically



Loading the White Truck Equipped with Dumping Body at the Anthracite Coal Pocket, the Equipment Having the Advantage of Quick Loading and Unloading.

the only data to be depended upon, for costs will differ with conditions and administration. But this gives a foundation of work performed and on which cost may be fairly approximated. The delivery may be one or more long hauls or numerous short hauls, and by this standard the work capacity of any number of animals may be approximated. But while this standard will not be exceeded save during exceptional demands, it follows that when it is not realized there is not only loss, but the cost of the delivery made has been increased.

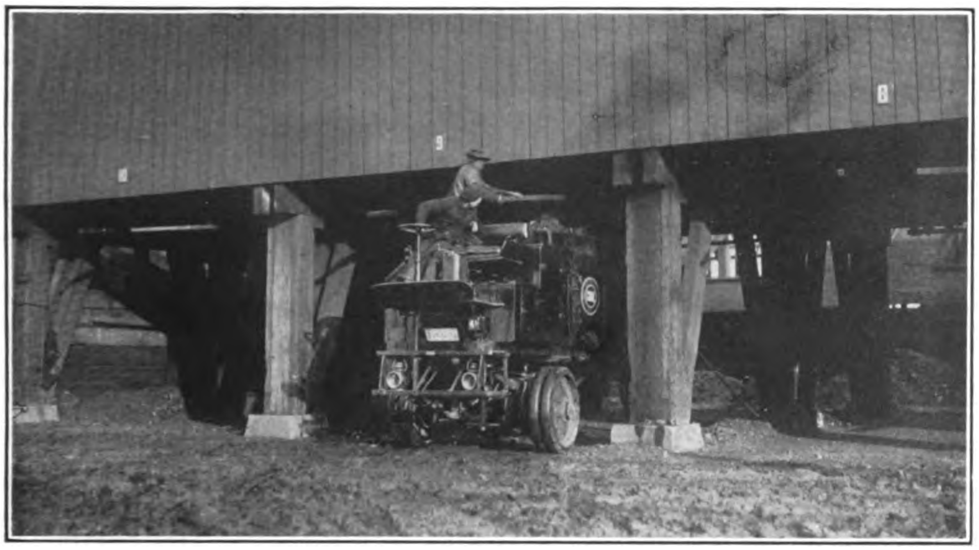
The statements with reference to delivery cost and work capacity of horses has been made to demonstrate that coal haulage is not based on actual figures and comparatively few concerns, even those having splendid accounting systems, can show that operating cost is the actual basis of delivery charges. This being so, it is evident that conclusions made as to delivery operating expenses must be founded on observation, or experience, or personal judgment of what constitutes efficiency and economy.

There are firms that seek to learn facts systematically and to determine from record of their own business just what can be accomplished with their equipment, methods and administration, and where this character of research can be undertaken it is certain enough that it will be productive of positive and practical results. In some instances a firm will investigate the facilities and work of others engaged in the same business and from the data collected establish a system that will be adapted from what appears to be the most productive of results when the conditions are regarded from differing viewpoints. This appears to be the disposition of numerous concerns that have large equipment and which, while regarding economy as absolutely essential, do not feel justified in making a change involving heavy expenditures without positive assurance that the estimated saving can be made.

In Boston a considerable number of coal firms have begun the use of motor trucks in what may be considered experimental work, and while none has disposed of all its animals and is now dependent upon machines, it may be said that the prevailing opinion is that for short hauls and with the conditions obtaining the animals are the more economical. The service of each firm differs, and though there may be practically the same delivery area it is certain that the expenses of no two are alike. This being so the practical determination of the relative cost can only be ascertained by working both motor and animal equipment. In comparative service it is essential that both types of vehicles be used with the same judgment, for it is apparent that unless the average efficiency is realized with either, at a normal expense and for a sufficient period to learn the fixed charges that should be included, the information will be of little value.

The Staples Coal Company, which has executive offices at 40 Central street and yards in Albany street, in Summer street at South Boston and at East Boston, has had a comparative service for about 18 months, and has during that time used both gasoline and elec-

Delivering a Five-Ton Load of Anthracite Coal at the Massachusetts State House, the Crew Making Short Work with a Sidewalk Manhole to the Fuel Bin.



Taking on a Five-Ton Load at the Anthracite Coal Pocket at the Summer Street Yard for an Eldridge Front Drive Electric Cart Used for Short Hauls.

tric machines. Originally the company had about 175 horses divided between the three yards, and after consideration of the utility of motor trucks three five-ton gasoline chassis were purchased, these being a White, a Peerless and a Mack. These were fitted with dumping bodies. While the desire was to learn the possibilities of the machines for all forms of haulage and to thoroughly test them, it was not believed to be economical to work these constantly on short hauls.

By this is meant that the efficiency of horses is assumed, if not definitely known, and the purpose was to ascertain the utility of the trucks by using them on practically the same haulage as the animals. This would demonstrate the economies of the machines with reference to time and labor, and with the record completed with definite cost of both animal and motor haulage, which could be ascertained later on, it was expected to determine facts with exactness. The company has large plants and excellent facilities for handling coal. The greater part of the anthracite fuel handled is brought from the barges and vessels by elevators and carried on elevated conveyors to bins or pockets, from which the carts and trucks are loaded by gravity. Much of the bituminous coal, however, is piled beneath the conveyors and this may be loaded with machines or by manual labor, the manner of loading depending somewhat upon the size of the piles and the conditions.

Practically all of the carts and the trucks are fitted with dumping bodies, so that there is the same relative economy with either for loading or unloading, and while it may be possible with such change of facilities as careful judgment would dictate that time could be saved for the trucks (assuming that there could not be similar saving for horses), it will be understood that the working of the combination equipment affords actual knowledge of what may be accomplished by superior speed and somewhat greater capacity.

The Staples Coal Company's distribution is throughout Boston and the suburbs, but from the location of the yards in different sections of the city the haulage from each is minimized as compared with what might be required were there but one yard. The trucks are worked from the South Boston yard and with them are in service horses that are driven an average of 16 miles daily, and haul four tons as a load for a team of two under normal conditions.

The trucks are garaged at the yard and are given the ordinary care and attention that is necessary by the drivers, but when a condition is known that requires specific knowledge and mechanical skill the machines are sent to the service stations of the makers, or are repaired at the garage by mechanics sent from the service stations when special facilities are not required in the work. Were the number of machines sufficient to justify it would no doubt be more profitable and economical to maintain a regular garage organization with a repair shop and machine tool equipment. But against this must be placed the expert knowledge and the resources of the service stations. But this does not appear in the bald financial statement.

In July of last year the company took delivery of

Eldridge Five-Ton Front Drive Cart Equipped with Dumping Body Loaded with Soft Coal—This Machine Is Used Generally for Work Ordinarily Done with Horses.

the first of three Eldridge front-drive electric carts, these being of five tons capacity each. These machines are built with a forebody fitted with wheels made under the Couple-Gear patent, the motive power being two three horsepower motors carried on the ends of the axle stubs, driven by energy from a battery located under the seat. The construction is heavy throughout and is intended to endure a long period under all conditions of use. There is practically no mechanism save what is contained in the wheels, and the motors are mounted horizontally on the axles so that the pinions on the ends of the armature shafts engage with racks in the edges of the heavy steel discs that carry the wheel rims and tires. The inner disc has a large bearing on the axle and supports the weight of the forebody and a part of the load.

The wheel stubs of the front axles are mounted in yokes on pivots and the cart is steered by the front wheels, the shaft of the steering gear being vertical, a pinion at the lower end meshing with a sector, and the upper end being surmounted by the hand wheel. The battery is located under the seat and the controller case is directly in front of it, there being a small removable lever on top of the housing. The forebody has spring suspension, but the cart construction, that is rigidly coupled to it, is carried on a dead axle, exactly as all carts, with large wheels shod with steel tires. These machines have been used by a number of coal companies in Boston and vicinity for haulage within a limited radius.

The maker claims for these machines that they can be driven from 25 to 30 miles on a single battery charge and on level, hard roads, and that they are most economical when worked on hauls not exceeding five miles. Although they have a speed of six miles an hour maximum, they are seldom driven faster than five miles. The expense estimated by the maker is $8.16 a day when kept at the garage of the owner, and $9.53 when stored at a public service station. This expense includes a renewal of a battery annually and one new set of rubber tires each year, and depreciation of 10 per cent. Solid rubber shoes of the dual type are used on the traction wheels, and it is maintained that these will give the estimated daily mileage for 300 working days a year. Where the work is such that greater capacity is desired this can be obtained by exchange of batteries, the removal and replacement requiring but little time or labor with satisfactory equipment.

The keeping of the gasoline machines in the company's garage is an economy as compared with the garaging of the three electric carts at the Atlantic Avenue Electric Garage, because of the somewhat greater cost this entails, and the use of energy going to and returning from the yard at the conclusion of each day's work. It is a fair assumption that this adds not less than three miles to the total required for work, which will mean at least 900 miles a year that is absolutely unproductive. This lost mileage is usually made with the carts unloaded, but it is a considerable item under any circumstances. As two of the principal costs of operation are for tires and batteries renewed, it will be seen that unless this matter of garaging is carefully considered its importance in cost determination is not fully realized.

The two electric carts last delivered were placed in service in September, and the three have been used practically six months. Though occasionally utilized for longer hauls the machines have been worked in closer competition with the horses, and basing conclusions on the information already possessed it is maintained that animals have apparently proven the more economical for hauls up to 2.5 miles, where the traffic is congested and the speed of the motor carts is practically limited by the movements of the other vehicles. The truck and motor cart delivery service must encounter this traffic and it is governed by the traffic regulations, which are decidedly exacting during the business hours of the day.

The summary of the results accomplished by the machines, both trucks and carts, during a period of six months is decidedly interesting. The loads for these vehicles are five tons, and no divided orders are sent out in them. Both anthracite and soft coal are hauled, and often it is possible to unload by dumping. The mileage of the electrics for the time stated was 3130, and for the gasoline trucks 13,729, but the average haul of the electrics has been 3.94 miles to a trip and of the trucks 8.24 miles. According to the statistics kept by the company the electrics will give approximately 20 miles on a single battery charge, which is about 6000 miles for the year, and is about 25 per cent. more than could be expected of a pair of horses, to say nothing of the 25 per cent. greater load carried.

Considering the greatest efficiency of the horse up to 2.5 miles a haul, it will be seen that the electric carts have made an average of 63.44 per cent. more than that standard, although the average mileage of the animals is not stated. The gasoline trucks have had an average haul of 8.24 miles, which is more than half the stated mileage for a day for horses, and should represent a decided economy when contrasted with the economic haulage distance for the horse as established by the company. The truck is rated as the equal of six horses, which means one five-ton machine can do work that would require three animal carts of four tons capacity, at least for the character of haulage for which this company uses its gasoline vehicles.

Work of the six machines for the six months is recorded as 1667 separate jobs, and with a total of 16,589 miles this shows the average mileage a trip to be 10.11 plus, and an average haul of 5.06 miles, although these figures do not agree with the individual averages of the two types of machines. The statement is made that the motor trucks and carts take the place of 35 horses, the animals in service being reduced in number to 140, and this has also caused the withdrawal of approximately 17 carts, for these cannot now be used, though it is possible that they might be practically utilized as trailers. The company has not as yet considered tractors or trailers, and one reason that would probably militate against such method of haulage is the heavy and slow traffic and the necessity of having

sufficient room for handling them. From the viewpoint of the coal dealer the tractor is not an attractive proposition, although there is no doubt of the economy of the equipment were the conditions such that it could be used.

Within a short time the company ordered the second White truck and when this is delivered it will use the two White and the Peerless machines. The intention is to continue the equipment now used until a sufficient period has elapsed to determine the exact data required, and then to make such changes as will appear advisable to be most economical with reference to ratio of type of vehicle. The gasoline trucks have been worked practically through two winters and the electric through one, and with the information deduced from the records kept it is not improbable that another year's experience will bring about considerable changes. There is no question, however, that the practical use of the equipment will be a decided benefit, for the knowledge obtaining from experience will mean a very full measure of economy.

STUDEBAKER ONE-TON TRUCK.

New Worm-Driven Delivery Wagon That Has Many Novel Features of Design.

The one-ton electric delivery wagon which was shown for the first time at the New York show by the Studebaker Corporation, Detroit, Mich., is noticeable from the fact that it is direct driven by a worm and gear wheel, but it is a very interesting design from many other points of view. The designer has departed from conventional practise and has mounted the motor in a very novel manner. He has suspended the battery so that it is claimed to be very free from the influence of road shock.

The motor is installed in a cradle formed from the two radius rod members, which extend from the ends of the housing of the full floating rear axle and are secured to a centre member that is movable on a transverse pivot carried in a frame cross member. While the drive is through the radius rods the relation of the motor, its shaft and the rear axle is never changed. The Wagner motor is so mounted that by removing two bolts it may be dropped, and by removing four more bolts the armature can be taken from the housing. The rear axle has a pressed steel housing and the shafts are fitted with Timken bearings. The worm gear is forged integral with the drive shaft and the shaft is carried on annular ball bearings and is fitted with two thrust ball bearings. The axle shafts are constructed so that they clutch the inner and outer flanges of the wheel hubs. The frame is a pressed steel channel section five inches width and two inches depth. This is mounted on semi-elliptic springs 42 by 2.5 inches forward and 50 by three inches rear, and the forward ends of the rear springs are mounted on the battery cradle, which is claimed to bring half the weight of the battery on the springs. The front axle is a steel drop forged I section. The battery cradle is mounted under the frame and the compartment is housed with agasote, which is moisture proof and affords a very even temperature. The floor is hard wood and drained. The battery crates are held by a bar that is secured by an eccentric locking device. The cradle is designed to use different types, sizes and makes of battery without change. The power wiring is protected by a pressed steel housing. The controller is operated by a lever centrally located in a U shaped slot, the base of the U being neutral and the four forward speeds and the three reverse being obtained by forward movements of the lever in the left and right sides of the slot respectively. The service brake is operated by a pedal and the emergency brake by a lever beside the control lever. As the emergency brake lever is operated it automatically throws the control lever to neutral. The switch key cannot be applied with the control lever in either the forward or reverse slots. The brakes are external contracting on drums on the rear wheels. The steering gear is a worm and gear type. The charging receptacle is placed in a compartment in the base of the dash, reached from the front, and there is a switch that automatically disconnects the charging circuit when the maximum of charge has been reached, and this maximum charge can be varied as desired.

SAURERS FOR RUSSIAN ARMY.

Recent Purchase Includes Travelling Repair Shop for Work on Aeroplanes.

The International Motor Company, New York City, announces that the Russian government has purchased a number of Saurer trucks, made by that company. Included in the number is an interesting type of army truck known as the aeroplane repair vehicle. This is a standard five-ton Saurer chassis, equipped with 37 horsepower motor, chain drive and solid tire equipment. The maximum speed is 15 miles an hour.

The body platform has sufficient space for a machine shop equipment consisting of a five-kilowatt dynamo and engine lathe driven by a small electric motor, shaper, band saw, drill press, portable anvil with block, portable forge, carpenter's working bench with wooden and steel vises, an acetylene welding apparatus with oxygen tank, emery grind wheel, hand drills, etc. Along parallel lines are closets for tools, etc. The total weight of this portable machine shop is 15,000 pounds.

H. J. Koehler, president of the H. J. Koehler S. G. Company, New York City, announces that he has just completed a sale of a battery of 10 Koehler commercial cars to the Public Service Gas Company of Newark, N. J. The machines are to be fitted with special bodies and will be used in different sections of New Jersey for general hauling and emergency work. It is stated that the company has had a number of electric trucks in service and that the Koehler cars are the first of the gasoline type to be installed.

ADVERTISING RATES.
Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.
Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.
Entered as second class matter, February 25, 1911, at the Post-office at Pawtucket, R. I., under the Act of March 3rd, 1879.

THE BOSTON TRUCK SHOW.

The business possibilities of the power wagon show at Boston are extremely promising, and with the unusual interest in motor trucks and wagons manifested by business men there is reason to believe that the exposition will attract many buyers. It can be accepted as a fact that there will be few attracted to the show from curiosity, and the exhibitors who do not make provision for the presence of the best of their selling forces will make serious error. A year ago, following the extreme rush of the pleasure car show, some of those having exhibits were content to leave their stands with but one person during the day, and in several instances failed to have men in charge who were capable of doing full justice to the machines. There was generally a sufficient number in attendance in the evening, but the opportunities of the day, when many were present from out of the city, were often lost.

LIMITING VEHICLE WEIGHT.

In Massachusetts a bill is pending before the legislature that limits the weight of motor vehicles and their loads to 12 tons. It is proposed in other states to enact similar restrictions. The Massachusetts bill, which is a compromise of those interested in motor trucks and the highway commission, which indorsed the measure, will possibly be adopted. If the highway commission will consult its own records it will be found that former Chairman W. H. McClintock was very emphatic in the statement that unless a vehicle was moving 15 miles an hour it did not damage the highways. If the bill is wholly with reference to bridges, it will be found that the majority of the trolley cars used on suburban routes weigh from 11 to 14 tons unloaded, and with reasonable freights several tons additional, and if the bridges are not safe there should at least be consideration of the people who ride in these cars.

Each year the Massachusetts highway commission has proposed legislation that has seemingly been directed toward limiting the possible uses of practical vehicles for highway haulage, and generally with the claim that the roads were wearing under the traffic. The logic of such a declaration seems without foundation from the fact that highway transportation must increase, and as it is greatest on the main and improved thoroughfares and least on those not in good condition, these roads must be worn. As they wear they must be maintained. According to the figures collated by the commission the business wagons are increasing in numbers very rapidly. The towns benefit through such use. If the highway commission were the ally of railroad corporations that would control all haulage it could not direct its influence to a better purpose than it now does.

DRIVING TRUCKS WITHOUT LOADS.

Men of experience know that more actual wear results from driving a motor truck unloaded than when loaded, and this from the fact that the heavy springs have absolutely no resiliency when not under pressure and might just as well be dispensed with so far as their usefulness is concerned. That is to say, that if the construction were without springs there would be no material difference in effect upon the vehicle so long as it were driven unloaded, and in general use this is 50 per cent. of the time at least. It is evident that were the springs to have the same effect when the vehicle is unloaded as when loaded there would be a very large reduction of the wear resultant from excessive vibration, but this is not possible with designs of the present day.

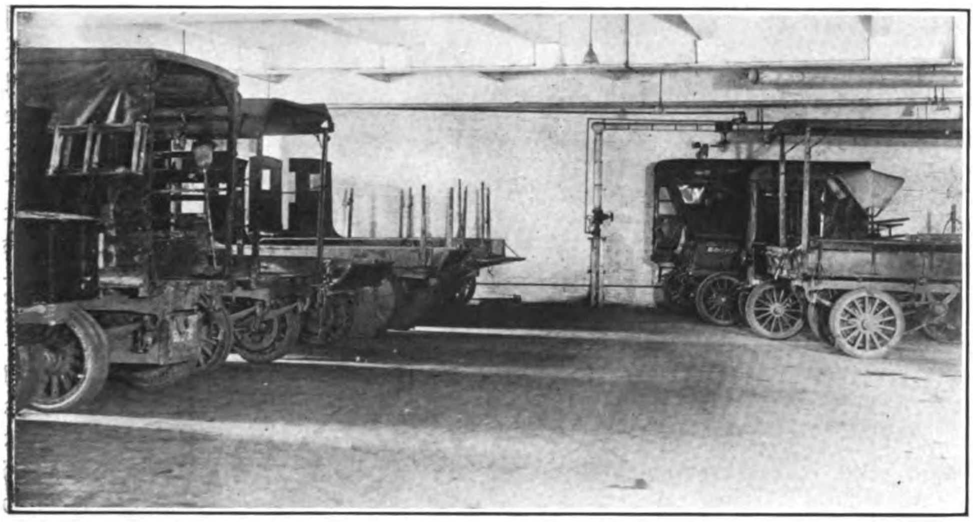
The only remedy then is to minimize the speed when driven without load, for the assumption of practically all drivers is that this period of use is when a machine can be operated to its maximum speed. This may appear to be a paradoxical statement, for it will be maintained by many that it is unwise to drive as rapidly when loaded as unloaded, but the real secret of truck efficiency is not speed, but in keeping it moving. Uniformity of pace and expedition in handling the freights carried are two extremely important factors in economical motor wagon operation, and an average of even six miles an hour for a half-day will give a very satisfactory day's work when measured by mileage.

CENTRAL STATION TRANSPORTATION.

The Motorized Service of the Rochester, N. Y., Railway & Light Company, Includes 61 Wagons, the Largest Number in Proportion to Population in Use in This Country---The Development of Four Years.

By William W. Scott.

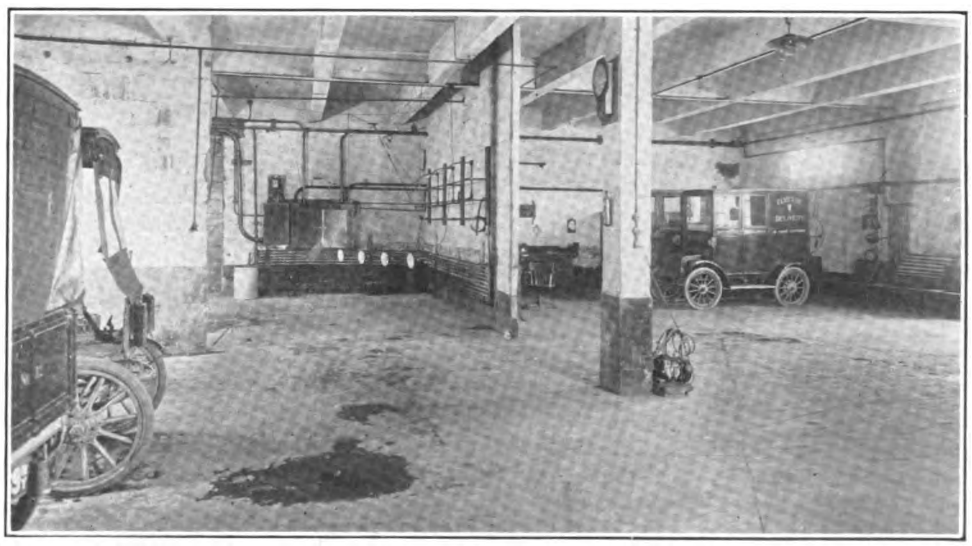
THE practicability of the use of electric vehicle equipment by central stations located in cities of moderate proportions has been established very conclusively by the experience of the Rochester Railway & Light Company, Rochester, N. Y., one of the best known and most progressive public service corporations in New York State. There may be supposition that the practical economy of the motor vehicle can be best realized by central stations in the largest cities, for theoretically in such municipalities the cost of haulage is relatively more than those of lesser size, but this assumption does not have foundation when even casual analysis is made.



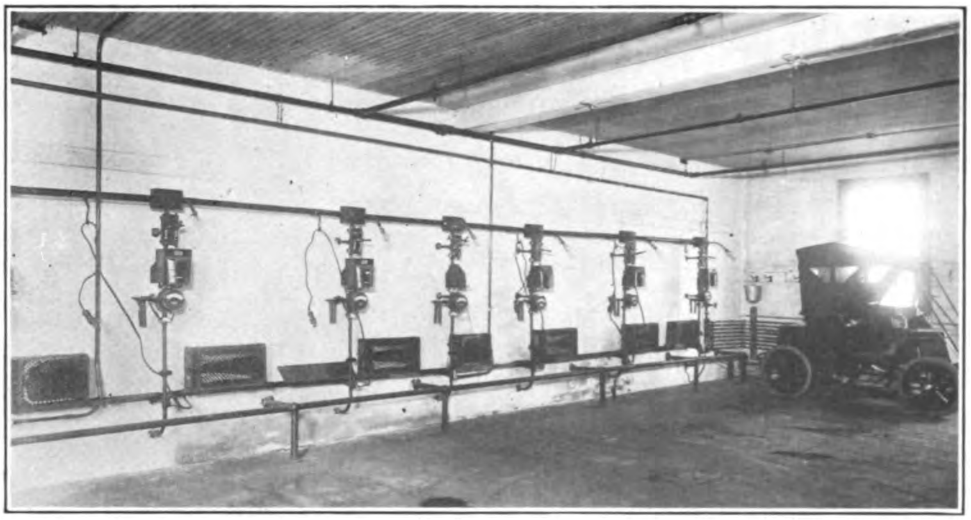
The Main Garage of the Rochester Railway & Light Company, in Which the Truck and Heavy Wagons Are Stored.

To illustrate, the transportation department of the New York Edison Company, the largest corporation of the kind in America, which serves Manhattan Island and the Bronx, is not twice as large as that of Rochester, and while the former company serves a population of perhaps 2,500,000, the residents of the area served by the Rochester company are probably less than 300,000. When one considers the areas in which the two companies operate there is probably little difference, but there is in New York the greatest concentration and in Rochester there is what might be compared with the suburban conditions of New York. Yet there is this difference, which will account for the apparently large number of machines in use in Rochester, and that is that the company generates and distributes gas for illuminating purposes and for fuel, as well as supplies electric current for lighting, heating and power, while in New York the Edison company sells electric energy only.

In other words, the gas department of the Rochester company, which covers the same territory as the electric department, necessarily requires transportation. This division is not subordinated to the other and it is promoted and developed carefully. While it is not possible to state the relative proportions of the two departments, it is obvious that the combination of the two with reference to vehicular service has necessitated the use of a much larger number than might be assumed by those who have no accurate knowledge. Incidentally it may be pointed out that the Rochester company may be paralleled so far as combination service is concerned by hundreds of companies, and the transportation requirements will be found to be analogous. Rochester may be regarded as a large



No. 2 Garage of the Rochester Railway & Light Company, Showing the Washstand Separated from the Main Floor.



No. 3 Garage of the Rochester Railway & Light Company, in Which the Runabouts and the Light Wagons Are Kept.

city in the sense that there are only about 25 cities in the United States that exceed it in population, and it may be maintained that the same experience would hardly be realized in cities of lesser size, but it will be understood that haulage economy will obtain wherever motor vehicles are used judiciously, although it is evident that there will be the greater ratio of saving as the number of machines is increased.

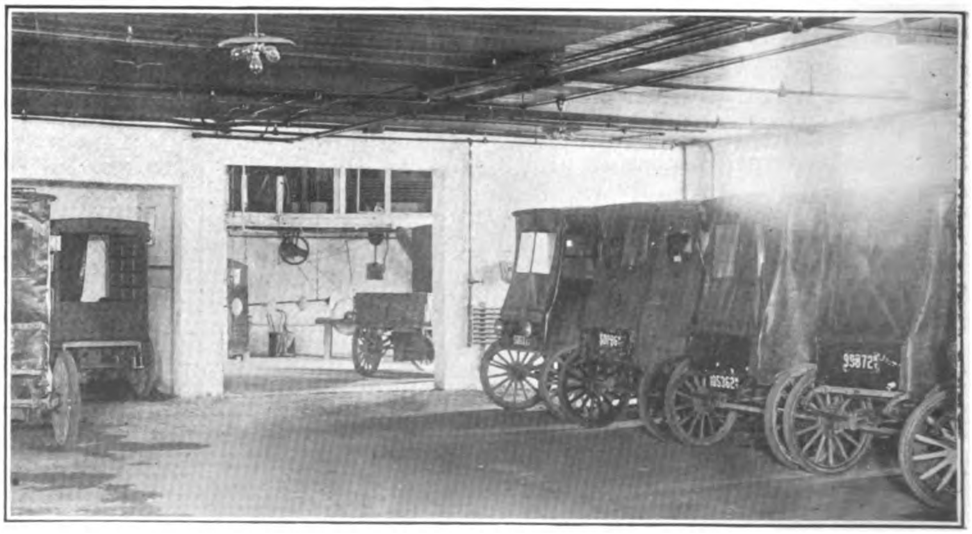
The Rochester Railway & Light Company is progressive and its property will compare favorably with that of any similar concern in the country. All construction is high class and well maintained, its equipment is modern in every respect and expansion is made with regard for future requirements. Four years ago it used 60 horses in its transportation department, and this number has been reduced to six, while the animals dispensed with have been replaced by 52 electric wagons and trucks, and nine pleasure cars, some of them small gasoline machines, are also utilized. The question will naturally arise of wherein is the saving when 54 horses have been disposed of and 52 motor wagons and several cars substituted, especially when it is known that one power wagon is believed to be the equal of at least two horses.

In answer to this it is necessary to point out that besides its animal equipment the company was compelled to hire cartage constantly, this excess service amounting to a considerable amount annually, and during the past four years the extensions of the gas and electric mains have increased the area served approximately 50 per cent. Rochester has for a number of years grown very rapidly, and the suburban and the industrial development has entailed corresponding service from the company. This expansion has largely increased the demands upon the service department, and it is not unreasonable to assume that were horses used exclusively today a much larger number would be necessary than when the first electric was installed. But as the limitations of the stables of the company had been reached, to have continued with horses would have meant the construction of additional buildings and a larger investment, as well as the utilization of land that would be expensive if acquired.

The company has three sources of electric energy, the one being the plants that are on the banks of the Genesee river and are driven by water power, the second being steam plants located practically in the centre of the city, and the third the lines by which the current from power stations on the Niagara river is transmitted about 80 miles and drawn upon as requirements may necessitate.

Contrary to the usual custom of concentration the Rochester power stations are separated and there are about a dozen of them located within a mile circle, each of which serves a certain area of the city, but all are so connected that in the event of need the service may be continued without interruption should it be necessary to continue the operation of any one for a period. The gas producing plants are quite as advantageously located.

The section in which the company gives service may be covered by a circle 15 miles in diameter, in which Briden is the most distant point of consequence, and this is about seven miles from the centre of the city. The total area is about 100 square miles. The topographical conditions are such that transportation expense cannot be regarded as excessive when contrasted with other localities.



No. 4 Garage, Used for Light Wagon Storage, Which Is Connected with the Machine Shop.

Section of the Machine Shop of the Rochester Railway & Light Company, Which Has Abundant Space and Ample Facilities.

needs of the department were realized horses were disposed of and new motor wagons and trucks purchased, so that now there are the 52 electric machines in service, as well as nine electric and gasoline pleasure cars, making a total of 61 used by the company.

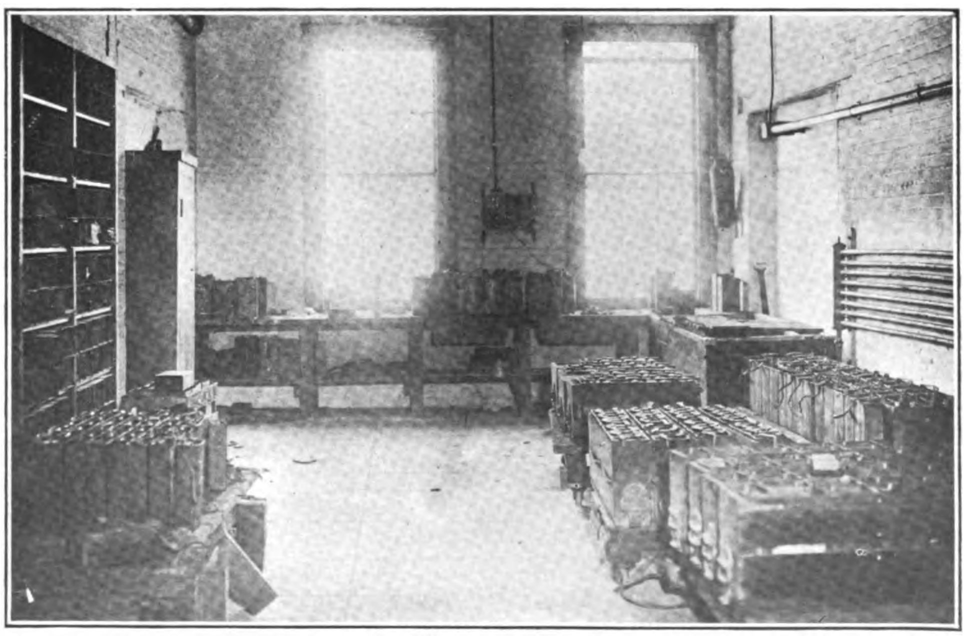
As the animals were sold and the machines were added to the service the stable buildings were remodelled and fitted to serve as garages, which necessitated the removal of partitions and fittings, the laying of cement floors and the installation of such equipment as was necessary. That this work was not done at one time and it was necessary to progressively increase the facilities did not permit of as economic an arrangement of the garage as might have been possible under other conditions, but as the needs were realized the equipment was added. As the buildings are nearly all connected and the different garages are convenient to the other departments, there is no loss of efficiency through the conditions.

As it now is the garage will afford storage for a considerable number of machines in excess of those now cared for, and the repair shop and battery room are of such capacity that they will suffice for any demand that will develop. The fact that the battery room is ample for all probable requirements for several years to come, and the repair shop will house more machines than will ever be withdrawn from service under normal conditions indicates that the buildings were fitted with careful consideration of the possibilities. There are three buildings given over to

While it was logical enough for the company to turn to the electric vehicle from the fact that it produced electric current, and it might be maintained that it would be good business judgment to operate several machines at a considerably higher cost than of horse wagons because of the generally promotive effect of such vehicles in its service, the proposition comprehended a complete translation of the transportation equipment, which could not be made on any other basis than economy.

In the determination of the proposition it was believed the company was in a favorable condition for making a gradual change because one of the stables could be utilized for the initial garage, and then the others could be adapted for general or specific purposes as the need was realized. Had there been one large stable it is probable that the problem might have been more perplexing, but the conditions favored a practical trial of the machines. Accordingly six machines were ordered and these were placed in service in June, 1909. A section of a stable was transformed into a garage and an organization was created for the systematic care and maintenance of the equipment. The company realized that it was necessary to keep the vehicles to a standard of efficiency, and that this could not be done unless there was careful oversight, and that system was imperative in insuring the productiveness of the service.

It is not necessary to go into detail of the experience of the company, but the best evidence of the satisfaction resulting is that today only six horses are used and the motor vehicles have been increased from time to time. As the



Portion of the Battery Room of the Rochester Railway & Light Company's Garage, Which Is Well Fitted for the Purposes Used.

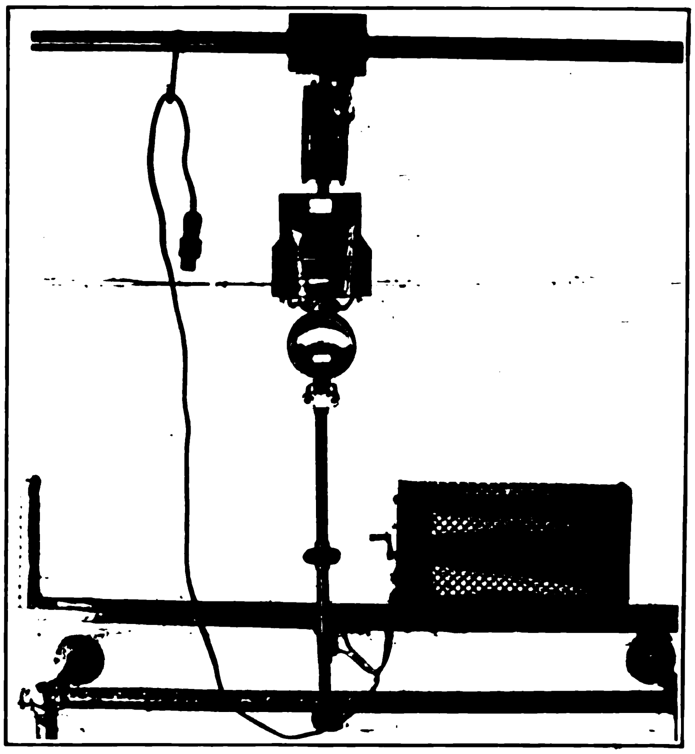
The Fleet of Electric Delivery Wagons and Trucks in Service of the Rochester Railway & Light Company.

the storage of wagons and trucks, and connected with one of these is a washroom where three vehicles can be handled at one time. In one of the garages all the pleasure cars are kept together, and the service wagons are divided according to capacity.

The blacksmith shop is a good sized section that is fitted with every tool that might be needed, and the machine shop is in a comparatively large building that has a fine machine tool equipment, including a lathe, drill press, shaper, grinder, power hack saw and a complete outfit of hand tools. There are pits in the concrete floor to facilitate work under the wagons, and ample benches and good light. The battery room is well arranged to convenience the work, and the facilities are of the best. The lighting is exceptionally good, even in the washroom, there being a variable battery of lamps that may be placed at any desired height. The buildings are well heated and the vehicles are protected against low temperatures, while the ventilation is very good.

One of the features of the garage is the charging equipment, which is installed in the three buildings in which the wagons are stored. The gravity charging is used and instead of the multiple charging panels there is a single station for each machine placed against the wall directly under the main conduit. This station consists of a tablet carrying a pilot light and a knife switch, and below this is a standard that supports a wattmeter and an ammeter, and from this there are leads to the rheostat carried on a bracket at one side of the standard, and the lead that carries the charging plug. Because of the method of charging there is no inconvenience from the use of the individual stations, and there are advantages in that minimum space is required, the cost is comparatively small, and the system can be extended as desired by the addition of such stations as are required. At the base of each station is a small iron pipe rail that protects the instruments and the rheostat and insures against damage or injury from contact.

The description given of the garage is desirable from the fact that the condition met with by the company was unusual, and yet a very satisfactory service has been made possible by the utilization of the old stable buildings. In the transportation department of the company the work of both the electric and gas divisions are handled, this service being under the direction of Frank Hellen, superintendent of gas distribution, and the supervision of the garage is by Mr. Hellen, who is assisted by Thomas W. Nash, foreman of the department. The department records so far as they relate to service are all kept at the division office, and these also show the cost of operation, maintenance and care, but the accounting is by the general office staff, for to the figures compiled must be added the fixed charges, which are not kept separately. The service and garage records are very complete and the forms have been developed from experience, so that they may be said to cover practically every condition that may arise and every probable requirement. But with their completeness the records are comparatively simple, and they are generally of such a character that they may be continued for a considerable period with very little clerical work.



One of the Individual Stations Used for Gravity Charging in the Garage of the Rochester Railway & Light Company.

Rochester, N. Y., the Largest Used by Any Central Station in America Serving a Similar Area and Population.

The electric vehicles of the transportation department are generally light, and 80 per cent. of them are of one ton or less capacity. The service is generally what can be given by machines of small capacity, that may move with reasonable speed and be economical of operation. The equipment of the company is as follows:

Capacity, Pounds	Number
700	9
750	1
1,000	24
2,000	9
4,000	4
7,000	2
10,000	3
Total	52

Of these two 700-pound wagons were made by the Baker Electric Vehicle Company, one 750-pound wagon was built by the Walker Vehicle Company, one 4000-pound wagon was produced by the Studebaker Corporation and the other 48 are General Vehicle machines. Brief examination of the sizes of the wagons will show that the company has what might be termed a light vehicle equipment, as it is not necessary to haul much of the supplies and materials used in the power stations. The work is practically all confined to construction and serving customers.

A better idea may be gained by showing the work the different types of wagons are used for. For instance, the 700 and 750-pound machines are used by the electric motor department for carrying out meters that are installed in residences and plants of different kinds, and similar machines are utilized for the distribution of new incandescent lamps and the collection of bulbs wherever these may be needed. The 1000-pound wagons are used by the electric department for taking out and locating arc lamps, for carrying material and tools for use in the line department, and for carrying meters for the gas department. The 2000 and 4000-pound wagons are used for the distribution of stoves and fittings for the gas department, one 7000-pound truck is utilized for pulling cable for the underground construction gang, and the others are worked for general purposes, there being no regular assignment for these machines. One of the 7000-pound trucks is fitted with a winch, and one of the 10,000-pound machines has similar equipment. Where very heavy work is required one of the 7000-pound trucks is used as a tractor and it hauls a body carried on two wheels that is designed to carry eight tons. This tractor has proven to be exceedingly useful and has been found to be unusually economical. The truck can haul the load under all of the conditions that have as yet been met. The trailer or body is so constructed that it may be quickly attached to the truck and in a comparatively short time the outfit may be made ready for work.

One wagon is fitted with what is known as a "house pump," and is used for pumping accumulations of water from the gas pipe, a work that is done very frequently, and another is utilized as an emergency wagon, it having such equipment as would be ordinarily useful in making temporary repair or restoration of wagons that have for the time being become inefficient through accident. Under normal conditions there is a regular assignment for each wagon and it is continued in such service unless equipped for special work. This does not apply to the heavier trucks that are used for general haulage, which are assigned from day to day. As might be assumed the mileage that is

traversed by the wagons varies considerably. Taking the month of September, 1912, as an example, three of the machines were not in use, but a record of 40 wagons showed that they were in service a total of 1084 days, and that during the month the aggregate mileage was 24,075, an average of 22 miles daily. The smallest average mileage a day for the month was 12, while the largest was 41, and these extremes were the same size so far as vehicle capacity was concerned.

Considering the mileage further it may be said that the average for the five-ton trucks will approximate 30 daily, while the lamp wagons are driven from 35 to 38 under ordinary conditions. The average of all the machines, however, is not far from 25 miles. The number of horses that would be used to do the work assigned to each wagon is difficult to estimate, but all of them will do the work of two on the basis of the daily average mileage, and some the work of three. There is, however, the elasticity that is not found with animals, and in the event of necessity the wagons can be used all of the time aside from the period required for charging, and by the exchange of batteries some of them may be in service almost constantly.

When the company had tried out the first six machines ordered and had found them in every way practical and economical the possibilities through promoting their use received serious attention, for the wagons caused a great deal of interest among the business men. The company's officers regarded the electrics with such favor that an agency contract was entered into with the General Vehicle Company and for a short time a selling campaign was conducted with moderate success, but as the promise for this business was very large, and the opportunities appeared to justify the establishment of a separate enterprise, the Empire State General Vehicle Company was organized. In this concern some of the principal stockholders of the Rochester Railway & Light Company have an interest. With this company it was possible to transact a general motor vehicle business and to exploit every line that justified attention. That is, the formation of the company made it possible to give attention to selling all makes of machines, to sell accessories and supplies, and to afford a general garage service. Until the company could be located its machines were kept at the garage of the Rochester Railway & Light Company, and its office was at the garage, but after the company was established its existence was entirely separate and apart.

There is no doubt whatever that the two-fold interest of the officers of the Rochester Railway & Light Company in electric vehicles impelled careful study of the service possible through their use, and this resulted in the application of practical methods and systematic attention and care, and, consequently, the expansion of the equipment and the garage was with reference to the possible needs of the future quite as much as to the requirements of the present.

The system of the company is especially interesting. Records minimizing clerical work and containing every desirable fact are noted. To understand these data fully it may be well to follow a vehicle through the garage from the time it is purchased, assuming it receives the regular care that is necessary as a result of service. After delivery is accepted the machine is given a number that is continued without change and by which it may be identified. These numbers are without reference to capacity and the ve-

hicles are not grouped as to size. This number is entered on a filing card that is also numbered and dated, and the heading is filled with the name of the manufacturer, from whom purchase was made, the date of the order, the style or type, the capacity by pounds, the form of body, the wheel diameter, the tire sizes, the make of battery, the number of battery cells, the battery ampere-hour capacity and the type or maker's designation. The wheels are numbered with reference to position, the right front being No. 1, the right rear No. 2, the left rear No. 3 and the left front No. 4, but each wheel is given a serial number that is continued through the service of the wheel, this being used to identify it should it be changed on a vehicle, or shifted from the one machine to another. This wheel serial number is stamped on a brass plate that is secured to the felloe of the wheel. In the card record the serial number is noted on each wheel, as will be seen from an examination of the card form. The maker's serial number of the tire on each wheel is entered on the card, but each tire is further identified by the tire serial number of the company, and the latter is used through the records, the former being merely useful when dealing with the manufacturer, should there be occasion to do so. The machine is weighed and it is then ready for charging, it being assumed that an inspection has established it in perfect operative condition.

This card is arranged for 32 entries, one for each day of the month and a total, and on it are entered each service data, showing the date use was begun and any change of battery, wheel or tire; the material cost, showing the part and the cost; the labor expense, showing the cost of work on battery, electrical element, chassis mechanism and miscellaneous; the time the machine was out of the garage, the number of miles driven, the current used in kilowatt-hours and ampere-hours and the name of the driver. The card is renewed the first of each month and this record is of the machine as it is in service, but by reference to the cards it is possible to learn of any essential fact that may be desired.

For instance, the cost of labor and material is accounted for, any change of battery, tires or wheels are shown, and the hours and miles of service and the current used, but of course this does not indicate the wages of the driver, the proportion of the fixed charges that shall be applied, and the value of the work is not noted other than in number of miles driven.

From this series of cards is each month compiled a sheet under the heading of "Cost of Auto Maintenance." This is in effect a summary made up largely from the totals shown by the cards, and it is a very interesting statement, for it permits comparison of the service and operating cost aside from the fixed charges. In making up this sheet the vehicles are grouped by capacity without reference to number, for the purpose of convenience "style" being the designation of size. The first column shows the number of days in service, the total number of miles driven, the average daily mileage, the current used in kilowatt-hours and the average kilowatt-hours a mile driven, the total cost of labor, the total cost of material, the combined totals of the cost of labor and materials, the average daily cost of labor and materials, the average cost of labor and materials a mile driven, the average cost of operating the vehicles, and the average number of days each wagon was in use.

The combination of the usual index card and the working record of the machine simplifies the clerical work and with these cards the cost summary is made up each month in the general offices. The removal of the cards does not in any way delay the continuity of the record, and the preservation of the cards is provided for by filing those of each vehicle separately.

When a wagon has been placed in service a driver is assigned to it, and the work may be of a regular character or it may be general haulage and delivery, but the record is kept on a "daily time sheet" that is identified by the number of the vehicle. Usually a sin-

gle blank will suffice for a day's work, there being seven entries possible on a sheet, these showing the date and the work in periods of time from the start to completion and the time so occupied; the nature of the work, the number of the job and the number of the account to which the work is charged. This is supplemented by remarks, if necessary, and the signature of the driver. These sheets are deposited in a box in the garage office and each morning are sent to the general office. It will be understood that the cost of haulage with reference to any work is charged against the job and this is included in the charge to the customer when the bill is made out and sent to the individual.

The machines are used generally through the day and when they are returned to the garage the drivers make report of any condition that has developed that should receive attention. Under ordinary circumstances need of adjustment or repair will be manifested from operation. The reports are received by the foreman. As the machines are brought into the garage they are washed as rapidly as this can be done and after being placed on charge are oiled and greased. In the washing, cleaning and oiling the wagons are so closely examined that any untoward condition may be discovered, and if such discovery should be made report is made to the garage foreman. Unless the condition reported is inconsequential the foreman orders an inspection of the wagon, and this necessitates an examination of the machine in detail and a statement of the work found necessary upon it. This report is turned over to the night foreman and if the work can be completed before the wagon is again needed for service it is done.

This inspection card necessitates a systematic examination of the controller, the steering gear, springs, wheels, axles, tires, wiring, brakes, motor, chains, sprockets, countershaft, battery and connections, and may include all of 54 different items and such other condition as may be found. Possibly suggestions are made in addition to the items of the report. Taking this report, the foreman notes the material needed on the reverse of the card, which order may be amplified as the work progresses, and later the name of the mechanic, the date, the number of hours of labor, the rate of wage an hour and the total charge for labor are entered. The summaries of the items are certified by the foreman. This card is a full record of the condition of the machine, the work necessary, the material required and the labor performed, as well as the cost of the labor. From these cards and the requisitions on the stock room of parts, supplies, accessories, etc., the monthly records are filled.

While this provides for the repairs that are definite in character and which will take specific material and labor, provision is made for recording the time of the workmen when engaged on work that may be regarded as general attention or is not provided for by the inspection cards. This is noted on the "daily time ticket" by the workmen, and the work may be charged to any one of six accounts specified. The number of the vehicle, the number of hours, the rate of hourly wage and the total charge is credited to battery operation and renewals, either general or specific; to repairs of mechanical parts of the chassis and to body repairs and painting; to general tire expense; to cleaning, care, charging and miscellaneous; to office expense or to repairs to garage and fixtures, and these credits are certified to by the foreman as correct with reference to the work, the account and the number of the machine. These items may be classified under the head of general operation expenses.

When a tire is received from the stockroom a file index card is filled and on this is entered the company's serial number, the number of the card, the date, the name of the manufacturer, from whom the purchase was made, the date of purchase, the style and the size.

Reverse of Battery Charging Record, Arranged for Individual Tests of Cells During Overcharge.

If the tire was received with a machine this record is made and when a change is from one wheel to another or from one wagon to another, the entry shows the number of the wheel and the number of the wagon from which it was removed and the number of the wheel and the number of the machine on which it is placed. When a repair is made an entry shows the nature of the work, the cost of labor and material, and the mileage is recorded with reference to each vehicle. If occasion requires a statement is made relative to condition, endurance, etc.

With each vehicle wheel a card record is made for an index that shows the number, the card number, the date, the name of the manufacturer, from whom purchase was made, the date of purchase, the style and size. This record is in form identical with that made for the tire so far as changing from the one vehicle to another is concerned, with the cost of the repair with reference to parts used and the labor and material. The mileage of the wheel is also kept.

The record of the battery received with each machine or purchased separately is also kept on an index card, this showing the number of the battery, the number of the card, the date when the card was filled, the name of the manufacturer, from whom purchase was made, the date of purchase, the type, number of cells and capacity. In the event of change the date of the change and the numbers of the wagons from which it was taken and installed are entered, and under the heading of repairs is noted the part used for repairing, the cost of labor and the material. The miles used, the total kilowatt-hours, the number of ampere-hours and the number of charges given are noted, so that the service of each battery may be traced, no matter how many vehicles it has been used with, and the condition is also recorded. This card is continued during the period of usefulness of the battery.

The charging record shows the number of the vehicle, the date, the make of the battery, the number of cells, the number of plates, the type, the number of trays of cells, and one form suffices for a month. The entries show the specific gravity of the battery as shown by the pilot cell when leaving the garage, and the temperature of the battery; the specific gravity and temperature on the return to the garage; the drop in specific gravity during the use of the battery; the trip and the total readings of the odometer; the time of the trip; and the record of charging shows when it was begun, the charging amperage, the time when the amperage was reduced and the condition with reference to gassing. Provision is made for three separate periods of charging. Once in two weeks, or as often as may be believed to be necessary, the battery is given an overcharge, and then each cell is tested as to specific gravity and is equalized and brought to its highest state of efficiency. In the overcharging it is necessary to test each cell no less than 18 times, the time, the temperature and amperage being noted for each test. This sheet is signed by the person supervising the charging.

The gravity system of charging is employed exclusively, and it is maintained that this affords a more accurate knowledge of the battery and each individual cell than would be possible by charging by voltage, and that it is possible to better balance the cells and have a more efficient battery. The record of each bat-

tery is kept separate and it is possible to gain more specific information from it than from the form that is customarily used with voltage charging.

The garage organization includes 12 men, that on duty days consisting of the foreman, a mechanic, a machinist, a batteryman and two helpers, and there are on duty nights a foreman, a batteryman, a mechanic, a man who waters batteries and assists in the repairing of electric vehicles, and two helpers. Besides the care of the electric wagons and runabouts there are several gasoline machines stored in the garage, and these are also given such mechanical attention as is necessary.

The Electric Vehicle Association of America's monthly meeting, held Feb. 25 at the Engineering Societies' building, 29 West 39th street, New York City, was addressed by James M. Skinner, engineer of the Philadelphia Storage Battery Company, Phliadelphia, Penn., whose subject was "The Philadelphia Thin Plate Storage Battery." Mr. Skinner is a well known battery expert and his address, aside from dealing with the products of his company and giving a great deal of valuable information, was especially interesting from the viewpoint of acid battery design, construction, maintenance and care. Following the lecture the subject was generally discussed by a considerable number.

Electric Vehicle Truck, Bought in 1904, Now Hauling Tires Across a Street from Hartford Factory to Storehouse.

Tate Electric, Ltd., is the name of a company organized to build and sell electric service wagons and pleasure cars in Canada, the directors of which are Henry Timmins, N. W. Timmins, W. Scott Hutchinson, C. E. Archibold and S. Carsley of Montreal, D. A. Dunlap and A. O. Tate of Toronto. The factory and production manager is Albert Kaltschmidt of Detroit. The company is to build a factory of two stories, having 84,000 square feet of floor space, of steel and brick, at Walkerville, which is across the river from Detroit. The executive offices will be at Montreal.

SHORTEST HAUL OF RECORD.

Electric Truck Carries Tires Across a Street at Hartford and Saves Company Money.

When the Hartford Rubber Works Company, Hartford, Conn., was an independent concern and not a division of the United States Tire Company, its officials were generally residents of that city and were naturally interested in its other industries. The Electric Vehicle Company was once one of the most prosperous concerns in Hartford, and the spirit of cooperation and promotion resulted in the purchase of an Electric Vehicle five-ton truck in 1904, which was used for all manner of transportation. The machine was for a long time worked in freight haulage and in express cartage, and the results were in every way satisfactory.

But there came a time when those directing its use believed that the electric was not as economical for general work and it was laid up for a considerable period, and then offered for sale, for in the opinion of the official of the company supervising the transportation it was somewhat antiquated, as trucks go. The storehouse of the plant is across a street from the factory and the distance from the entrance of one to the entrance of the other is perhaps a couple of hundred yards. With the utilization of the storehouse it was necessary to carry the tires, and because they are not packed each shoe must be handled individually. It was realized that this transfer was costly and economy was essential.

The old truck was thought of. It was looked over and made ready and then it was given a steady assignment running between the factory and storehouse, carrying five tons or more each trip if desired, and making about 20 round trips daily. The machine might be made to do more work, but this is all that is required of it. The five-ton loads have brought the cost of handling down very low and aside from the driver the expense of operation is small. The company makes its own current and the truck is charged every alternate night. Instead of being regarded as a relic and of doubtful value it has been found to be a very desirable property, and the means of a considerable economy. So far as appearance goes the machine is not unsightly and there are but little evidences of wear.

The street department of Worcester, Mass., is using a 1000-pound Detroit electric wagon that is giving excellent satisfaction.

ELECTRIC VEHICLE PRACTISE.

Typical Chassis Frames, Designed for the Installation of Differing Methods of Power Transmission, and Their Characteristics---The Practical Results of Scientific Engineering, They Are Long Enduring Constructions.

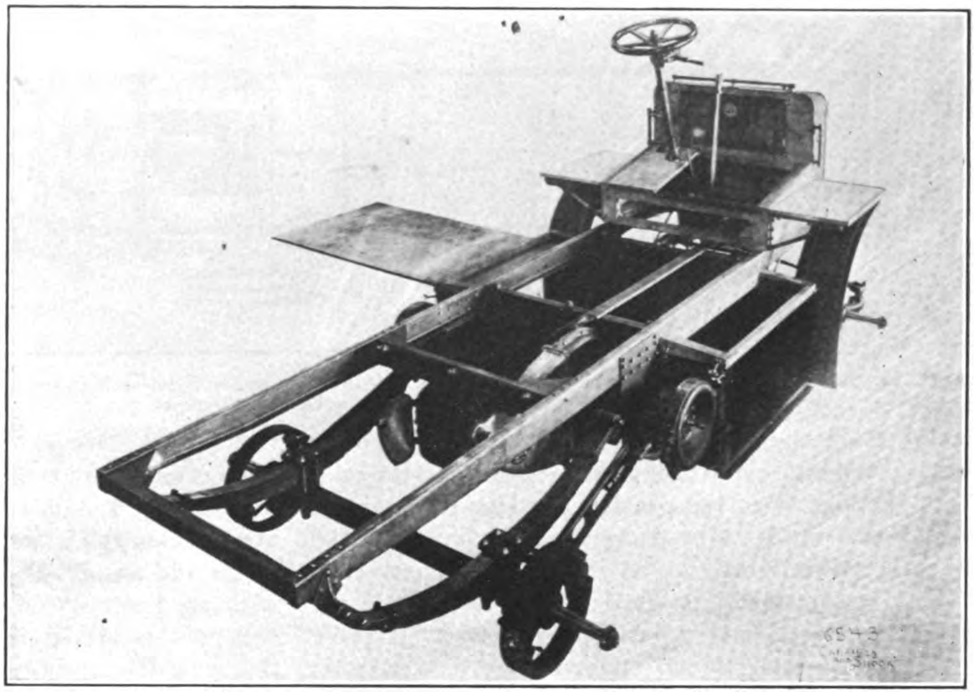
By William W. Scott.

THE electric vehicle represents scientific development and progression in the broadest sense. More than a quarter century has elapsed since the practicality of such conveyances was established and while it is certain enough that many of the characteristics of animal transportations have been retained there is no doubt of the application of well founded engineering knowledge. The original purpose of many who conceived motor vehicles was to adapt a means of propulsion to carriages or wagons, and with rare exceptions there was no disposition to construct what might be better suited to endure the heavy weights and stresses of road conditions. In fact, if the power wagon of today is analyzed one will find that it is surprisingly similar to the animal vehicle. But if comparison be made of the earlier and the present day constructions the application of engineering principles will be evident in every detail.

There is now no absolute standard of electric vehicle design; that is, what is admittedly superior from every viewpoint, and there are numerous means of propulsion that have been well tried and adopted because of the confidence of the builders in them, but there has been no test of these machines under uniform conditions that would establish any one of them as better adapted for given purposes. Throughout the history of the gasoline motor wagon or carriage manufacturers and owners have engaged in varying forms of competitions, racing, endurance contests, fuel consumption trials, hill climbs, braking tests, economy runs and so on, all of which have been conducted with recognized regulations or conditions or to special rules, and under careful observation, for the purpose of determining superiority.

Admittedly a great deal of such data is worthless, because of the difference in capacity of the drivers, the resources of those competing, the character of preparation and the application of technical interpretations of the rules, but these tests have very largely shaped the policies and the endeavors of engineers. The use of power and the attainment of high speed has been a very general result with pleasure cars. With the building of gasoline vehicles for haulage the passenger chassis were often utilized in those first placed in the market, and from these the present types have been developed.

The electric vehicle, especially the service wagon, is an evolution from the pleasure cars, but the development has been along different lines. No tests or trials have ever been conducted in this country, and the machines have been brought to their present day efficiency through observation of actual service under all conditions of use, and the data that have been utilized by the electric wagon designers have been absolutely well established. There is no question that the process is much slower and undoubtedly more costly, for it has been necessary to continue the observations for long periods, but it has the quality of being based on practise and is not founded on the work of specially prepared vehicles handled by experts.



Chassis of Urban Delivery Wagon with Transversely Mounted Motor and Double Chain Reduction, with Battery Box Cover Withdrawn and Motor Case and Dash Compartment Open.

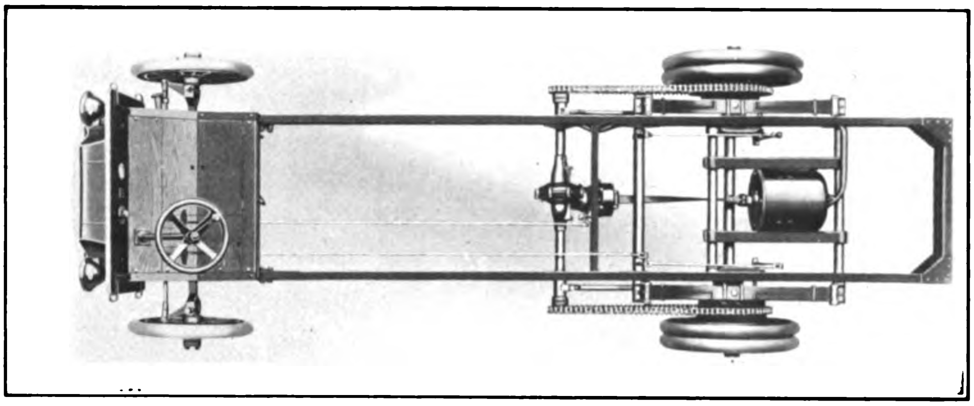
When the statement is made that the electric service wagon is well designed it is not meant that all are equal, but it is intended to emphasize the fact that they are all dependable and reliable. In the first electric pleasure vehicles numerous means of driving were experimented, and some of these were in every way commendable, although given over for what may be

regarded as simpler construction. There are no less than nine different methods of drive employed by designers, whose machines are considered to be standard, but of these but two are used by the majority. This statement is made to emphasize that the means for transmitting power have been seemingly satisfactorily established.

The designer of the electric wagon chassis has not met the same problem the gasoline vehicle engineer has been required to solve. The electrical engineer has seldom undertaken to build a motor. The motors produced by the great electrical manufacturers do not represent the work of the individual. To the contrary they are the productions of splendidly organized engineering staffs, composed of experts of recognized ability, and having unlimited resources and the best of facilities for experimentation, and it is fair to assume that motors designed and built with the latest and most approved tools and shop equipment and by highly skilled labor can be regarded as dependable and reliable. That the engineer has generally used motors so perfected and specialized is an assurance to the public of the quality of the construction, for it is evident enough that until a type is certain to endure and give the rated power it will not be offered in the market.

The motors made by the large manufacturers are sold at much cheaper prices than would be possible were they made in limited numbers, and it is possible with the use of standard productions of this kind to materially reduce the first cost and to minimize the expense for restoration and repair.

The motor vehicle designer does not manufacture batteries. While it is true that one or two firms will build batteries, these are not necessarily a part of the regular equipment, and the products of large concerns that specialize battery making are generally installed. Standard batteries have approximately the same capacity. That is, the same size and type of any given make will yield about the same power, and with conservative rating it is practical to establish a mileage that can be realized with certainty. Batteries have been developed by the manufacturers just as the motors have been perfected, because it has been realized that minimized initial cost, the greatest endurance, increased capacity, and economy of maintenance are material factors in stimulating more increased use, and it might be pointed out that the evolution of both motors and batteries has been accomplished by patient test and observation and not through competition or trial.

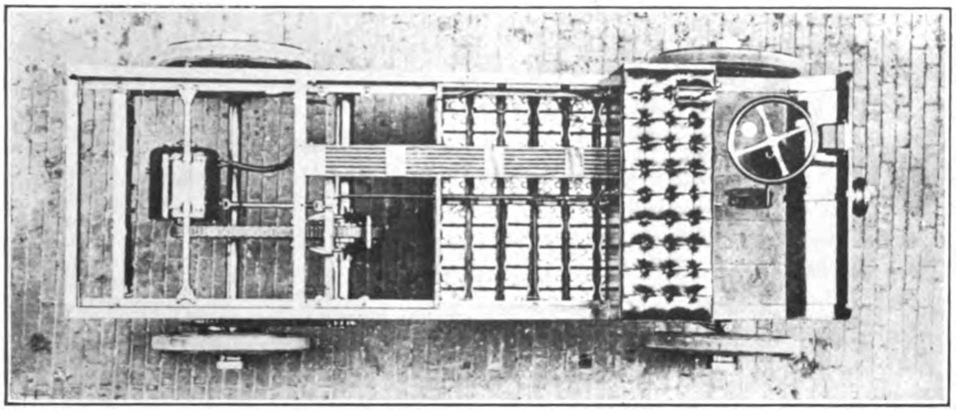


G. M. C. Chassis, Stripped of Battery Box, Showing the Flexible Shaft Drive and the Single Chain Reduction, the Motor Being Supported by a Frame.

The electric vehicle engineer has worked out his problems by a process of elimination. He has realized that he has a definite motor capacity and that a certain energy can be stored in a given type of battery. As the vehicle must carry the battery, and as power must be used to cause propulsion, the purpose has been to minimize the weight of the chassis and body and conserve the energy. In addition the frictional losses have been reduced through the use of roller and ball bearings, by the protection of chains by encasing them, by enclosing and carefully lubricating moving parts, by insuring against excessive wear and providing means of adjustment, and greater utility has been secured by protecting the power wiring, by minimizing current consumption under different conditions of operation, and by safeguarding against accidents resultant from excessive work or from careless or negligent use.

In the conservation of power not a little attention has been directed toward the perfection of spring suspension, for a great deal is dependent upon the manner in which the load is carried. The influence of springs is governed by their form, design, the material of which they are constructed, their elasticity, manner of installation and means for lubrication, and the weight carried. The weight to be supported and its distribution is probably the most important factor, and it is necessary to have springs that are sufficiently elastic to minimize the stresses of road shock and absorb the resistance to tractive effort, and with such strength that they will not have excessive deflection or reflexion. It is well known that a vehicle that has slow spring action is much easier riding and much more economical of tires than one with quick movement, and to obtain springs having this quality much careful experimentation is often necessary.

The majority of designers have located the battery cradle under the chassis and between the wheels for several reasons. First of all this location affords a low vehicle centre of gravity, and while electric wagons are not generally driven fast this quality decidedly lessens the strains upon the chassis when loaded and when making turns. Not only this, but it insures a much easier riding machine and better protects the loads. In some instances the batteries are carried on the chassis frame and very largely upon the forward springs, it being maintained that this construction will afford a well equalized distribution of the weight and not bring an excess load upon the rear construction. The underslung battery gives the full length of the



Columbia Chassis, 2500 Pounds Capacity, with Double Chain Reduction, the Silent Chain Not Enclosed and the Cover of the Battery Box Drawn to Expose the Trays of Cells.

chassis for the body, and with the battery above the chassis frame there is some reduction in the space that is available.

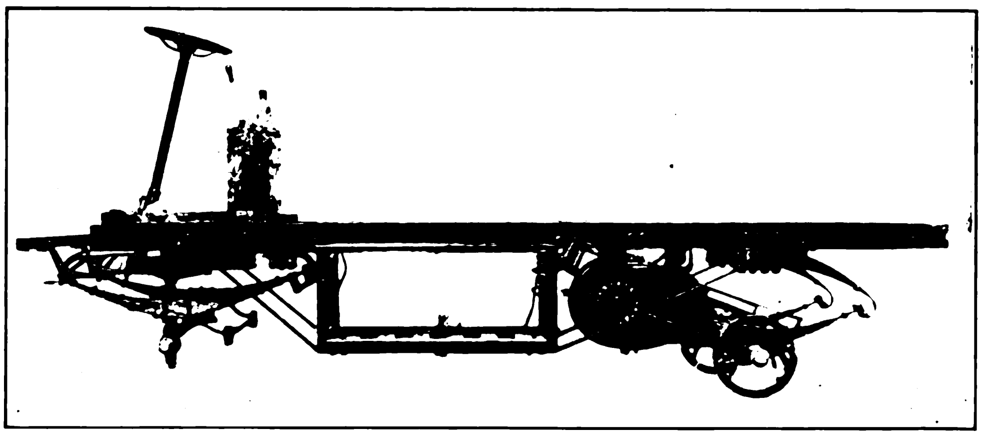
The underslung battery cradle is usually constructed of steel angles for a frame with the box itself of wood or a composition, but wood is the standard material. In some instances the wood is chemically treated to resist the action of the electrolyte that may be drained from a leaky jar or slopped from a cell, and generally there is a series of cleats on the bottom on which the trays of cells rest. With some boxes the bottom is removable, being retained by latches that clamp it firmly, so that when the latches are released the bottom and the trays may be lowered or dropped out of the cradle. Such construction requires a pit with an elevator or jack over which the machine can be driven, the battery lowered, the vehicle pushed away, the battery raised and placed on a truck on which it may be taken to any portion of the garage. This process is reversed for the restoration of the battery or the substitution of another.

With the other type of battery cradle the sides are removable, some being retained by wing nuts or latches or other means, and when taken off the battery trays may be drawn out onto trucks and transported wherever desired. In several instances the sides are hinged at the bottom so that they may be lowered to the level of the bottom, and with one construction at least the sides are supported at that level so the trays may be drawn out upon them, this affording a convenient means for examination. The battery boxes are necessarily provided with drainage in the event electrolyte is spilled, and with ventilation to allow the gas to escape, and to minimize the temperature, for batteries will frequently require the cooling influence of a free circulation of air, especially in warm weather.

Battery boxes are ordinarily covered, there being usually several inches clearance between the top and the trays to insure sufficient ventilating, and the cover is often made so tight that it will effectually drain water and prevent dust sifting into the battery box. Dust or any foreign substance that will cause deterioration of the electrolyte and lessen the efficiency of the battery, as well as oil or water, or possible drainage from anything carried in the body, is guarded against by the tight covering of the battery. Under ordinary circumstances the top of a battery box cannot be reached save by removing the body, and this is a work requiring time, even with good facilities.

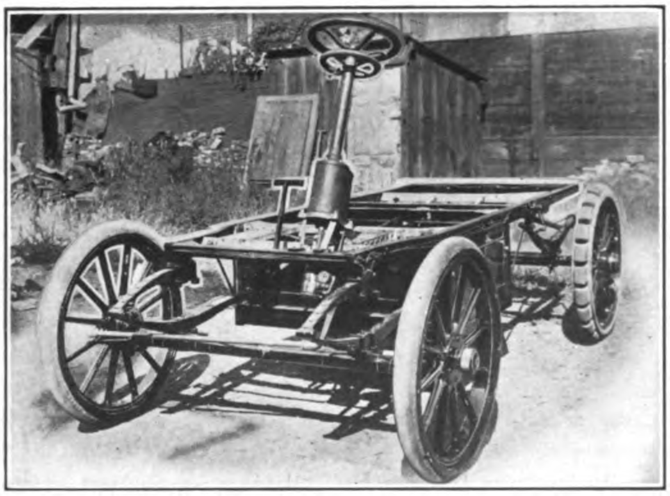
A detail of decided importance is the dimensions of the chassis frame. Because of the desire to minimize weight the material must be high grade and so proportioned as to insure the greatest strength, and it must be reinforced with gussets and cross members. It must resist the weight of the battery suspended from it, but it must sustain the load carried upon it. From one point of view the battery cradle materially stiffens the frame, for the box extends beneath it where there would be a possibility of buckling from the upward thrust when brakes are applied at the rear wheels when moving at a comparatively high speed. Extending from side to side of the frame there is also a resistance against the distortion that would ordinarily be expected with a gasoline vehicle chassis, and with the underslung battery cradle but a small part of the frame is given over to the seat and footboards. The loading space of a given length can usually be afforded on an electric vehicle of comparatively short wheelbase, and the chassis frame is correspondingly shorter. The smaller wheelbase and the comparatively reduced frame do not require as heavy material, and with a high grade steel the weight is minimized.

Spring installations vary somewhat, there being full elliptic springs used on the smallest and lightest



Side View of Waverley Mail Wagon Chassis, Driven by Transversely Mounted Motor and Double Chain Reduction; the Battery Cradle Empty and the Controller Box Exposed—With This Type the Frame Is Trussed.

types of wagons, and while the semi-elliptic type is very generally used, in one or two instances a platform construction has been adopted for the rear. For wagons in excess of 1000 pounds capacity semi-elliptic springs are usually used. The custom where semi-elliptic springs are employed is to secure the forward ends to eyes in the spring horns of the chassis frame and to shackle the rear ends, the drive being through the master leaves of these springs. Practise varies with similar springs for the rear, these sometimes being with the forward ends fixed in spring hangers and the rear ends shackled, or to shackle both ends. In one construction where full elliptic rear springs are used these are mounted so that they have a longitudinal movement in guides at either side of the frame when compressed or released, this eliminating the strain that they would otherwise be subjected to under load when road shock is experienced. With practically all



Chassis of Commercial Worm Driven Light Wagon, Showing the Three-Quarter Elliptic and Platform Spring Suspension, the Steering Gear and the Controller Covered by a Housing on the Base of the Steering Column.

of these the driving thrust is taken by the radius rods that extend from the rear axle to the sides of the chassis frame. Sometimes the forward ends of the radius rods are connected to separate hangers, and generally the connection is made to the hangers that carry the jackshaft when the double chain drive is employed.

The location of the motor in a chassis is extremely important. First of all it is desirable to have the machine so installed that it will be least affected by the road shocks, and it is also necessary to have it well anchored that it may have maximum power productiveness. The double chain reduction, so-called, means a single chain from the motor to the jackshaft sprockets and side chains from the jackshaft to the rear wheels, and with this the motor is installed transversely from a cross member of the frame. With some constructions radius rods extend from the motor case to the rear end of the frame or to a cross member. With others the relation of the motor and the jackshaft is preserved by the heavy chain case that houses the first reduction chain and the sprockets. Generally this is a silent chain and it is operated in an oil bath.

With this construction the motor is located above the rear axle, where it is protected against excessive chassis distortion and the fullest action of the springs minimizes jars and jolts. The movement of the entire assembly is without stresses, and the driving thrust is taken by the housing of the jackshaft from the radius rods.

When the drive is by shaft direct from the motor to the jackshaft the motor may be either in front or in back of the jackshaft, but as a rule the machine is carried in a cradle over or in back of the rear axle and the shaft extends with one universal joint to the motor. The effect of this suspension is practically the same as the other, but the motor is anchored in the cradle or frame and motor radius rods are unnecessary. In one light wagon the motor is mounted forward under the driver's seat and the long shaft extends back to the jackshaft, the battery cradle being divided so as to allow space for the shaft.

In two types of light wagon the worm drive is used, and with the one the motor is mounted on a cradle, formed of the radius rods, that is shackled to a cross frame member so the vertical movement of the axle is not restricted. The drive is direct from the worm shaft coupled to the motor armature shaft to the worm wheel, in which is incorporated the differential. With the other type the worm shaft is carried in a housing incorporated with the rear axle shell, and the shaft extends forward to the motor that is assembled with the axle housing and which is suspended in the chassis frame. Still another construction has the motor mounted on a cross member and the pinion on an extension of the armature shaft drives the bevel gear of the jackshaft.

With all of these the motor is installed under the body and with the one exception of the worm drive first referred to the machine is carried by the frame. There is one other in which the motor is similarly carried transversely under the body of a light wagon, and the drive is from this by a silent chain to a countershaft that has two universal joints, that parallels the motor armature shaft. The other end of the shaft drives a herringbone gear that meshes with a similar gear on a full floating rear axle. The two universal joints in the countershaft permit the movement of the body.

Turning to other motor installations, there is one in which the machine is contained in a hollow shell that constitutes a rear axle of the full floating type. The armature shaft is hollow and at one end of this shaft is a differential gear. The driving shafts are of two lengths, one of them extending through the hollow armature shaft, and both are secured to the differential. Pinions on the ends of the driving shafts drive two large idler gears that in turn mesh with racks in the inner peripheries of the disc or flange rear wheels, and there is a double reduction by this gearing, the idler wheels being carried by fittings on the ends of the axle housing.

In another construction two motors are used, each of which is fixed in a frame rear axle. Between the

motor and the wheel is fixed a gearcase. The end of the armature shaft carries a pinion that engages with the largest diameters of three gears mounted on studs carried on an extension of the motor case that serves as an axle, and the smaller diameter gears engage with an internal gear in the case. The movement of the motor armature shaft gives the three gears a planetary motion within the fixed internal gear and turns the shaft on which the three gears are mounted, which is secured to the wheel hub cap. This same concern builds a truck driven by all four wheels. The motors are fixed in the rear axle and pivoted in the front axle, and connected so that the machine is steered in the usual manner through the front wheels. The outer end of the motor case is a heavy plate that carries an axle spindle on which the wheel is mounted. Between the motor case and the plate is a large gear carried on a heavy stud. The armature shaft pinion engages with this gear. The hub of the gear is formed as a pinion that projects through the cover plate and engages with the internal gear of a drum bolted to the wheel. The wheel is mounted on taper roller bearings and its relation with reference to the gear is perfectly maintained.

Another form of wheel drive is by motors mounted horizontally on the ends of axle stubs that are fitted with disc wheels. The inner disc has a large bearing on the axle stub. The motor armature shaft is in length the diameter of the wheel and carries at either end a pinion. In the outer circumference of the discs are racks and the pinion at one end of the shaft engages with one rack and the other pinion meshes with the other. As the armature shaft is turned the driving effort is transmitted to the racks. These axle stubs are pivoted in knuckles and the machine may be steered by the forward wheels only when driven by these wheels alone, or by all four wheels when four motors are used.

It will be noted with the motor in the rear axle, or with motors assembled with the axles or in the wheels, that they are not protected from the road shocks by springs, but these are surprisingly enduring and long periods of service do not develop abnormal wear.

The power wiring, from the battery to the motor and controller, is well protected, sometimes by metal or fibre ducts, sometimes by wood channels, to insure against wear of the insulation or breakage. The controllers are usually of the continuous torque type and are designed to give four or five speeds forward and two in reverse. Locations differ, some being under the seat, some under the floorboards, some assembled with the steering column, and the control may be by hand lever on the driver's seat, on the floorboards and resembling the conventional brake lever, or on the steering post.

Steering is by the conventional hand wheel and varying forms of gearing and linkage, and one or two brakes may be used. If one only, this is generally on the rear wheels and may be either the internal expanding or the external contracting type, but if two, if both are not on the rear wheels, the second may be on the jackshaft, transmission or driving shaft.

The designers have very generally planned the chassis so that every component that may require attention is accessible. Release of cover clamps gives access to the commutators and brushes of the motors, and comparatively little care is required aside from lubricating the bearings and adjusting the brushes. The battery boxes may be opened quickly, the controllers can be reached in a few seconds, the silent chain cases have ample handholes through which adjustment may be made when needed, and in going over the chassis the extreme simplification is a reason for surprise. There are no reciprocating parts, the means for lubrication are ample, the wearing surfaces are large and there are abundant factors of safety.

The outline given of chassis has been with a view of showing the different constructions and power applications, and to emphasize that while designers have very generally differed as to detail there are certain factors on which they are quite agreed. There is no doubt that the use of high class material, making possible extreme strength and lightness, the scientific assembling of the chassis and its components, the perfected motor, the highly efficient battery, and the careful attention to conservation of current, all the developments from service and long continued practise, have resulted in highly perfected vehicles. It is not meant that the limitations of progression have been reached, for this is far from being the case, but it is absolutely certain that electric wagons as now offered to the people can be relied upon for much more than is claimed for them.

(To Be Continued.)

The Spencer Wire Company, Worcester, Mass., has in service a 3000-pound Detroit electric delivery wagon, which is used for city and suburban haulage of all kinds. The company produces bookbinders' wire and much of this is shipped, requiring frequent trips between the factory and the shipping terminals.

The American Express Company has in its service at Los Angeles, Cal., two Baker two-ton wagons that are fitted with the standard body equipment adopted by that concern. These have been in use since about the middle of October and on routes too long to be covered with even two horse wagons, for the average mileage is from 35 to 40 daily. The machines are kept at the stable of the company, where a charging panel has been installed, and the attention necessary is given by the employees.

The Empire Electric Vehicle Company has been formed at Owego, N. Y., which is to manufacture electric service wagons and, probably, pleasure carriages. One of the promoters of the enterprise is Theodore D. Gere, who was for more than a year one of the receivers of the Champion Wagon Company of Owego, who has been convinced of the possibilities of the electric vehicle and has interested several others who have joined with him in the formation of the company.

ANNUAL "EXIDE" DINNER.

Vehicle Manufacturers, Dealers and Agents Guests of Electric Storage Battery Company.

A company of 220 assembled at the Mid Day Club, Chicago, Ill., the evening of Feb. 5, the occasion being the annual dinner tendered by the Electric Storage Battery Company of Philadelphia, Penn., to electric vehicle manufacturers, electric vehicle dealers and Exide battery distributors, practically all of the leading concerns of the industry being represented. The invitations had been very generally distributed and this brought together men from nearly every state and principal city in the nation.

The sales managers and department heads from the different offices of the company constituted a reception committee that received the guests, and after a period of fraternizing a dinner was partaken of. The menu was tempting and to it the company did full justice. In the unavoidable absence of Herbert Lloyd, president of the Electric Storage Battery Company, Charles Blizard, third vice president, presided. At the conclusion of the dinner a programme of vaudeville entertained the guests.

The Annual Dinner Given at the Mid Day Club, Chicago, Ill., to Electric Vehicle Manufacturers, Dealers and Exide Battery Distributors, by the Electric Storage Battery Co.

The Electric Storage Battery Company is known as the oldest concern in America making storage batteries, and its products are generally used by a very large percentage of electric vehicle manufacturers. The annual "Exide" dinner is regarded as being one of the enjoyable features of the automobile show week at Chicago.

At the service wagon division of the Boston automobile show eight different makes of electric vehicle will be exhibited, and one of these, the Edison, for the first time.

SHIFTS CARS WITH TRACTOR.

Pennsylvania Railroad Replaces Horses with Big Electric Machine at Jersey City.

An electric tractor of very large capacity, built at the shops of the company at Altoona, Penn., from designs by P. A. Buckwalter, chief electrical engineer of the company, has been placed in service at Jersey City, N. J., where it is used to haul cars through some of the streets. Several large concerns receive frequent consignments of freight in carloads, and it has been the custom for years to deliver these cars by hauling them on tracks laid in the streets. Because of the conditions locomotives could not be used and horses were not satisfactory in hot or bad weather, and occasionally tackle was used to perform the work. Several short curves limit the speed of the cars. Heavy trucks were tried in the place of horses, but none was of sufficient weight. The railroad company then undertook to build a tractor, and the result is the Buckwalter machine, which has proven very satisfactory.

The tractor is 22 feet length and the tread is 72 inches, so that with the 10-inch tires the extreme width is approximately 92 inches, the machine being designed to be driven with the wheels outside of the rails. The wheelbase is 144 inches and the wheels are 60 inches diameter. The weight is 28,850 pounds. The tractor is driven in either direction without turning and it is steered and driven by all four wheels. The big steel wheels are mounted on steering knuckles and on each wheel is fixed a large external spur gear. Two electric motors, having nominal ratings of 10 horsepower, but with an overload capacity of 250 per cent., drive through spur gearing giving a double reduction to the two jackshafts. These jackshafts are carried in heavy bearings and have the usual differentials, with universal joints at the outboard ends, so that the spur pinions mesh with the external gears on the wheels. The pinions just clear the wheel rims, there being a large reduction by the driving gearing, and the relation between the axles and the jackshafts is such that a line through the centre of a steering pivot will also pass through the centre of a pinion, insuring positive driving effort.

The chassis frame is suspended on semi-elliptic springs and under the frame is carried the Edison 80-cell battery. This has a capacity of 450 ampere-hours and the tractor has a mileage under normal conditions of about 40 miles, with a maximum of eight miles an

hour. The chassis carries a large cab body with side and end windows, and in this is a steering wheel, which is mounted as is that of a vessel, and is operated by the spoke ends. This affords more certain control than the usual type of steering wheel used for automobiles. The hand levers are located at either side, one full set at the right of the driver, no matter what the direction of movement of the machine. The speed lever swings in the slots of a quadrant that are divided by a bridge, there being three speeds forward and three in reverse. Going in one direction, to illustrate, the forward movements of the lever give the different speeds, and when the lever is brought against the bridge it is in a neutral position. To reverse the lever handle must be changed to the socket on the other side of the bridge and the backward movements give the different ratios. It is impossible to reverse the tractor without this change of the lever and unintentional or accidental reversing is insured against. The tractor is fitted with an air brake and the usual couplings, and the pressure is supplied by a motor driven pump. When the air brake is used the control lever is thrown into neutral position. There is a hand brake that is operated by a wheel located in the cab. The tractor is fitted with standard automatic drawheads that may be uncoupled by outside levers, and these are cushioned by pneumatic cylinders that will sustain 10,000 pounds pressure before the pistons will be forced to the bottoms. The tractor wheels are fitted with steel rims on which are installed the rubber block tires, there being sets of three blocks on steel bases arranged in two rows. The tractor is practically noiseless and is so well suspended that it rides very easily, even over the tracks and the paving.

WESTINGHOUSE CHARGING PANEL.

Sectional Equipment That May Be Increased to Meet the Demands of Garage Business.

The Westinghouse Electric & Manufacturing Company, East Pittsburg, Penn., has produced a charging panel now ready for marketing that is designed to meet the demands of those who have comparatively small space and yet desire to increase facilities whenever this may be desirable. The ordinary charging panel consists of a slate tablet on which are installed the switches, the ammeter and voltmeter, and the fuses, and which is connected with a rheostat located conveniently, either on a shelf or gallery or possibly on the floor. Very general construction is to place the rheostats side by side on a shelf and to have the panels, often designed for from four to six batteries, erected side by side, forming a continuous board of considerable length.

The Westinghouse equipment differs from this in that the panel frame carries two boards, both small, the one at the top carrying the meters and the lamps, switches and connections, and the lower the fuses. With the two sections two batteries may be charged simultaneously, but it is possible to place between these two as many additional sections as may be desirable, the only limit to height being the space and the convenience in reading the meters, making the connections, etc. Back of the panel is a frame designed to carry two rheostats for each section, and as the panel is increased in size rheostats are also added. This construction makes it possible to install a charging equipment that will be sufficient for from 12 to 16 batteries in practically the same room that would be necessary for from four to six, and at the same time to economize the initial cost, as the panel may be increased at comparatively small expense.

The panel may be used by connection with the main line if the current is direct, but if it is alternating then a motor generator set is necessary. Or it is possible to generate current with a generator driven by a steam or gasoline engine.

EXCLUSIVE ELECTRIC GARAGE.

Second Public Station, with Capacity of 30 Machines Opened at Hartford, Conn.

The second exclusive electric garage has been opened at Hartford, Conn., by the Sigourney Electric Garage Company, at 117 Sigourney street, in a building especially built for the purpose, which has a capacity of 30 vehicles. The Hartford Electric Light Company for a number of years maintained its own garage and incidentally gave service to a number of owners of electric vehicles, but when the company became agent for service wagons and began to promote the sale and use of such machines it afforded to its customers so far as possible garage attention.

The Sigourney Electric Garage Company will afford service to both pleasure and service wagons and is located in what may be regarded as a residential section. The building is 100 feet length and 35 feet width and admirably lighted, with entrance at either end. The floor is cement and is so built that it may be frequently flushed. The charging equipment will give simultaneous service to 16 vehicles, and up to a 56-cell battery. The current is supplied by the regular commercial mains and as it is alternating it is rectified, the rectifier being installed on the roof girders to economize the floor space. Later on it is proposed to install a motor generator set, which will be more economical than the present equipment, and will better serve the requirements of the management.

The garage is well equipped throughout, being heated by hot water, and an air compressor affords a vacuum cleaning service that is especially effective in cleaning cloth upholstered vehicles, to say nothing of the other uses that may be made of it. The president of the company is C. H. Brooks, who was formerly with the Westinghouse Electric & Manufacturing Company at Pittsburg, Penn., and W. J. Gengras is treasurer and secretary. The garage has been well patronized and the prospect for the future is excellent.

TIRE ECONOMY AND TIRE NEGLECT.

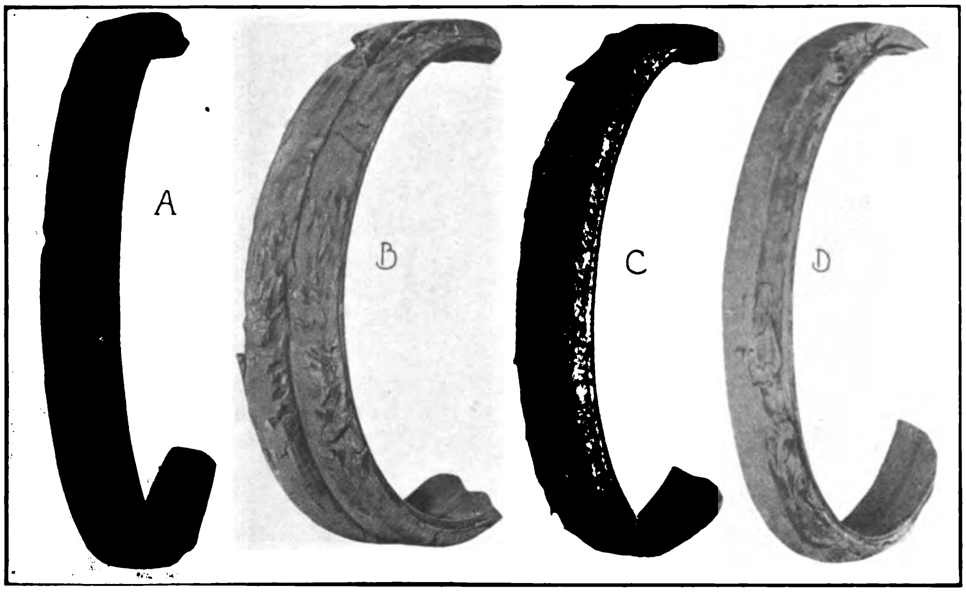
Wheel Shoes Designed by Maker and Engineer for a Stated Work and Mileage, and Are Usually Adequate---Consequences of Overloading, Careless Driving, and Innumerable Other Conditions Within the Owner's Control.

THE endurance and service of tires is given a very large degree of attention by the owner of a motor wagon or truck, so far as the expense for renewing equipment is concerned, and it may be said that, with the usual form of guarantee by the tire manufacturer, this is represented by mileage, but it is seldom that the men who are so solicitous as to the cost a mile will insure themselves the maximum of results. This is not through ignorance of causes for abnormal wear and deterioration, but generally because of neglect. There may be exceptions to this, but such are comparatively few.

Tire equipment is ordinarily determined by the manufacturer of tires, and it can be said that the custom is for the designer of a motor vehicle to estimate the weight of his machines and to determine the size of the wheels that shall be used. It may be that the advice of the tire expert is sought and the wheel builder consulted, but generally the vehicle engineer decides the sizes of the wheels on the basis of what is regarded as standards. To illustrate: Many of the makers of tires have in tabulated form the maximum weights that should be carried by wheels and shoes of differing circumferential and cross section diameters. These are prepared from estimate and experience and are considered to be desirable.

The designer of a vehicle will estimate the weights and with such a tabulation determine the size of the tires to be used. To carry such a tire a wheel has been estimated. It is known that from 60 to 95 per cent. of the load may be borne by the rear axle, and in addition to the weight of the chassis and the load there is to be provision made for the tractive effort. The stresses are proportionate to the weight supported by the tires, but while the front tires must endure the road shocks the rear shoes must be sufficient to resist the traction and braking strains.

It is general practise to have truck rear tires of a dual type with from 50 to 100 per cent. greater width than the front shoes, and with light service wagons the equipment may be of the same sectional area, though frequently the rear tires may be somewhat larger than the front. Assuming that the wheels have been designed and the shoes determined by the engineer creating the machine, it is reasonable to believe that the normal sizes have been provided because expense is to be considered. There are instances where what may be believed to be extreme sizes have been specified, but these are not frequent.



Causes of Tire Destruction and the Results: A, Use of Non-Slipping Anti-Skid Chains; B, Torn by Skidding or Locking of the Brakes; C, Worn by Driving at Excessive Speed; D, a Consequence of Overloading.

The selection of tires may be regarded from two aspects. The one is to choose a normal dimension from the front and the rear wheels, basing expectation of a stated service on the price paid, or to specify larger sizes and expect correspondingly greater mileage. Measuring the use by the cost it may be held that there will be the same ratio of expense a mile, the larger wearing longer, but giving no greater mileage than would be expected from the difference in cost. In other words, if a certain service could be realized from one size of tires, it would be logical to have additional mileage proportionate to the expense of larger shoes. If the larger shoes showed a smaller cost a mile then they would be regarded as the better equipment.

Experience with pneumatic tires may be paralleled with solid shoes. One of the best known of American pleasure cars has always been equipped with large tires, and two of the strongest claims made for this machine have been easy riding qualities and minimum tire expense. These claims have been based on practical knowledge and actual results. The mileage cost has been surprisingly low when contrasted with other makes of cars, although the initial expenditure was relatively more. The same result has been found with solid tires, and the larger the shoes the better the en-

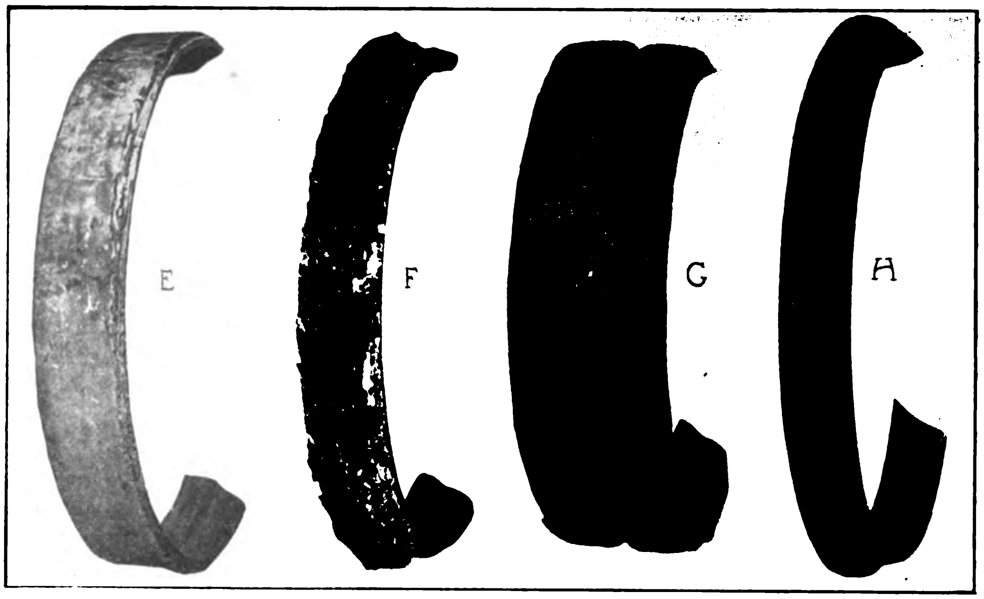
durance. The reason is only what could be expected, for the increased size of the wheel means greater wearing area a revolution, there is lessened influence of road surface inequalities and obstructions, there is a longer lever arm and consequently more effective tractive effort and lesser traction strains, greater efficiency in braking, and, quite as much as any other factor, decreased effect of use upon the mechanism.

It is customary for tire manufacturers to guarantee service in mileage, and while this is a measure that may be reasonably accurate and satisfactory it is certain enough that condition of road surfaces is a very potent factor that cannot be considered as average. By this is meant that a tire will wear much faster on a rough highway than on a smooth, and to insure equal mileage of tires used on either class is not practical, although it is usually done. Besides this there are numerous other influences that are unequal, the power of the vehicle, the weight carried a square inch of tire surface in contact with the road, the action of the clutch, the action of the brakes, the judgment of the driver, the percentage of grade, both ascending and descending, to level, the speed at which the vehicle is driven loaded and unloaded, whether or not the wheel spindles are true, and the attention the shoes receive in the garage and on the road.

One of the most general causes for excessive tire wear is overloading. To understand this an instance may be assumed, that of a three-ton truck. The tires are provided by the manufacturer and the wheels equipped after the designer or engineer has determined the weight of the chassis, and reasonable allowance has been made for a body. If the tires are what may be regarded as standard for vehicles of that capacity they are built to endure such loads as the truck is built to carry normally. If the owner of the truck wants to "make money" he increases the load from 1000 to 2000 pounds. This means the tires will carry from 16.66 to 33.33 per cent. more than they were intended by the designer or the manufacturer, and it is obvious that there will not only be wear proportionate to the overload, but it is estimated that it will be increased with the square of the extra weight, so that instead of increasing his earnings in ratio to the freight the tire expense will be quadrupled beyond the normal load. That is to say, that it will cost more to carry that fourth ton than it did the three tons, to say nothing of the extreme wear upon the vehicle from every point of view.

While it is difficult to estimate the wear that is caused by overloading it is not unreasonable to realize the fact that a tire made to endure a stated load will have a certain life. As this life is shortened by overloading, because of the stresses beyond what the tire is built to endure, the mileage must necessarily be decreased and the cost a mile increased. The overloading may not be constant, but the tire is weakened by the abnormal strains and it will deteriorate very much more rapidly than were it used within its limitations.

In tire manufacture no provision is made for variance in speed. The wagon and truck tires produced are built with reference to service, or a certain mileage under a specified load. Now it is evident that the wear is much less with a vehicle moving at six miles an hour than at 10 miles, and that slow acceleration is least destructive. Traction is obtained by weight in track vehicles, unless in the event of a railroad where it is necessary to have other means of counteracting the influence of gravity, but with motor road conveyances it is secured through the high coefficient of friction of rubber or rubber compound and the surface of



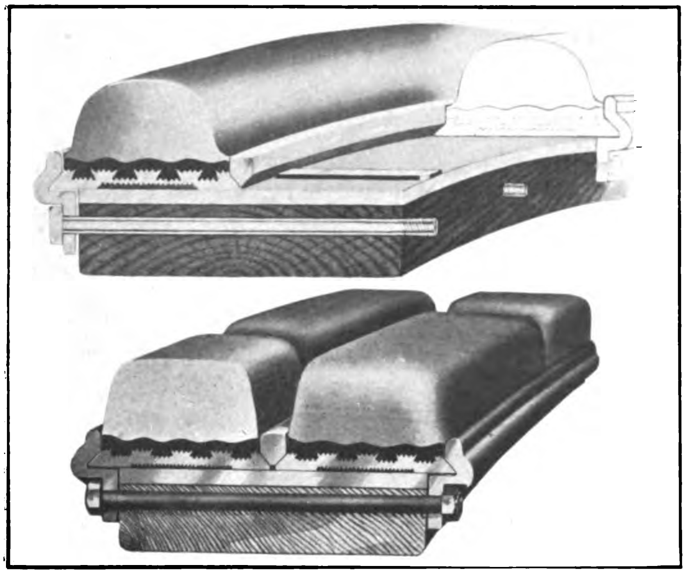
Effects of Neglect and Careless Use: E, Worn by Wheels Not in Alignment; F, Driven with Heavy Loads Over Bad Roads; G, the Results from Neglecting Cuts and Surface Damage; H, Cut to Fragments by Driving in Car Tracks.

the ground. The effect of tractive effort cannot be noted so far as the highway surfaces are concerned, but the condition of the tires may be constantly noted. This may be doubted by some. But it may be easily demonstrated.

In the event of a wheel being out of true, from a sprung spindle or other cause, and the wheel revolves irregularly, the surface of the tire will have a wavering movement on the road. While the wear resultant from a regular revolution would not be apparent the sidewise motion will be extremely destructive. There will be no greater weight carried but in a comparatively few miles the shoe will be greatly damaged. The front wheels carry the load and are pushed along. The tires of these wheels endure generally longer than the larger shoes of the rear wheels, and this from the fact that they are not required to endure the additional strain caused by traction.

Where brakes are not well adjusted and do not

hold equally it is evident that there is abnormal strain borne by one and that which is most firmly clamped will have to do a much higher work than its mate, and



The Goodrich Quick Detachable Dual Truck Tires: The Upper, the Solid Bands on Hard Rubber Bases, Vulcanized to Steel Bands, and Retained by Side and Centre Flanges; the Lower, the Rubber Blocks, on Rubber and Steel Bases, Used with the Same Rims.

the tires will be worn proportionately. If the machine skids there is a result very like that when a wheel spindle is sprung, although for a brief duration, but the wear cannot be avoided. Skidding is caused by unequal traction and when a vehicle skids it is stopped with extreme strain upon one, and never two, of the shoes.

With these influences which it may be claimed cannot always be avoided, there is the factor of a load unequally distributed, which necessitates the traction wheels generally to endure strains which are as destructive as poorly adjusted brakes or skidding. One wheel must necessarily carry more weight, and sometimes much more than another, and the tire so overloaded must be worn in the proportion that it is overworked. If the brakes are well adjusted and are applied so that they grip quickly and the wheels are "locked," the tires must slide along until weight overcomes momentum, and the consequence is the extreme wear of the area in contact with the ground. The most efficient braking from the viewpoint of the engineer is to so retard the action of the wheels that the machine is brought to a standstill without skidding, and yet the slightest additional pressure on the brake would cause skidding. The most effective braking effort is made when a brake shoe is so adjusted that it will clamp the drum and retard the wheel without jar or jolt, and to do this there must be clearance sufficient for the drum to revolve freely, yet the movement of the pedal or lever should be so slight that contact is made practically the moment that pressure is applied by foot or hand. One of the greatest causes of tire wear is the poor adjustment of brakes, and this is a condition that must be known at all times when the machine is in service.

Much the same result so far as tires are concerned follows the use of a clutch that does not engage easily, or is not properly used. As a matter of fact this condition is inexcusable, for the driver must of necessity be aware of it, and besides the matter of tires there are the undue stresses to which the entire vehicle is subjected. Theoretically and practically the clutch should be so used that the machine will be started without a jar or jolt, and this use is expected by all designers and engineers. The clutch may develop a defect, but there are remedies that may be applied according to the type of device in the machine.

The maximum or normal load limit for tires has been established by some manufacturers, and these figures will serve to indicate the sizes on which guarantees have been established by two of the largest concerns in America. The accompanying sketches will illustrate the points at which measurements are applied.

Considering single and dual tires, it will be noted that the letters A, B, C, D, E and F are used with either, but the figure 2 is used with these designations with the dual type. The tabulations are those of the United States Tire Company, and it may be stated that the carrying capacity of these, from three to seven-inch sizes, is the same as the capacities of the B. F. Goodrich Company. The limitations are self-explanatory, and the drawings are given with a view of showing the manner of determining dimensions.

There are practically two forms of truck tires, the band and the block types, and the band is the older and the more generally used. Bands as originally constructed were with bases of fabric and were vulcanized to the channels, and clincher or straight flanges prevented the bands being "shed" should they become

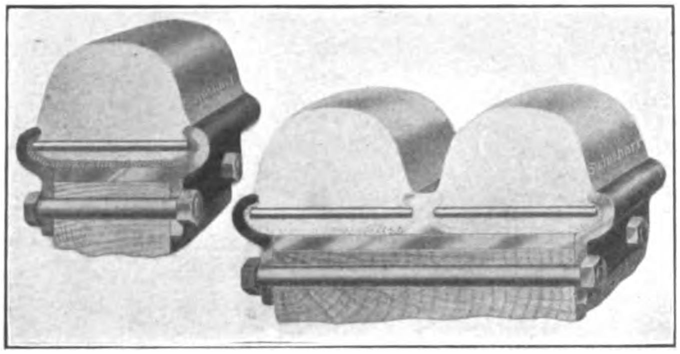
Section of Republic Double and Single Solid Band Truck Tires on Metal Base, Drive Fitted to Rim and Retained by Staples.

loosened. Next came the shoes with fabric base that were retained on the wheel rim by a removable flange and bolts. Tires of this type were reinforced with



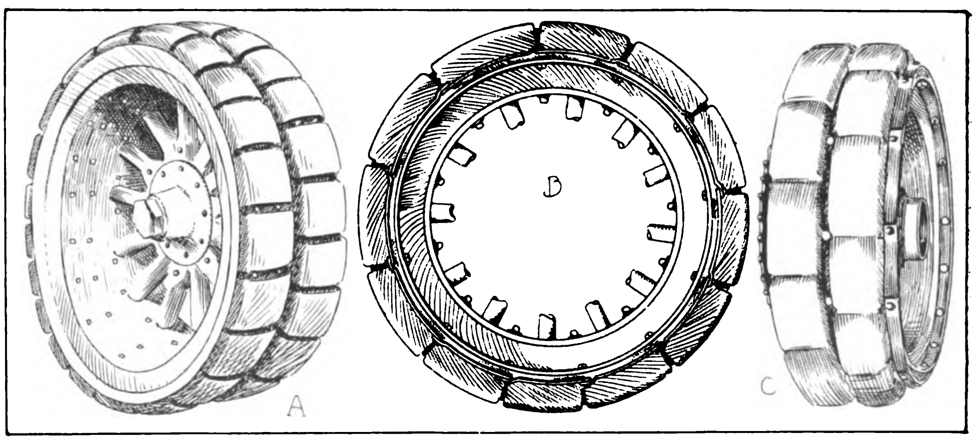
Single and Double Swinehart Motor Truck Tires on Quick Detachable Rims, the Cross Wires Engaging with the Flanges and Retaining the Shoes.

longitudinal and cross wires, with varying structural design, and with the realization that a quick detachable or demountable tire is more important with a service wagon than with a pleasure vehicle attention was directed toward development of these shoes. To-day the majority of heavy tires are demountable, but some of the equipment for light vehicles is made in much the same manner as the carriage tires, a solid rubber band being mounted in a channel with flanges that prevent stresses throwing the band from the rim.

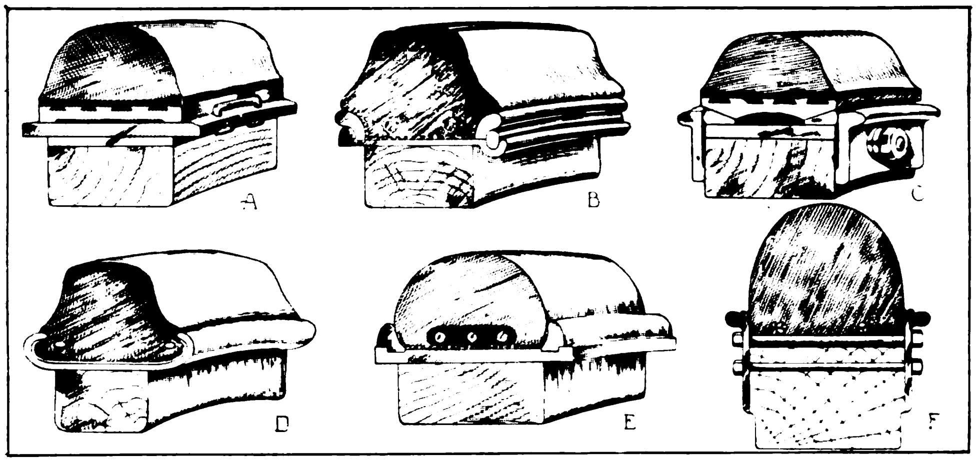
The demountable tires necessarily have a rim or channel of sufficient strength to endure under the weight supported against all road shocks, and these rims are of sizes to fit wheels of standard dimensions. In this respect the standardization of wheel rims by the Society of Automobile Engineers has been extremely beneficial for tire manufacturers, wheel manufacturers, and to those who own and operate all forms of automobile vehicles. The rims are usually a good quality of steel and while the inner circumference is generally smooth, the outer circumference is machined or formed so as to resist the stresses upon the tires. On the outer circumference and filling the channels or grooves a layer of vulcanite or hard rubber composition is vulcanized. To this the tire itself is similarly attached, the entire structure being built by the tire manufacturer and cured to the formula or by the processes which each has determined is the best. There are other methods of making service vehicle tires, some makers still producing them with the fabric and reinforced base. These, however, are not what is known as demountable, although they may be quickly removed. The one fault that must be contended in removal is the rusting of the rim, unless special provision is made to prevent rust, and then its consequent destructive influence on the tire base is a factor of large importance.

The block form of tire is with a number of blocks or cakes of rubber, vulcanized to bases of differing material, which are inserted into the specially designed rims and retained by bolts or rods, or they are retained to the rim by a collar that is bolted to it. One form of block is made with a flange about it, and between each block, transversely of the rim, is a plate bolted at either end. By the removal of a single plate it is possible to renew a block whenever necessary. While single row block tires are used, the type generally in service consists of two rows, these being designed for rear wheels, and serving the same purpose as any dual tire. When arranged the blocks lap; that is, the spaces between the block of one row are about the centres of the blocks of the other row. This arrangement provides for a cushion of rubber beneath the wheel at all times, and lessens the strain that would certainly result were the spaces in the same relation in either row. There are several forms of truck block tires where the blocks are shaped to be inserted in the rim with a diagonal relation to the face of the rim, with the length of the blocks across the wheel. With this form the wear is against the width and not the length of the block, and the space between them is somewhat wider. Such blocks have what is known as a "spiral" effect and it is maintained by the makers that they have special tractive qualities that minimize skidding. They are not made for dual tires, however.

The band tires that succeeded those vulcanized to flanged channels, which were the earliest type, were next made with bases of fabric and vulcanite or hard composition, and it was necessary that these be a very close fit to withstand the strain and to insure against creeping on the rims. This form is still used to some extent and, as may be assumed, they can only be installed on the rims by the use of special equipment, this being in one sense a press. With tires of this type there are generally several transverse channels in the rim into which ribs or beads on the base fit. These were succeeded as types by those in which wires were imbedded transversely in the base of the tire which projected beneath the clincher flanges of the rim, one flange being integral with the rim and the other being retained by bolts.



Sectional and Block Tires: A, Victor Sectional Truck Tire; B, Side View of Portage Truck Tire; C, Perspective of Portage Truck Tire.



Goodyear Single Tires: A, Metal Base Truck Tire; B, No-Rim-Cut Solid Tire; C, Demountable Single Tire; D, Goodyear-Motz Truck Tire; E, Hard Rubber Base Tire; F, Solid Endless Tire for Fire Apparatus.

Another form was that in which several stout wires were vulcanized in the base and these were brazed or connected so as to be practically continuous. The purpose of such wires is to strengthen the tire and prevent the base stretching and insure its resisting the strains of traction. Another type has a hard rubber centre or core containing several wires, but at either side is a section of rubber compound that fills the flange,channels of the clincher rim. With the demand for demountable tires the natural development was a form of rim that would retain the tire and be clamped to the wheel rim with flanges or rings, generally secured by bolts. There are tires made which have the channels so tight as to be a drive fit, and these are retained on the wheel rims by staples bent in the edges of the wheel rims, but these are not generally used.

Dual tires are, if of the band type, two shoes retained on the rim by two locking rings or flanges bolted on, with a centre ring that either fits over or under the edges of the rim channels. Generally there are wedging rings that are installed between the wheel rim and the tire channel, and when these have been forced into place by tightening the bolts the tires are held immovable. Tires of this type are held rigidly and yet may be removed readily when the bolts are loosened. It is not possible for a rim of this kind to become "frozen" with rust and it may be taken off and another installed with comparatively little loss of time.

The block tire, it is claimed, has the advantage that should any one of the sections be damaged it can be taken out and another replaced at a comparatively small cost and with but little effort, and that there is seldom the necessity of renewing more than several of the blocks. The blocks, in some makes, are so close together as to form practically a sectional tire, and the manufacturers maintain that in effect they have all the qualities of both the block and the band types that make for satisfactory and efficient service.

The following are the dimensions of leading makes of wagon and truck tires, though it cannot be said that these have been recognized as standards, for each maker has his own sizes and proportions, based on long experience, it is certain enough that these are fairly representative. Some tire manufacturers, moreover, claim that the shape and construction has as much to do with endurance as material and workmanship and methods of curing:

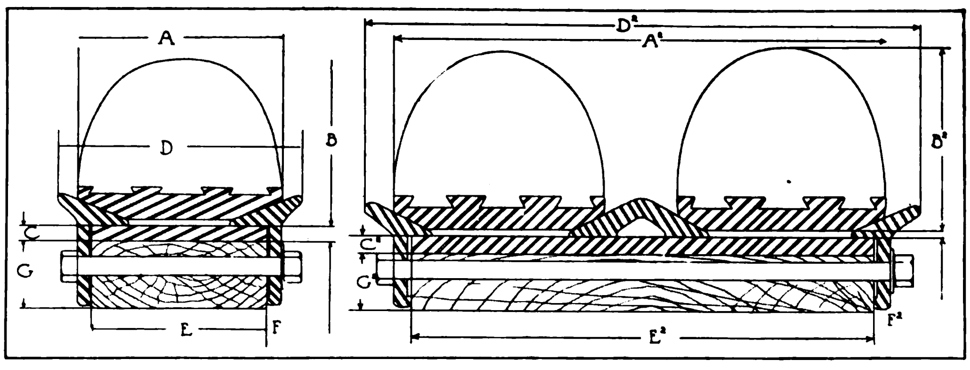
7"	"	6750	7125	7500	7875	8250	8625	10

The same company makes a different tabulation for dual block tires, but the capacities are based on the cross section and the diametrical measurements. It will be noted that the dual is only provided for up to width of eight inches, and that its capacity is rated as slightly less than the band tire. These dimensions are for maximum loads:

Size	M. P. H.	34"	36"	38"	40"	42"
3½"	14	2350	2500	2650	2800	2950
4"	13	3000	3200	3350	3550	3700
5"	12	4250	4500	4750	5000	5250
6"	10	5500	5850	6150	6450	6800
7"	10	6800	7150	7550	7950	8300
8"	9	8050	8500	8950	9400	9850

The only safe and certain means for tire economy is to know the exact weight of the wagon or truck. This can be ascertained by weighing either end singly, a method that is known of every weigher, and with this as a basis learn what the machine can carry up to the maximum allowed by the tire manufacturers for the equipment. Then with a load of the maximum weight the vehicle should be again weighed, which will give the proportions carried by each wheel. The difference between the weights loaded and unloaded will show what each tire is required to carry. If it is found that the weight exceeds the tire capacity it will be the best of judgment to increase the size of the shoes. This will involve the replacing of the wheel rims and the use of larger tires, an expense that may not appear justified, but it is better to make the investment in the rims, which cost but little more and may be used for years, than to believe there can be gain by using small tires.



General Dimensions of United States Standard Motor Truck Tires and Demountable Rims, to Be Used with Tabulations of Tire, Flange, Band and Felloe Sizes.

An instance of this character was brought to the attention of the writer where the owner of a truck endeavored to use eight-inch dual rear tires on a 36-inch wheel. The tires wore rapidly and instead of replacing the wheels a 10-inch rim was installed on each and tires of that width used. This was a decided improvement, but still it was believed it would be economical to increase the rim two inches more in width and use a 12-inch or six-inch dual shoe, and to strengthen the wheel rim by building in an extension to the felloe. The cost has been more than a sufficient equipment would have incurred originally and at best it is a makeshift, but it can be accepted as a fact that when a hard headed business man will twice increase the size of the tires of his truck his only interest is to economize.

MACK BURNING DISTILLATE.

California Concern Utilizing Specially Designed Machine for Handling Its Lumber Business.

One of the largest trucks used in lumber hauling in Los Angeles, Cal., is a five-ton Mack, made by the International Motor Company, New York City, that was recently put in service by the Kerckhoff-Cuzner Lumber Company. The truck was built especially to the order of the company and the length of the bed back of the seat measures 18 feet two inches. Twenty-six foot lumber is carried with ease.

The truck has been equipped with the Barnard carburetor and burns distillate. A novel loading device has been perfected by the company at the lumber yards. When a load is assembled it is hauled by wagons to a specially built crane which, when the load is complete, picks it up and places it on the waiting truck. The latter is idle only an average of five minutes while being loaded, which greatly increases the amount of work possible to complete with it in a day.

BRAKE AND SPRING CONSTRUCTION.

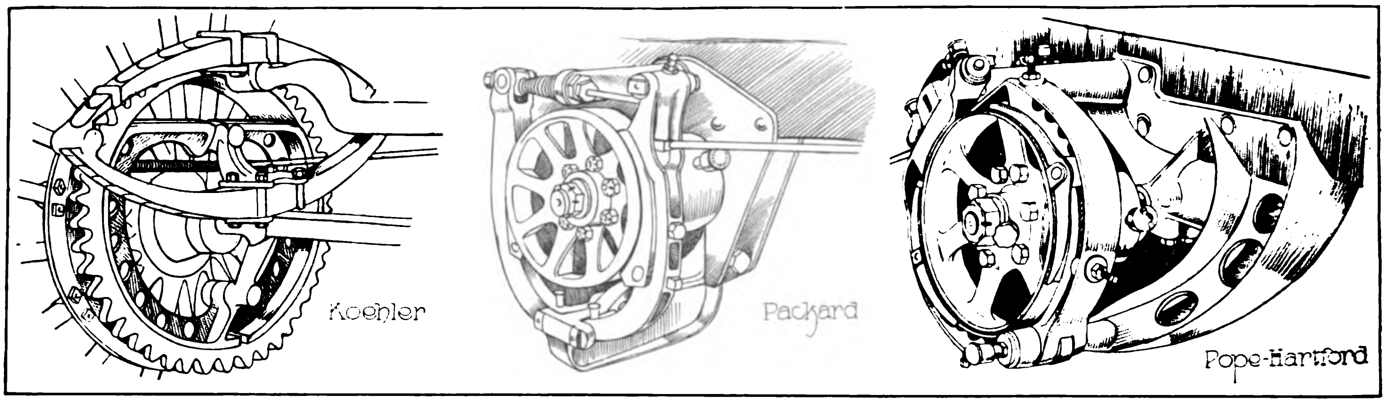
How Designers Have Perfected Control and Improved Suspension to Secure Greater Efficiency and Endurance of the Chassis.

EVEN casual examination of the chassis exhibited at the New York show demonstrated that a great deal of attention had been given by engineers and designers to the improvement of suspension and brakes, and that there is keen realization of the need of perfecting spring action and control. It can be accepted without question that the endurance, maintenance and economy of use of the machines is to a large extent dependent upon the springs and the manner of their utilization, and it is necessary for the protection of the vehicles and the property and lives of others that the control be such that when occasion may require they may be stopped in the shortest time and distance.

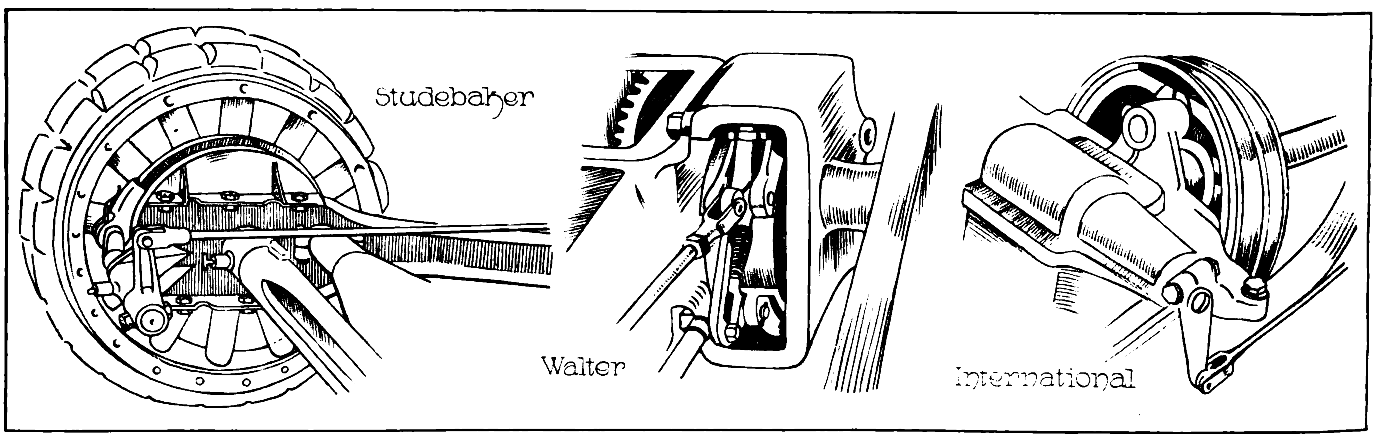
It is apparent that by compounding the brake linkage any pressure of shoes or bands may be obtained, but it is also certain that with the wear of the shoes or bands and the connections of the links a large measure of the efficiency may be lost. To prevent wear from abrasive substances brakes are often enclosed, and then the wear can only be judged from the movement of the levers and the effects when used. If not easy of access they are frequently neglected and efficiency will rapidly decrease. Brake band linings or shoe facings will wear and if this condition is known it may not be changed because of the work entailed. For these reasons the designers have devoted their attention to brakes that will be certain of operation, will be accessible when adjustment is needed, and will wear for a very long period without loss of efficiency.

Perhaps one of the most interesting features is the locomotive type, so-called, of brake developed for the Packard and Pope-Hartford machines, and is fitted to all these wagons of three or more tons capacity. In the Packard trucks the jackshaft hanger has been designed to carry the brake shoe shaft, the hanger being a heavy steel casting that has an extension at the lower part. This extension is supported by webs and it carries the large bolt which secures the shoes and on which they move. The shoes are webbed to secure lightness and strength and they are linked at the top by a rod on which is a spring. The brake rod is connected so that a direct forward pull is given and the shoes are drawn together, clamping a drum or pulley on the end of the jackshaft. This is the service brake and is used constantly. The construction gives a very large area of braking surface and while the metal shoes will wear slowly they can be adjusted quickly and can be renewed at slight expense when no longer serviceable.

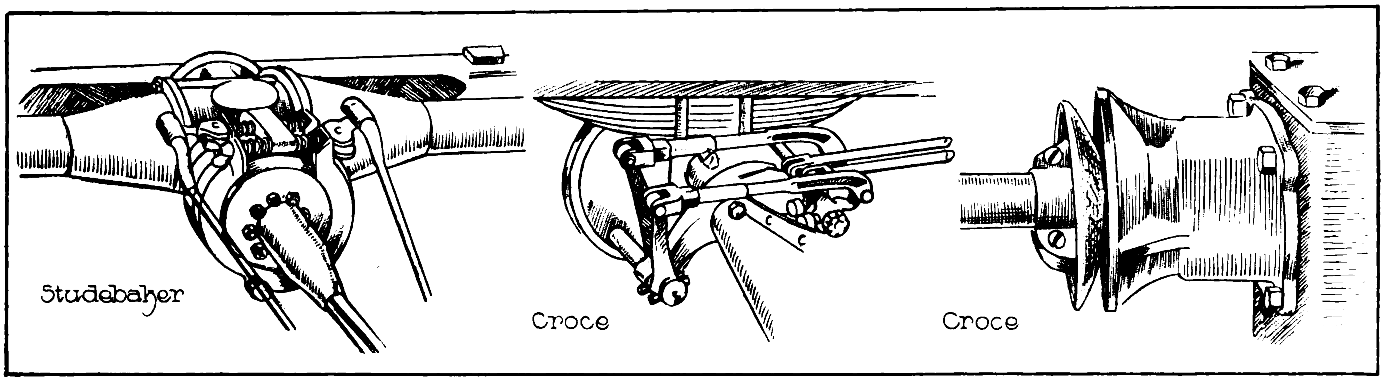
The Pope-Hartford service brake is designed with



Braking Power Greatly in Excess of Needs Afforded in the Light Koehler Wagon and the Packard and Pope-Hartford Truck.



Originality Evidenced by the V Shape Brake Shoe of the Studebaker, the Enclosed Band Brake of the Walter, and the Transmission Brake of the International.



The Double Driving Shaft Brake, a Feature with the Studebaker; the Compounded Linkage and the Clutch, Original with the Croce Machines.

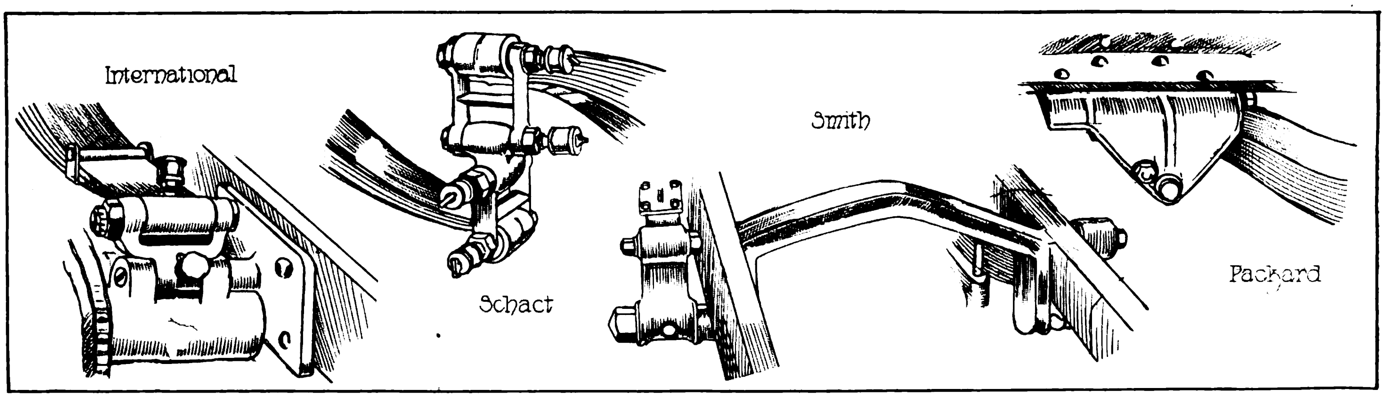
much the same idea, but it differs in the form of the jackshaft hanger extension, which is webbed and drilled to obtain strength and lightness, and the brake shoe is more of the constricting band, being carried on a bolt at the bottom and with the shoes separated by the conventional spring at the top. The shoes are clamped about the drum by the drag of the brake rod and, as with the Packard, they may be easily adjusted and renewed. With both the bolts on which the shoes swing are lubricated by grease cups.

In the Koehler wagon a very ingenious expanding brake is fitted to the rear wheels. The brake drum and sprocket is cast integral and the drum is bolted to the wheel spokes with clips. The spring saddle is a large steel casting that has two arms, the one projecting upward and the other downward, and so curved that they clear the wheel hub. In the ends of these arms are eyes, and a bolt through the lower forms the fulcrum for the brake shoes to swing on, while the other carries a shaft on which is a double cam, and with this cam is formed a lever. The upper ends of the brake shoes are normally drawn from contact with the drum by helical springs, but as the cam is turned it separates the shoes, forcing the shoes apart and against the walls of the drum. This brake has a very large shoe area and it is adjustable by changing the spring tension.

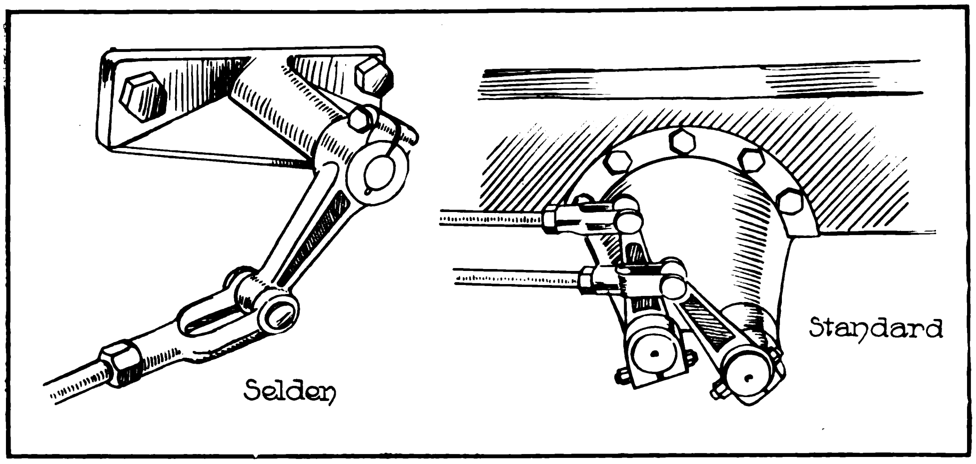
The second emergency brake of the new Studebaker gasoline truck—and it is understood that this design is to be used in the construction of all sizes of these machines—is a decidedly novel application and it is maintained that it is unusually efficient. The truck is driven by concentric gearing and on the periphery of the drum in which the internal gear is cut is a heavy ridge or tongue with sides bevelled so that the top of the tongue is about half the width of the base. The rear ends of the pressed steel radius rods project back of the axle and the lower side of this carries a fitting in which is a shaft, on which swings a long brake shoe in the face of which is a groove shaped as is the tongue, but of such width that the tongue will engage about half the depth of the groove. The shaft has an arm at the other end to which is linked the brake rod, which is carried above the axle. The movement of the emergency brake lever draws the long shoe forward and against the tongue on the drum and both sides of the groove engage. The metal surfaces are given a wedging contact and the braking area is considerable. The construction is such that the wear does not affect the efficiency and the tongue cannot bottom in the groove in the shoe, while adjustment may be quickly made.

A decidedly novel design is that of the service brake on the Walter trucks, where a single drum is mounted on the jackshaft and on this is a contracting band. The drum and band are both large to obtain efficiency and to protect these a casting is bolted to the left side of the combination transmission gearset and differential case, through which the jackshaft passes. The case is very heavy and at the rear is the shaft on which the shoes of the brake swing. As the case is open at front and rear the brake shoes may be easily reached and adjusted.

An unusual application is made in the design of the service brake of the new International delivery wagon in that it has expanding shoes that act on a



Spring Hangers and Shackles Show a Careful Attention to Endurance and Lubrication and Some Very Ingenious Developments.



An Admirable Single Brake Shaft Bracket Is That of the Selden, and the Standard Is Equally Good for a Double Brake Shaft Bracket.

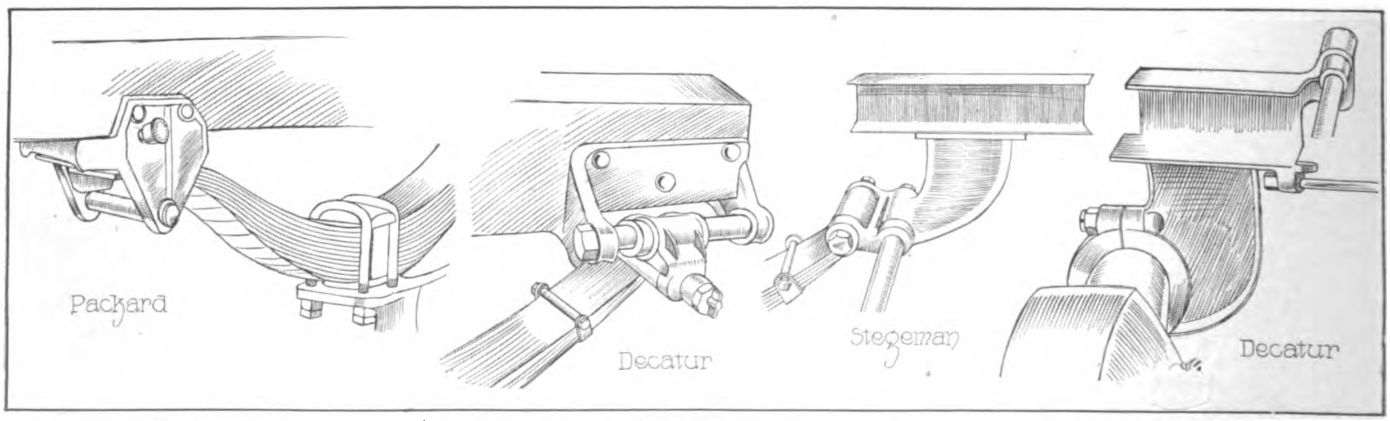
drum carried on the driving shaft, just back of the transmission gearset. The drum is of large size and the shoes have a wide face. On the gearset case is a fitting that carries a transverse shaft that has an arm projecting downward. This shaft is so connected that a forward pull turns a cam between the upper ends of the brake shoes and expands them against the drum.

The first emergency and service brakes of the Studebaker truck are a contracting type and are identical in construction. The two sections of the shoes are hinged at the bottom and the shoes are supported by rods extending through an arm carried forward over the drums, which are on the rear of the driving shaft. One end of the rods is threaded and at the other is an eye. The ends of the brake shoes form ears in which are holes, and the rods support the shoes by these ears, helical springs at either side of the supporting arm separating them. On the threaded ends of the rods are wing nuts by which adjustment is made. Fittings forming cams are pivoted at the eyes at the other ends of the rods, and into these the brake rods are threaded. The draw of the brake rods actuates the cams, drawing the shoes together and clamping the drum. The installation is so made that there is a brake rod at either side of the drive shaft.

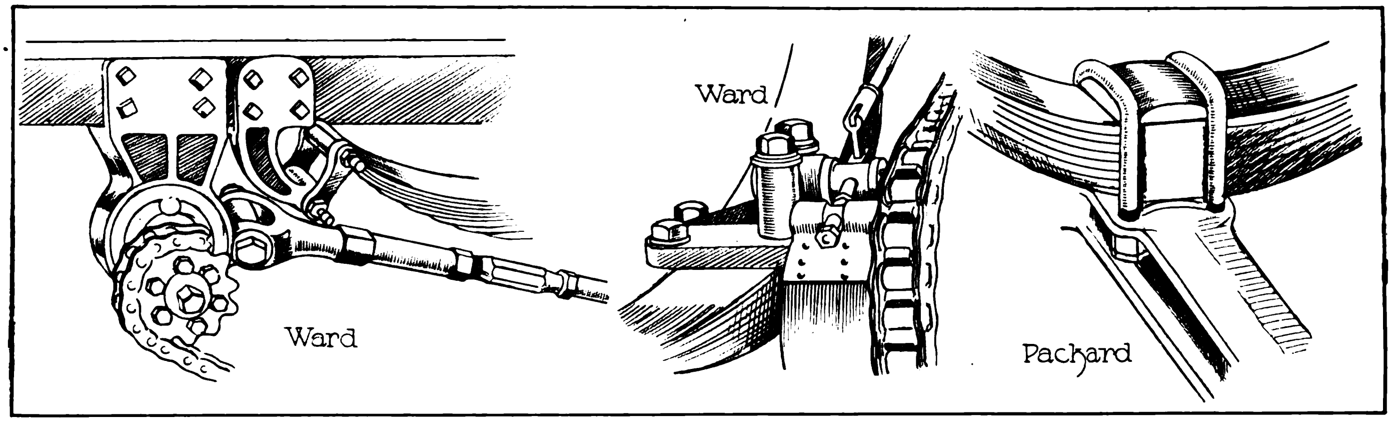
In the Croce wagons and trucks each end of the rear axle carries an arm that projects downward and carries a shaft and sleeve on which are mounted the lever arms to which are connected the rods operating the double set of internal expanding brake shoes. The lever arms are so arranged at either side of the supporting arm and the linkage is such that the braking strain is equalized over the connection. In the 1500-pound wagon a clutch brake of novel design is used. This consists of a conical member faced with asbestos clamped to the shaft that, as the clutch is disengaged, contacts with the faces of a recessed extension of a universal joint housing bolted to the forward side of the transmission gearset case. The joint housing is of bronze. The clutch brake is effective and noiseless, and adjustment may be made by loosening and tightening two screws in the shaft member.

Two interesting examples of brake shaft support are found in the Selden and the Standard machines. To secure straight movement of the brake rods it is necessary to extend the shafts beyond the side members of the chassis frames to such a distance that it is necessary to support them. The Selden design has a substantial member that encloses the shaft and webs strengthen it against any longitudinal stress. This is securely bolted with a long bearing against the frame. The Standard truck member is a semi-circular steel casting of cone shape that carries two brake shafts and it has a wide flange on which it is seated and bolted to the frame.

With springs an interesting shackle is that used on the new International wagon which has a very flat spring that has but little movement with deflection or reflexion. The spring is carried above the hanger and the shackle is a very short yoke, the neck of which is mounted in the hanger. In contrast to this is the double shackle of the Schacht platform suspension which gives practically a universal joint effect, and may yield to any movement, either longitudinally or transversely. The spring hanger of the Smith-Milwaukee truck is a heavy drop forged I section that serves as a frame cross member. This is shaped to give truss effect at the spring ends and it is bolted to the frame with the hangers below it. The shackles



How the Packard and the Decatur Designers Afford a Longitudinal Movement of the Spring Ends, and the Stegeman Engineer Provides Rigidity of the Hangers.



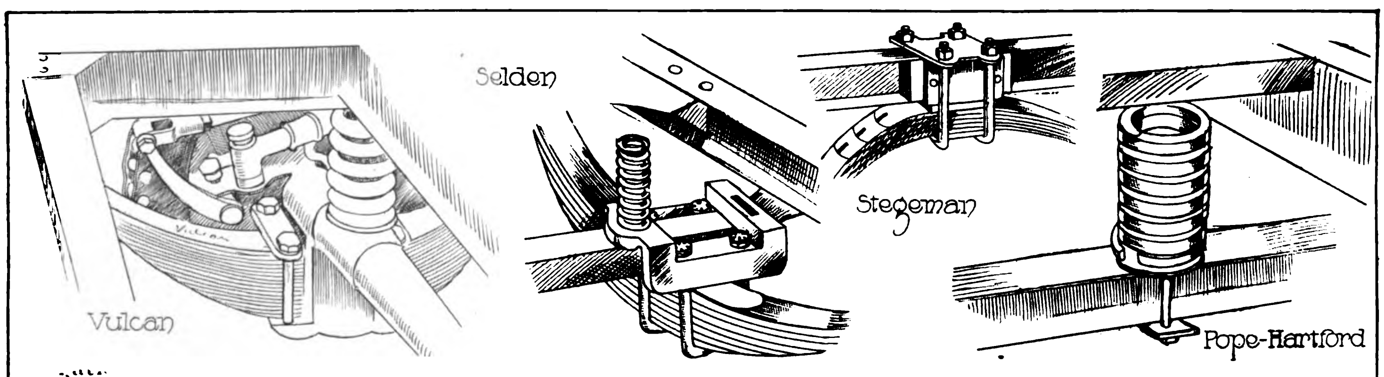
The Forward Radius Rod Connection and the Combination Spring Saddle and Brake Shoe Bracket of the Ward Electric; the New Spring Saddle and I Section Packard Back Axle.

are steel castings of large size and U shaped to insure the greatest strength. One end of the hanger is carried through the shackle end, and at the top a bolt couples the spring and hanger.

The Packard five-ton truck rear springs are mounted in fittings bolted to the frame so that the master leaves contact with the lower webs of the frames. These fittings are cast steel and when assembled the spring ends are free to slide in them as the springs are compressed or recoil. The inside and outside of the frame of this construction are illustrated. With the Decatur delivery wagon the same effect is obtained by mounting the yoke shaped spring shackle on a guide bolted to the outside of the frame, on which movement in either direction is free. The Stegeman design of spring shackle for the rear end of the rear springs is very short and instead of the usual bolt through the shackle and hanger a stout steel rod extends through both shackles and hangers and across the chassis, giving a greater rigidity to the spring hangers and stiffening the frame against varying spring action. In the same group that shows this construction is illustrated the jackshaft hanger of the Decatur delivery wagon, which is fitted to the shape of the chassis frame, and which also carries the support for the emergency brake shaft.

The jackshaft hanger of the Ward electric wagons and the spring hanger for the forward ends of the rear springs are very similar in design, being heavy steel castings bolted to the frame. The radius rod has a forward yoked end that is secured with a bolt to the spring hanger. This rod is adjusted with a turnbuckle fitting. In these machines a clever use is made of the rear spring saddles to carry the brake shoe shaft and the linkage for the brake rod, the saddles being heavily webbed and large bolts being used because of the unusual shape. The spring saddle of the Packard five-ton truck is made with sides that fit the spring its full depth and it has two transverse grooves at either ends into which the U shaped spring clips are fitted and drawn down by nuts below the spring seat, which is forged integral with the big I section axle.

The auxiliary springs of the seven-ton Vulcan truck are helical and are mounted in clamps secured to the big round rear axle. These contact with the frame at the juncture of a cross member when the weight of the load has sufficiently deflected the semi-elliptic springs. The auxiliary springs of the Selden delivery wagon are secured to the spring saddle, which is a drop forged member shaped to the axle with an opening above the axle the width of the spring. The spring clips are tightened by nuts that seat on the saddle at either side of the axle. The auxiliary springs engage with a heavy gusset plate when the side springs have been deflected. The Pope-Hartford auxiliary spring is helical, of square section, carried by a seat that is clamped to the rear axle, and this contacts with the frame when it has been partially loaded. With the Stegeman trucks the jack spring is supported by clips that are secured to a saddle carried on a frame cross member, and this cross member, of channel section, is stiffened under this saddle by a metal block that fills it and prevents buckling under a severe stress.



Auxiliary Springs, Both Helical and Curved, Show Some Interesting Developments for Very Light and Heavy Vehicles.

SIX CENTS A TON-MILE.

Packard Transportation Expert Gives Business Men of Pittsburg Interesting Cost Figures.

Hartley Howard, representative at Pittsburg, Penn., for the Packard Motor Car Company, Detroit, maker of Packard pleasure and commercial vehicles, recently delivered an address to the Manufacturers' and Contractors' Club of that city, in which he discussed the "Automobile vs. the Team." Mr. Howard said that he found but few contractors who could inform him of the cost a mile to deliver a ton of material.

In speaking of his own investigations, for the enlightenment of the business men present, he stated that it cost 12.5 cents a ton-mile to deliver goods by horse drawn vehicles, while with motor trucks it was reduced to 9.5 cents. He also stated that a three or five-ton truck could be operated for from $13.70 to $14 a day. The machine, if kept continually busy, will cover on an average of 40 miles a day, which, Mr. Howard said, would make the cost a ton-mile six cents.

KISSELKARS IN ST. PAUL.

Thirty of These Machines Replaced 145 Horses in Various Lines of Activity.

The Kissel Motor Car Company, Hartford, Wis., maker of KisselKar trucks, has collected some astonishing records of the service of KisselKar machines in various cities. An interesting case is the city of St. Paul, because of its hilly nature and the severity of its winters. In that city there are 30 KisselKar trucks in service, ranging in capacity from 1500 pounds to three tons, no four or five-ton vehicles having yet been sold there. These trucks replaced 145 delivery horses and they travel an aggregate daily mileage of 1566, making 3537 deliveries.

The most significant feature as well as the most gratifying from the standpoint of the truckman is the comparative average of initial investment. The trucks, including several specially designed, represent a total cost of $65,000. The horses replaced, including wagons, harness, blankets, etc., represented an outlay of $62,150. This slight difference in first cost, taken in connection with the ability of the motors to more than double their present mileage if worked a sufficient number of hours, is food for thought.

NEW CALIFORNIA TRUCK.

Holt Motor Company Secures Plant for Its Production in San Leandro.

The Holt Motor Company, San Leandro, Cal., has signified its intention of taking over the building of the Best Manufacturing Company of that place for the purpose of constructing motor trucks. The vehicle is said to be a new one on the market and the outlook for the concern is held to be promising.

The building will be entirely remodelled and expensive machinery will be installed. As soon as the plant is put in suitable condition for manufacturing operations will be begun. H. E. Dorman is to superintend the construction of the trucks. The business offices of the company will be in charge of W. J. Peters.

TWIN CITY CUSTOM MADE.

New Concern in Minneapolis Studies Needs of the Purchaser and Builds Accordingly.

The Brasie Motor Truck Company, Minneapolis, Minn., is a new truck concern recently organized in that city by Frank R. Brasie, who, in addition to being the designer of the vehicle, called the Twin City truck, is owner of the plant and its superintendent. A particular advantage to the purchaser is held to be in the fact that Mr. Brasie makes a personal inspection of each truck in process of construction.

The Twin City truck is not a factory outgrowth, but is built according to the user's needs. The requirements are first learned when an order is received and the vehicle is then constructed. A number of cars produced by the Brasie firm are in service in the Northwest. The factory is located at 2743 Lyndale avenue, South Minneapolis.

STEWART WIDELY DISTRIBUTED.

Used as Far North as Medicine Hat, Alberta, and as Far South as Buenos Aires.

Stewart motor trucks, made by the Stewart Motor Corporation, Buffalo, N. Y., now cover 100 degrees of latitude around the earth, according to figures given out at the Stewart factory. The vehicles are used as far north as Edmonton, Alberta Province, Canada, and the Medicine Hat garage at Medicine Hat, Alberta, has taken the agency. At the other end of the American continent, Pratt & Co., Buenos Aires, is handling Stewart trucks for Argentine Republic.

The first shipment to South America was made recently. Several of the trucks are being operated in Edmonton and a large shipment has been made to Medicine Hat. Stewart trucks are now running in 25 cities.

The Animal Rescue League of Pittsburg, Penn., which some time ago put into operation an automobile dog ambulance of two tons capacity, made by the Lange Motor Truck Company of that city, has given an order for a second Lange machine of the same design. The machine is divided into 34 compartments, thus preventing diseased and healthy anim——ming in contact with each other.

EFFICIENCY OF TRUCKS AS TRACTORS.

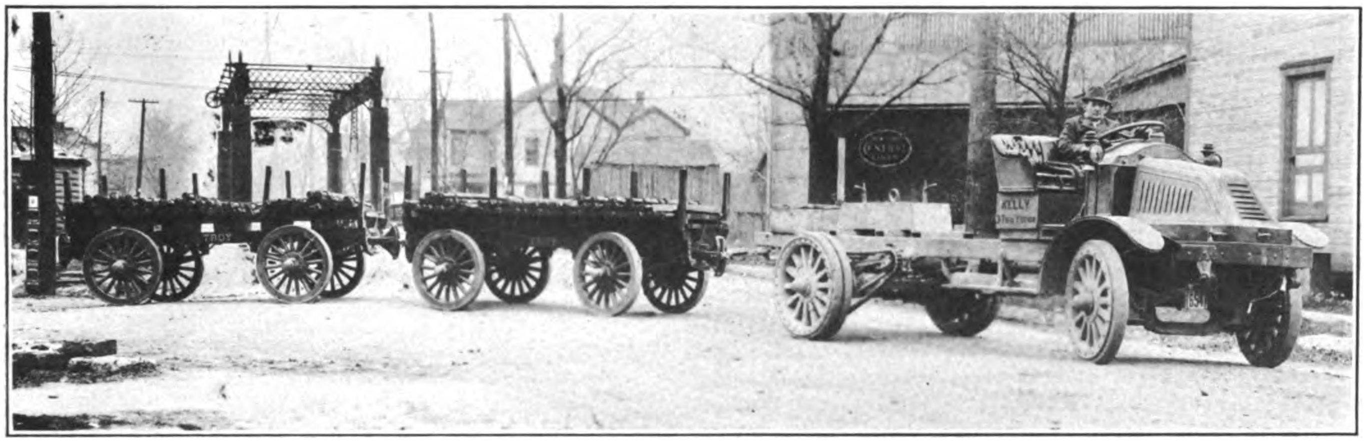
Tests Made by Troy Wagon Works and Kelly-Springfield Motor Truck Companies Indicate Possibilities for Some Services of Well Designed Trailer Trains.

WHILE tractors are an important factor in highway haulage abroad, especially in England, little attention has been given to their use in America. Comparatively few of the English machines are propelled by gasoline engines, for coal, coke, crude oil and similar cheap fuels are used for generating steam, which is the principal power, although several manufacturers install kerosene motors. The greater part of the heavy haulage, that is, loads ranging from five to 10 tons, is with steam trucks or lorries, which are often adapted to draw a trailer, and the traction engines, so-called, are machines which carry no load but have power sufficient to haul several trailers with loads weighing up to 20 tons.

The experience with tractors and traction engines has extended over a considerable length of time, and tests are frequently made which result in careful determinations of efficiency, but these are generally comparisons of similar vehicles and service and have not been, so far as known, with reference to all forms of vehicles. In England upwards of 7000 tractors and traction engines are in use, and the number is constantly increasing, it being generally the experience that the economy is material.

Attention has recently been directed by several American truck and vehicle makers toward the utility of tractors, and some have made very thorough development experiments with a view of ascertaining endurance and perfecting construction. Capacity appears to have been very satisfactorily determined, but comparative economy is little known. The Troy Wagon Works Company, Troy, O., has developed a tractor, which will probably be built in several sizes, and to determine the relative costs of the operation of reversible dump wagons of three yards rated capacity handled in trains and 1.5 yards team dump wagons, an investigation was made by Richard Turner Dana, a member of the American Society of Civil Engineers, director of the Construction Service Company, New York City, at the request of the company.

In this work four road construction contracts of various operations and conditions were studied and curves were plotted showing the haulage costs a ton, in cents up to 3.5 miles. This result is shown in Fig. 1, and considering this it will be noted that large saving is made by the train (indicated by the solid line), as compared with the horse wagons (indicated by the dotted line), in the longer hauls, as, for instance, assuming that a haulage of crushed stone in a six-wagon train (or 40,000 pounds a load) and in a two-horse bottom dump wagon (or 4000 pounds) for two miles, indicate a cost of 20 cents a ton and 46.5 cents a ton respectively. It will be noted, however, that the curves cross at about 1500 feet, beyond which point the economy of the train is apparent. The reason that the curves cross is in the proportion of the lost time to the actual time of hauling. All measures of efficiency are based on delivery, delivery being directly proportional to a combination of the average speed and capacity of the conveyance, and the average speed depending upon the proportion of lost time to the actual time of hauling.

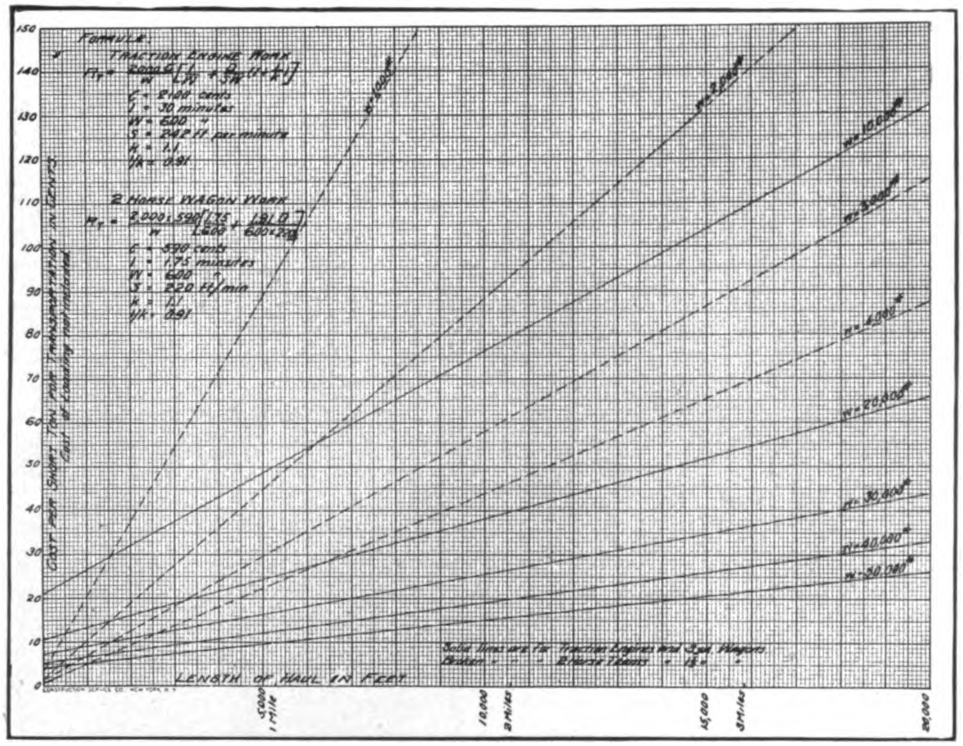


Kelly-Springfield Three-Ton Truck and Trailers Used in Efficiency Tests at Troy, O., for the Troy Wagon Works Company.

Mr. Dana's conclusions were based on very careful observations and well based formulae. The estimates of cost of different vehicles are: One team hauling one slat wagon, $5.8155; one team hauling two rear dump wagons, one of which is loading and one constantly in transit, $6.1025; three-ton motor truck delivering its rated capacity, $8.0866 (total a mile loaded, $0.1537); motor truck serving as a tractor and three trailers, one of which is loading, one unloading and one in transit, $10.7366 (total a mile loaded, $0.2189); motor truck serving solely as a tractor and six trailers, of which two are loading, two unloading and two in transit, $27.8866, including $12 extra labor loading and unloading (total $0.3602 a mile loaded,

and it is pointed out that a satisfactory trailer must stand the stress of higher speeds, with plain, stout, well-lubricated bearings, that will track perfectly with the motor on curves, that is reversible, that can be pushed or drawn at will, and small enough that it can be used easily in trains, so that by its ease in handling the lost time will be reduced to a minimum.

To learn the utility of motor trucks with trailers the Troy Wagon Works Company, in conjunction with the Kelly Motor Truck Company, Springfield, O., made 16 experiments with a Kelly-Springfield three-ton truck and Troy trailers, 10 of these being on city streets preliminary to making others of more definite character. The truck was rated at 35 horsepower, had four speed ratios and a maximum speed of 12 miles an hour. It carried 5000 pounds weight during the tests and with this load weighed 10,200 pounds. One, two and three trailers were used, each weighing approximately 2000 pounds and having a carrying capacity of five tons. During a part of the test the trailers carried four tons, but were later tested fully loaded.

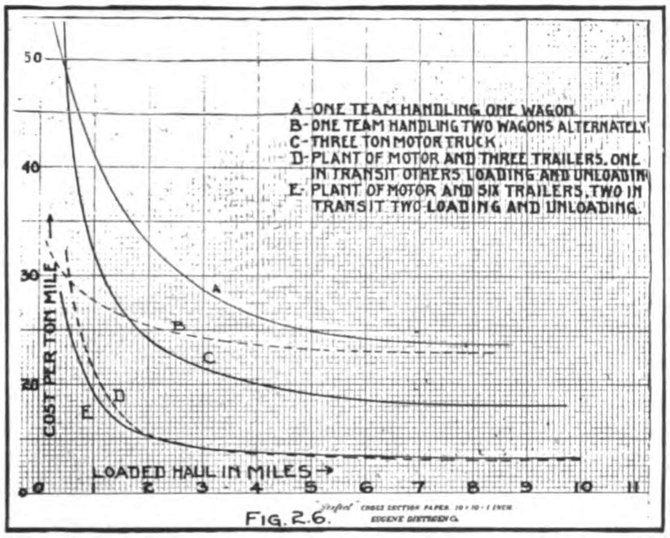


Cost a Ton for Traction Engine Trains and for Animal Vehicles.

The observation was carefully made. The drawbar drafts were recorded every tenth revolution of the trailer wheels, these being read from a Kohlbusch dynamometer mounted in the frame between the truck and the trailers. Time was kept by a stop watch and was recorded at every station from which velocity was determined. The grades of the routes were official. During the test the three trailers were loaded ...th four tons and forward drawbars, locked, rear draw- free, and one man steering the trailer. The train ...ked 400 feet and around a 90-degree cor- ...rated that while it was flexible enough ...l it was rigid enough to resist buckling. This test was made on brick paving and again on macadam with the trailers carrying five tons. For the final experiments a seven-mile course was surveyed, one mile of which was on brick paving and five miles on country macadam road. Marks were well defined for timing, locating the grades, and the different kinds of road. In these final experiments a Kelly-Springfield three-ton truck of 40 horsepower was used, having three speed ratios and a maximum speed of 12 miles an hour. The same dynamometer was used.

Six tests were made as follows: Motor truck and one trailer loaded with five tons of steel; motor truck and two trailers, each loaded with five tons of steel; motor truck and two trailers, each loaded with 2.5 tons; motor truck and two trailers, driven at the same approximate speed as the test when half loaded. Six observers and recorders were carried on the train. The observations noted were the stations, dynamometer, total time, the gear ratio in use and the landmark number, and the reductions included the distance, actual drawbar pull, time interval, velocity and elevation. From these data the reductions were made and the curves plotted, showing the actual drawbar draft, the speed ratios used and the different velocities for the entire route. The motor truck loads were cast iron blocks weighing 2250 pounds each, and on the trailers steel axles weighing 122 pounds each. The live loads included the blocks, axles and men riding, but the driver was regarded a part of the dead weight of the truck. The motor truck dead load was 7980 pounds and the trailers weighed 2080 pounds each.

The first run was of the truck with its rated capacity. The second was with a five-ton load concentrated on a single trailer. The third was to test the maximum draft and tractive capacity of the truck, and on this the motor was stalled four times. The fourth run was with a five-ton load uniformly distributed on the trailers, a comparison of the second run. The fifth run was to test the efficiency of the trailers, but the live load on the truck was reduced from 2.6 to 1.4 tons to observe to what extent the live load of the fourth run caused the stalling of the motor, and the effect of the reduction of the load on the tractive capacity of the truck. There was no loss of traction and the motor climbed one of the hills on which it was stalled. It was concluded that the truck could have been materially lightened and still have capacity to maintain a sustained pull of more than 3000 pounds, and to draw



Relative Cost of Motor Truck and Trains of Trailers.

a dead and live load of 14 tons on good roads and on grades up to 14 per cent. The sixth run with empty trailers was for comparison and the velocity was kept to approximately that of the fifth run. It was concluded that the advisability of small units in trailer trains was demonstrated, for where a train is stalled the lost time may be minimized by breaking up the train and moving the trailers singly over the obstructing grade.

The total load handled and the quantity of gasoline consumed during each run were as follows: First, 7.6 tons, 1.9 gallons; second, 13.7 tons, 1.9 gallons; third, 20.5 tons, 6.1 gallons; fourth, 16.1 tons, 2.2 gallons; fifth, 19.5 tons, five gallons; sixth, 9.7 tons, 4.5 gallons. There is uncertainty as to the fuel consumption for the sixth run. The carburetor of the truck was new and was receiving its first trial, and to this and, possibly, to careless driving, the wide variance may be due. The six runs covered about 42 miles. The result of the tests demonstrated that a three-ton motor truck will maintain a sustained draft of more than 3000 pounds and that on ordinary paving and at average speeds and normal grades the draft required by one trailer with a five-ton load ranged from 400 to 2000 pounds, and from 750 to 3000 pounds for two trailers loaded with five tons each, the variance averaging from 50 to 200 pounds a ton.

The estimates of cost of different vehicles, which have been stated, are applied to the accompanying tabulation.

The accompanying chart demonstrates the facts specified in the above tabulations and indicates the efficiency of the single and two-wagon outfits, the truck alone and used with trailers under different conditions.

Considering these facts, however, it will be noted that the conclusions are based on a series of tests that at best can be regarded nothing more than preliminary. It is stated that there will be a variance in the cost of animal haulage according to the locality conditions, but this is quite as true of the motor trucks and the trailers.

As a matter of fact the expense of using animal teams and wagons is set very low and it is exceedingly probable that it would be materially increased in experience. For instance, in the estimates the horses and driver are hired at $5 a day, but it is evidently assumed that the person doing the work owns the wagons and the harness, for these are separated from the item of horse hire and driver's wages. Depreciation on the wagons and liability insurance (the latter being an item that is not generally carried by horse vehicle owners) and an item of interest are also specified. The estimate evidently comprehends ownership of the motor truck and the trailers.

There is no doubt that a contractor will hire horses and carts, but it is customary to have the price include every charge and the wages of a driver, and this one price covers everything save the matter of tools and superintendence, but only the latter item can be apportioned.

As to the motor truck, it would seem probable that a five-ton machine would be considered rather than one of lesser capacity, because volume of cartage

Ton-Mile Cost of Motor Truck and Trains of Trailers.

means an economy, and the difference in cost of operation is comparatively small. Not only this, but the large truck would be much more serviceable with a train of trailers and it would have more speed than would be desirable in loaded train haulage.

The use of the motor truck that will haul two loaded trailers does not in any way establish the value of the traction engine that will haul six trailers, for instance, for while the truck may be faster it is limited in its capacity, and the traction engine will haul twice the number of tons at a speed of four miles an hour, to illustrate. Not only this, the character of the work, the location, the size of the contract, all are important factors, and it is not possible to apply with any degree of accuracy an arbitrary price. As a matter of fact the cost of the work will vary decidedly, and where the construction is to continue for a considerable period the weather conditions must be considered.

There are specific uses for the tractor or traction engine, just as there are for the motor truck, but these must have weight and power rather than speed, and must be adapted for use on rough ground. If they are to afford service as in England then the machines and the trailers must be easy of handling in traffic and be more adapted for highway haulage than for service on soft and rough ground. It is evident enough that the machine designed for construction work must be of a different type than that built for road transportation, and obviously the efficiency of either would differ according to the work done.

There are many factors to be considered in transportation, and it is evident that to assume a constant for any one of these would be decidedly misleading. It is certain enough that the same factors could be used but each might and probably would have a different value. This application may be made with reference to animals, motor trucks or tractors.

The utility of the tractor and the traction engine is a subject in which there is undoubtedly increasing interest, and the opinions of those who have given the subject study and consideration are of decided importance. These conclusions may be based on facts obtained in this country or abroad, but they are worthy of the attention of all, because they will have a definite value in establishing at least a basis for operation data.

KISSELKARS ON FRUIT FARMS.

California Owners Increase Revenue $20 a Day by Utilizing Motor Vehicles.

Motor vehicles are rapidly being pressed into service in the fruit belts of California and the results have been very apparent to the fruit growers. One example is that of Orlando Moore of Visalia, Cal., who uses a three-ton KisselKar truck, for not only hauling his fruit to market, but for plowing and pulling up tree stumps about the farm. Fruit crops have been prolific in California and owing to the difficulty of getting them to market a large percentage remained on the ground and were lost. These are now saved by the quick delivering motor trucks.

Another man who utilizes a KisselKar truck is F. H. Cavanaugh of Simmler, Cal., which is 28 miles from the nearest railroad station. He formerly hauled his fruit with mules and it required 10 of them three days to make the journey. The trip is now made by the KisselKar in half a day and sometimes two trips are made in a single day. The change has increased Mr. Cavanaugh's revenue from $50 to $70 a day. Some of the little known places in California where motor trucks have been put in service by the fruit growers are Pleasanton, Livermore, Martinez, Le Mesa, San Dimas, Poway and Escondido.

TO PROTECT CREDITORS.

Cleveland-Galion Motor Truck Company Placed in Hands of a Receiver.

Judge Pearson of the common pleas court at Cleveland, O., appointed A. B. Thompson as receiver for the Cleveland-Galion Motor Truck Company, which manufactures the Cleveland-Galion truck. The petition was brought primarily as a measure of protection against hostile interests, it was said.

Elliott Bright, a creditor to the extent of $350, alleged that suits which were about to be filed by other creditors might endanger the stability of the company. President H. W. Woodward of the company concurred in Bright's petition. The offices of the concern are at Cleveland and the plant is located at Galion.

DOG CATCHER USES FEDERAL.

San Francisco Society Employs Wagon to Displace Four Horses at Decided Saving.

In San Francisco, Cal., the Society for the Prevention of Cruelty to Animals has provided for the taking of muzzleless dogs to the public pound. A Federal chassis, made by the Federal Motor Truck Company, Detroit, equipped with a spacious body suitable for carrying the dogs operates daily through the streets of the city. This truck carried three men and the body of the vehicle has 10 divisions to keep the dogs separate.

The machine displaces a wagon with which were employed four horses because of the hilly nature of the streets, two being formerly used in the forenoons and two in the afternoons. The reduction in expense has been a great saving to the society and more than offsets the depreciation in the truck. The latter has been in service six months, covering a total of 6084 miles, or an average of 1000 miles a month at an average cost of $1 a day. It is stated that no mechanical trouble of any kind has been encountered.

THE A B C OF MOTOR TRUCK IGNITION.

Part VII—Outlining the Various Systems Utilized with the Commercial Gasoline Vehicle Their Components and Application in Practise—How Synchronization of the Spark is Secured—Outlining Construction and Operation of the Distributor.

By C. P. Shattuck.

SYNCHRONIZATION of the spark, especially with multi-cylinder motors, makes for greater efficiency in that the time of the explosions and subsequent impulses to the crankshaft are divided evenly, a condition making for a smooth running motor and tending to reduce vibration. By synchronism is meant that the mixture of each cylinder of the multiple unit is not ignited earlier or later than the predetermined instant. The advantage of controlling the time of ignition is obvious. It has been pointed out that theoretically the spark is supposed to occur when the piston has completed its compression stroke and has begun its downward movement or power impulse.

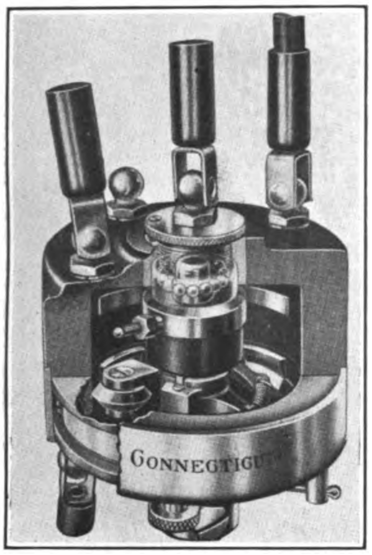

Fig. 29—Showing Components of Connecticut Distributor.

Assume that the point of ignition is top dead centre and that the spark occurs in the first cylinder when the piston is in that position: Expansion of the gases follows and maximum energy is imparted to the crankshaft. If the ignition of the mixture were to take place when the piston had completed part of its downward stroke it is obvious that the impulse would not be as great as if it had taken place at the proper time. This is demonstrated by starting a motor with the spark retarded, then advancing it, when it will be noted that the speed of the motor increases and with the throttle opening unchanged.

To further illustrate the result of irregular time of ignition let it be assumed that the charge in the first cylinder is exploded with the piston at dead centre, the second with the piston an inch down on the firing stroke and the next to fire slightly before dead centre. The results are: A variance in the time of igniting the mixture, more or less efficiency from the expansion of the gases, irregular impulses and the motor subjected to undesirable stresses. Maximum efficiency is not secured from the fuel in that part of the charge passes out with the exhaust without having been converted into useful energy.

Lag in Coils.

It will be seen that it is important that the spark should occur at the proper instant. With the multiple-unit induction coil it is not possible to obtain perfect synchronization of the spark; that is, it does not occur in practise because of a number of existing conditions which will be considered. It has been explained that each unit of the coil acts independently of the others; that the primary circuit is interrupted by a vibrator which comprises a thin strip of metal, and that it remakes the connection between the platinum contact points when the core member loses its magnetism. The time taken by the vibrator member to return to its normal position or contact depends upon its tension, which is adjustable by means of the knurled screw member carrying the fixed platinum contact point, and the flexibility of the metal itself.

Effect of Adjustment.

If the tension of one unit be adjusted to be more or less flexible than another, and if all four differ, it follows that there will be a variation in the time of breaking the primary circuit as well as that of inducing or transforming the current into high-tension. Similarly, the spark in one cylinder will occur earlier than that in another. While it is admitted that the manufacturer of coils synchronizes them and that they reach the user in proper condition, in time the operator will change the adjustment according to the condition of the batteries. Another factor to be considered is the pitting or fusing of the points, a condition that makes for greater resistance. The adjustment of coils requires experience and the various methods and care of the units will be taken up in logical sequence.

Function of Distributor.

Synchronism can be obtained in several ways, either by the use of a master vibrator and a multiple-unit coil, or by a distributor. As the name implies, the distributor distributes the secondary current to each cylinder in proper order. Its principle of operation is similar to that of the timer or commutator in that it is provided with a number of segments, con-

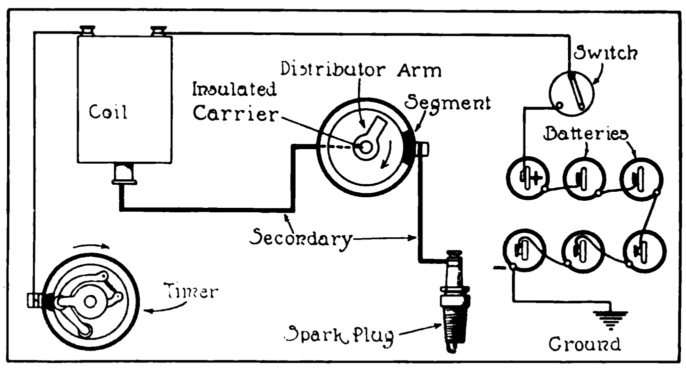

Fig. 30—Illustrating Wiring Plan of Distributor with Primary Section Separated to Outline Circuits.

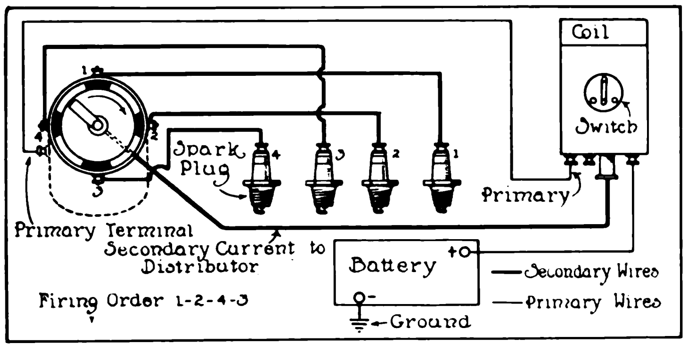

Fig. 31—Wiring Diagram of Four-Cylinder Distributor with Motor Firing, 1, 2, 4, 3.

tact with which is made by a distributor arm, the number of segments equalling that of the cylinders. The distributor may be compared to a double timer, the one caring for the primary current, the other the secondary or high-tension.

Construction of Distributor..

Distributors vary in design, but their principles of operation are similar. At Fig. 29 is presented a conventional type with a section cut away to show the components, and it will be noted that it is composed of two principal parts, the primary and secondary, which are held together by two threaded studs having spring tension lock nuts, a construction making easy disassembly or cleaning. The primary section is similar to the ordinary timer and the unit illustrated is utilized with a four-cylinder motor.

The timer and distributor sections are separated by a hard fibre disc, this being employed to prevent lubricant working from the timer into the distributor and thereby creating trouble. The upper section is composed of a fine grade of hard rubber, accurately machined and polished, and the walls are substantial to prevent warping or distortion when exposed to high temperatures. The construction is dust and water proof.

Mounted upon the shaft extending from the timer section is a key retained hard rubber cap to which is secured and from which extends the metal distributor arm insulated from the metal shaft, but in contact with a stud or terminal member. On the inside of the rubber case and in line with the distributor arm are mounted slightly projecting contact blocks spaced in synchronism with the contact maker in the lower section, and secured in a manner similar to the contact blocks of the timer.

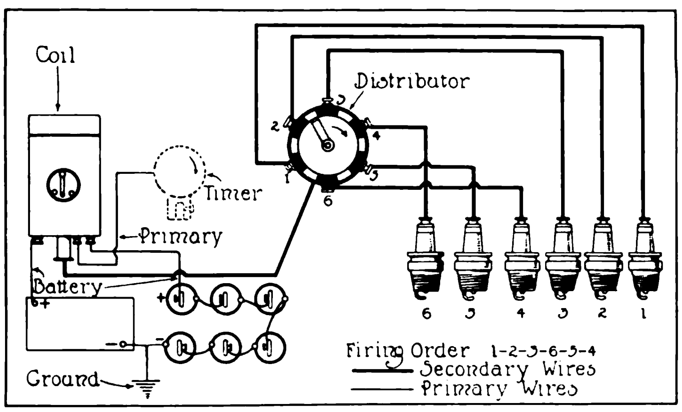

Fig. 32—Six-Cylinder Wiring Plan—Primary Section of Distributor Is Indicated by Dotted Lines.

Operation of Distributor.

The distributor replaces the usual timer and is mounted upon a shaft which rotates at camshaft speed. Its operation is as follows: The primary current is led from the storage battery, dry cells or other source in the same manner as with the ordinary timer; that is, one wire is grounded and the second is led through the switch, thence to the primary connection of the coil. When the roller makes contact with the block in the timer section of the distributor, the circuit is closed and the low-tension current is transformed into high by the coil. It passes from the coil through the secondary wire or cable to the insulated distributor arm in the distributor section and when this arm comes opposite the metallic plate or segment, the high-tension current jumps across to the segment, passing out through the insulated terminal, thence proceeding to the spark plug by the conventional lead.

The circuits and components are depicted at Fig. 30, the timer and distributor members being drawn separately to make clear the flow of the primary current, its interruption and the method by which the high-tension electricity is led to the distributor arm. The wiring plan is that utilized with a single-cylinder motor, but the high-tension current may be distributed to any number of cylinders, the construction involving a segment for each.

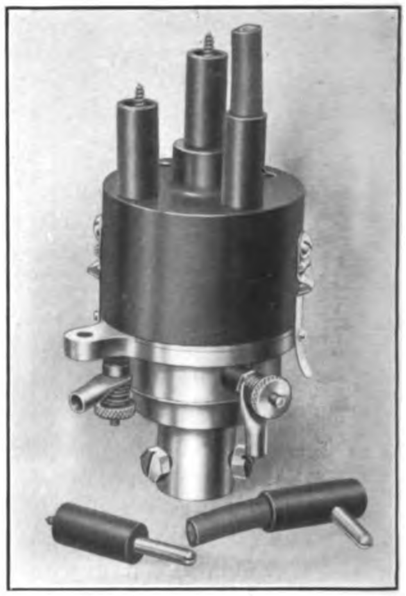

Fig. 33—Connecticut Igniter Distributor.

Requirements of Design.

The requirements of design are such that the primary and secondary sections of the distributor must be separated in such manner that lubricant cannot find its way into the high-tension compartment, for it is well known that particles of metal or carbon mixed with oil form an excellent conductor of electricity. It is also imperative that other foreign matter be eliminated. The distributor proper does not need lubrication as there is no friction except at the shaft bearings and these are contained within the primary section. The distributor arm does not make contact with the metal segments as it does in the primary section or a timer, there being a very small space between the end of the arm and metal segments. This creates a gap which is held to be beneficial.

The advantages of a distributor are: Synchronization of time of spark, compactness and the elimination

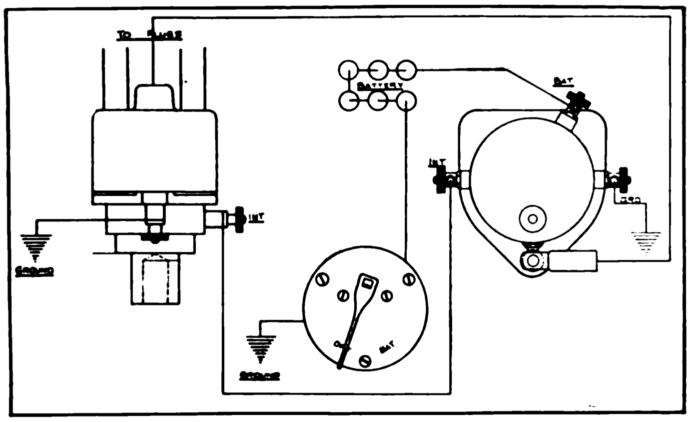

Fig. 34—Wiring Plan of Connecticut Igniter Distributor and Coil System.

of multiple coils and wires when utilized with a power plant of two or more cylinders. But one induction coil is necessary, and with a vibrating unit employed the alteration of the tension of the vibrator member does not affect the time of the spark when multiple cylinders are involved. Even with the platinum contact points pitted the resistance is the same, irrespective of the cylinder to be fired. Lag is eliminated in that when the motor is running at high speed the vibrator is practically in constant motion and this increases motor speed as there is no time lost after energizing the primary coil by setting in motion the vibrator. In place of the four or six primary timer leads, but one is employed, this conveying the primary current.

Four-Unit Distributor.

At Fig. 31 is shown the wiring plan of four-cylinder distributor and with the motor firing 1, 2, 4, 3. The method of the distributor is practically the same as with the ordinary timer, the piston of the first cylinder being brought to the top of its compression stroke and allowed to descend slightly on the firing, with the distributor arm opposite a segment, the No. 1 for example. Provision is made for securing the distributor to the shaft and locking it as with the usual commutator.

The wiring is simple. One lead of the battery is grounded to the frame or other metal part of the chassis and the positive wire secured to the "battery" terminal on the coil. From the coil is led a primary wire to the primary terminal on the lower section of the distributor, this being denoted in the drawing by dotted lines.

The one secondary wire from the coil is then secured to the terminal or post on top of the distributor. With the shaft rotating clockwise, the high-tension cables from the high-tension terminals on the distributor are connected to the spark plugs in the same manner as with a four-unit coil; that is, the first and second segments are wired to the first and second cylinders while the third and fourth terminals are connected to the fourth and third cylinders respectively. If the driving shaft rotates anti-clockwise, the leads will have to be reversed and the connections made according to the order of firing of the motor, which may be 1, 3, 4, 2 instead of 1, 2, 4, 3. A little study of the wiring diagram should enable the reader to wire the distributor properly.

At Fig. 32 is shown the wiring plan for a six-cylinder distributor and it will be seen that there are six segments, one for each unit. In this instance there are two independent sources of current, a set of dry cells and a storage battery, but both are grounded by splicing the negative lead of both batteries and securing the wire to a metal part of the chassis. The positive wire from the dry cells is secured to the right hand battery terminal on the coil and the lead from the storage carried to the other post on the coil.

As in Fig. 31 the primary section of the distributor is indicated by dotted lines and the primary wire is connected to this member. The firing order of the power plant in this instance is 1, 2, 3, 6, 5, 4, and the connections between the segments and the spark plugs are made in this order. As previously pointed out, any number of segments may be utilized, depending upon the number of cylinders.

Igniter Distributor.

Synchronization of the spark may be obtained by a master vibrator or by an igniter distributor. With the latter system the igniter member is operated from the camshaft. With four-cycle motors it is driven at one-half engine speed and at crankshaft speed with two-cycle engines. Like the distributor previously described it must be actuated by a gear driven shaft. It is provided with a primary circuit breaker mechanism, making for synchronism, and the device is fitted with cams which actuate the circuit breaker and strike the roller of the breaker arm, thus making and breaking the primary circuit successively. The breaker mechanism consists of a light steel lever pivoted on a steel stud, a bone fibre roller bearing against the cams, and a platinum contact held against a platinum tipped contact screw by a steel spring. The screw member is insulated and is accessible for adjustment, cleaning, etc.

The distributor arm is secured to the shaft and carbon brushes are employed to make contacts with the distributor blocks and secondary coil terminal. The operation of this member in distributing the high-tension current is similar to the system previously de-

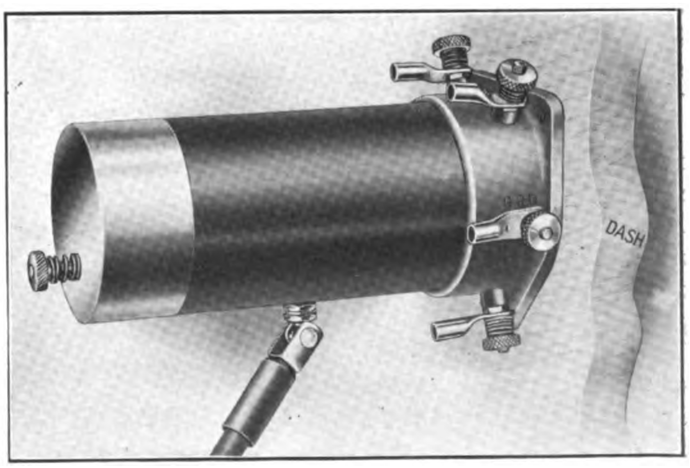

Fig. 35—Dash Coil Employed with Connecticut Igniter Distributor.

scribed, but the construction differs in that contact is made between the arm member and segments instead of utilizing a gap. In many respects the igniter is similar to the magneto in the method utilized for breaking or interrupting the primary current and distributing the secondary or high-tension electricity. With the igniter system a dash coil is employed, and a back view of one of these members is shown at Fig. 35. The igniter is depicted at Fig. 33 and the wiring plan at Fig. 34.

With either of the high-tension distributor systems outlined the time of spark may be changed; that is, it may be made to occur earlier in the combustion chamber as with the timer and multiple coils. This advance of the time of spark is brought about by moving the housing or casing of the distributor in the direction opposite to that in which the arm is rotating, bringing about an earlier closing of the primary circuit and building up the secondary current. This advancing of the spark as it is termed is brought about by suitable connections between the control lever on the steering wheel and the distributor housing.

(To Be Continued.)

Ed. Note—The next installment will deal with the master vibrator, explaining its construction and operation.

TO MANUFACTURE STEEL BAR.

New Concern Organized at Canal Dover, O., to Produce Material for Automobile Work.

A new concern, capitalized at $1,200,000, to be known as the Dover Superior Steel Company, has closed negotiations to locate its plant at Canal Dover, O., and will employ 600 men. The promoters of the company are all well known and practical steel men of Pittsburg, Penn., including W. M. Parkin, H. T. Myer, Archie Smith and M. S. Young.

The concern is to manufacture steel bar for automobile chassis and steel furniture. The metal will be received at its plant direct from the Canal Dover furnace and in its molten state. Thirty-five acres of ground adjoining the furnaces have been secured for the erection of the plant.

The San Francisco Motor Truck Association is the name of an organization of the motor truck men of that city, formed recently at a well attended meeting of the local representatives. There was considerable enthusiasm displayed and it was the general belief that there was a very wide field for the activities of such an association. Officers were elected as follows: President, Charles B. Lewis, Lewis Motor Truck Company; vice president, C. E. Osborn, Speedwell Motor Car Company; secretary-treasurer, Harold D. Knudson, J. W. Leavitt & Co. A committee of five, with President Lewis as chairman, was appointed for the purpose of drafting a constitution and bylaws and to gather data from eastern truck associations.

INTERESTING LAFRANCE TEST.

Demonstrates Value of Hydraulic Transmission as Well as Saving in Time and Traffic Space.

A LaFrance hydraulic truck, made by the La-France Fire Engine Company, Elmira, N. Y., recently gave a demonstration at New York City, when it hauled 45 tons over a route approximately four miles long. This performance is interesting as showing not only the capabilities of motor traction, but also exhibiting the possibilities of hydraulic transmission. It is claimed that no power in mechanics has yet been found to exceed hydraulic power and while the concerns now making use of the Manly transmission idea have not made the progress that will probably result later, the feature is being watched keenly by the motor truck interests.

In the test mentioned, 45 tons were hauled from the New York city hall to 67th street and the East Side. The truck itself, weighing 4.5 tons, was loaded with six tons of boiler fittings, while behind was attached a wagon weighing 12.5 tons and carrying a boiler weighing 22 tons. At least 20 horses would have been required to haul this load. They would have occupied at least 250 feet on the streets and would have effectively blocked all traffic while they were passing.

The LaFrance truck was only 20 feet long, so that there was over 230 feet of street space saved. Further, the run was made with the truck in half the time that horses would have taken, which means that the streets were in use only half as long. Thus the test proves that the hauling of heavy materials through the streets of big cities by heavy motor trucks, either with or without trailers is of advantage not only to the owners of the trucks, but to the people who use the streets.

COMPETING WITH RAILROAD.

KisselKar Operating with Success in This Field in Southwestern Connecticut.

The motor truck in interurban traffic is becoming a most formidable competitor of the railroad. Instances of large industries that are now using the truck in short cross country runs are numerous, a recent and typical case being that of the Weidman Brewing Company of New Haven, Conn.

This company employs two four-ton KisselKar trucks, made by the Kissel Motor Car Company, Hartford, Wis., between New Haven and the neighboring cities of Bridgeport, and Ansonia, whereas the railroads were formerly relied upon for deliveries to customers at these points. The machines carry their cargoes directly to the door of the patron, while under the old method two additional handlings were necessary. Each truck makes 75 miles daily with 12 to 14 deliveries.

Municipal Service Equipment

G. M. C. HORSE AMBULANCE.

Detroit and New Orleans Only Cities That Have Installed Vehicles of This Type.

Citizens of Detroit are grateful to Miss Stella Fors for her gift of a new motor horse ambulance to the city. There is only one other car similar to it in the entire country and that is owned by the Society for Prevention of Cruelty to Animals at New Orleans, La. Both machines were made by the General Motors Truck Company, Pontiac, Mich.

Across the blue panelling in police colors is printed "Animal Welfare Ambulance." The car is provided with a movable floor, which slides on rollers under a stricken animal to lift it into the body of the car. If an animal is able to walk its ascent into the ambulance is an easy, gradual one, and to prevent the necessity of backing it out a side door is provided for the exit.

FULFILLS ALL EXPECTATIONS.

Fire Commissioners in Springfield, Mass., Well Satisfield with Present Equipment and Will Add More.

The annual report of the fire commissioners and Chief Daggett of Springfield, Mass., devoted much space to the consideration of motor driven fire vehicles. The department now has but a few pieces of horse drawn apparatus in service and it is recommended that these be replaced by motor fire machines. The fire commissioners expressed gratification that the introduction of motor driven apparatus has effected a saving to the city commensurate with the original estimates when the subject of such equipment was first considered locally and concluded with the following:

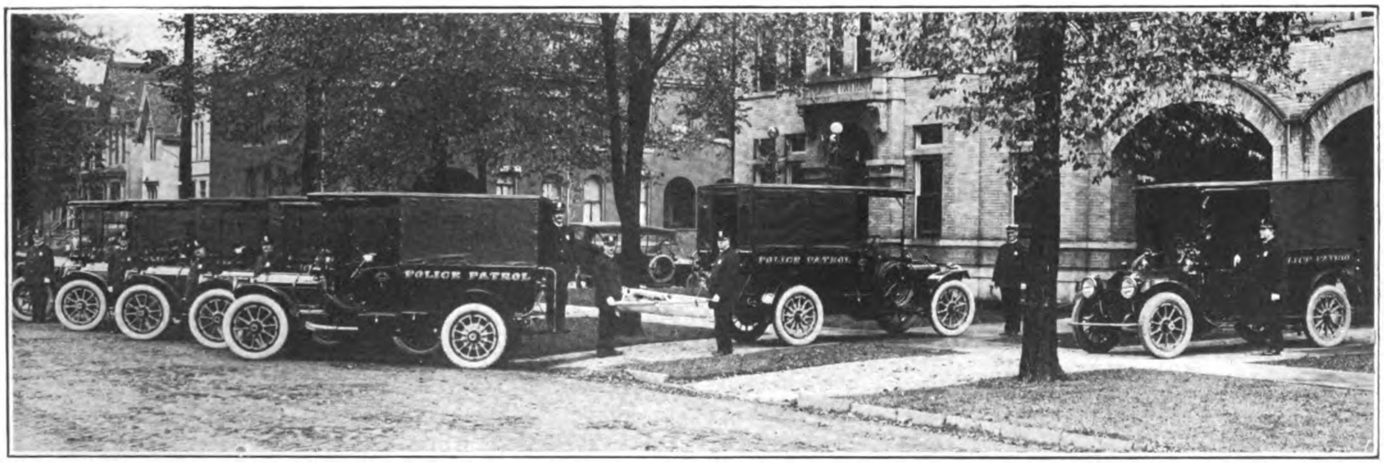
"Of the motor fire apparatus now in service there is nothing to be said except that it has given complete satisfaction throughout the year. As so-called comparisons of the cost of maintenance between motor and horse apparatus are so overwhelmingly in favor of the motor pieces, no attempt has been made to present such a statement herewith."

PACKARDS IN POLICE SERVICE.

Detroit Department Finds Each Is More Efficient Than Three Horse Patrols.

An accompanying illustration presents a portion of the Packard patrols, made by the Packard Motor Car Company, Detroit, and in service with the police department in that city. These machines have been in use nearly two years and others have been added since this photograph was taken. Practically all of the emergency ambulance calls in the city are handled by these cars, and the number of sick and injured carried in a year is approximately 3000 persons, in addition to the ordinary calls of a police patrol.

According to Fire Commissioner Frank H. Croul, these seven vehicles cost the department $6481.73 for



Seven Combination Ambulances and Patrol Wagons, Made by Packard Motor Car Company and in Service with Police Department in Detroit.

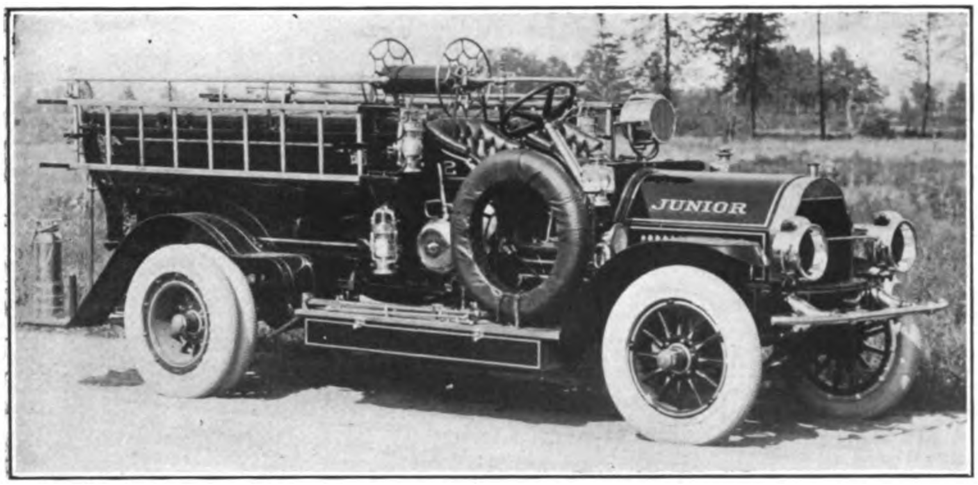
one year, this sum being divided as follows: Tires and tire repairs, $3760.74; miscellaneous repairs and painting, $968.20; gasoline, $1487.58; lubricants, $265.21. They responded to a total of 32,939 calls and covered 81,599 miles.

"One motor car with two men," says Mr. Croul, "will cover as much territory as three horse drawn wagons with six men and give vastly better service. We have worked out a dovetail dispatching system by which the cars may be shifted rapidly as the need of the hour demands. The largest factor of saving is the reduction in the number of men. I wouldn't care to handle this department any longer if I had to give up the motor patrols. Every horse has been eliminated."

KNOX FOR SMALL TOWNS.

Type of Combination Fire Fighting Apparatus That Has Enjoyed Wide Popularity.

Herewith is illustrated a Knox model M-3 combination hose and chemical wagon, made by the Knox Automobile Company, Springfield, Mass. This is a type of vehicle which has enjoyed wide popularity in small towns and in cities for covering outlying districts, etc. It has a maximum road speed on pneumatic tires of 40 miles an hour, or 30 miles on solid tire equipment.



Knox Model M-3 Combination Hose and Chemical Wagon, Fitted with 50 Horsepower, Four-Cylinder Motor.

The wheelbase is 145 inches and tread 60. The motor is a Knox four-cylinder model M rated at 50 horsepower, with bore and stroke of 5.5 inches. The transmission is of the special heavy selective type, affording three forward speeds and reverse. Final drive is by double side chains to the rear wheels. The approximate weight of the chassis is 6000 pounds, and two types of body are fitted. One is with one 35-gallon chemical tank, like that in the illustration, which is eight feet five inches long by 50 inches wide. The other has two tanks of the same capacity, and is seven feet by 50 inches.

The equipment includes 200 feet of chemical hose with basket or reel, two three-gallon hand extinguishers, acid bottles, soda bags, roof ladder, extension ladder, siren, locomotive bell, horn, headlights, searchlight, side and rear lamps, Prest-O-Lite tank (all lights electrically ignited from switch on dash), speedometer, firemen's lanterns, axes, crowbars, tools, extra parts, etc. It has capacity for 800 to 1000 feet of regulation 2.5-inch fire hose and 10 to 12 men.

MARSHALLTOWN COMPARES COSTS.

KisselKar Maintenance a Month Less Than Average Upkeep of Horses a Fire.

Chief I. T. Kirby of the fire department of Marshalltown, Ia., has submitted to his city government a report comparing the cost and efficiency of a KisselKar hose and chemical wagon with the horse drawn vehicle which it replaced. Chief Kirby, in his report, shows that during the period between April 1 and Dec. 1, 1912, there were 69 alarms. Comparing the cost of maintenance during the eight months of the previous year he presents the following figures:

Cost of maintaining team, eight months, including feed, shoeing, harness and veterinary service, $331.36; cost of maintaining automobile, eight months, including gasoline, oil, Prest-O-Lite and repairs, $25.17; cost of maintaining automobile, a month, $2.09; cost of maintaining team, a month, $41.42; cost of maintaining automobile, a fire, 36 cents; cost of maintaining team, a fire, $4.80; balance in favor of automobile, a fire, $4.44; balance in favor of automobile, a month, $39.33; balance in favor of automobile, a year, $471.96.

These figures are of particular interest as indicating in no uncertain terms the economy effected by utilizng automobile equipment.

NEWS OF GENERAL INTEREST.

No Horses in Five Years—Within five years not a single horse will be in use by the fire department in Cleveland, O., is the prediction of Safety Director C. W. Stage. The work of motorization is now under way and $45,000 will be expended for additional apparatus. Eight motor vehicles are to be purchased for the fire department and the police department is authorized in a separate appropriation to secure four automobile patrol wagons. Two flying squadrons will be equipped out of the $45,000 appropriation and new companies will be established.

Saves Dollar a Day—Fire Chief Chase of Northampton, Mass., in his recent report relative to the motor fire apparatus in use in that city, states that during the six months it has been in service the cost of

maintenance has been $5 a month and compares this with a cost of $36 a month for maintaining a pair of horses. The complete report of Chief Chase brings the question closely to the point of asking whether the city can afford to maintain any horse drawn apparatus in its engine houses. So impressive have the figures proved that the neighboring town of Easthampton, Mass., will probably consider at the coming annual town meeting the installation of automobile fire apparatus.

Meriden Would Replace Horses—The tax board of Meriden, Conn., has voted to motorize the fire department of that city. For some time the fire department has had in use a big Webb motor fire engine, made by the Webb Company, Allentown, Penn., and although it was more or less of an experiment, it has been successful in spite of careless handling, hard usage and other adverse conditions. It was its demonstration of quick and efficient service that led the tax board to declare in favor of a motorized fire department.

KisselKars in Milwaukee—Two new KisselKar patrol wagons, built by the Kissel Motor Car Company, Hartford, Wis., have been placed in commission by the city of Milwaukee, Wis. These make a total of five KisselKars in the service of that city. Two others are used in the water department and one does the runabout business of the public library. The new patrol bodies surmount regular two-ton truck chassis with the exception that the motor is the Kissel six-cylinder, instead of the four-cylinder type commonly used.

Springfield Police Purchase Car—The police commission of Springfield, Mass., has purchased a touring car, made by the Knox Automobile Company of that city, for the use of the chief of police and members of the detective bureau. A new patrol wagon for the department is being built along special plans by the Knox company. In negotiating for this the police department saved $500 out of its appropriation for the purpose and a considerable surplus was shown over the annual appropriation of the department. Permission was obtained to use this money for the police touring car, the need of which has been felt in police work for some time.

Augusta Wants New Apparatus—Chief Frank G. Reynolds of the fire department in Augusta, Me., in his annual report praises the work done by the motor driven fire apparatus and recommends the replacement of some of the present horse drawn vehicles by automobiles, also a new fire station in the hill section of the city, to have two motor wagons in service. The apparatus recommended for the new hill station are a modern motor pumping engine to carry 1000 feet of 2.5-inch hose and all necessary equipment; and a combination truck to carry a 50-foot extension ladder, 60-gallon chemical tank, 250 feet of chemical hose, hand extinguishers and a full equipment of ladders ranging from a 12-foot scaling roof ladder to the 50-foot extension.

Abbott-Detroits for Denver—The city of Denver, Col., has placed an order with the Abbott Motor Company, Detroit, maker of Abbott-Detroit machines, for four 34-40 three-passenger roadsters for use by assistant fire chiefs. The cars are to be painted pure white with gold stripes and red wheels and no time is being lost in filling the order.

White Machine for Malden—A new White fire truck, known as Combination B, made by the White Company, Cleveland, O., has been put in commission by the city of Malden, Mass. This apparatus is mounted on the standard White 40-horsepower fire truck chassis and is equipped with the very latest mechanical aids to effective fire fighting. It has an electric starter and electric lights, is shaft driven and has the centre control with left-hand drive.

Buffalo Adds to Equipment—Plans are being considered by the fire commissioners of Buffalo, N. Y., for the substitution of motor driven apparatus for the old horse drawn machines, including automobile runabouts for use of the battalion chiefs. Reliability and efficiency as shown by the motor engines have solidly established them as factors in the fire fighting service of Buffalo. The first big truck to be placed in action will probably be of the 85-foot extension type for use in the business district and at least one to be added soon will be of the gasoline pumping type. Still another machine will be a gasoline driven steam pumping engine.

Webb Combination for Lynn—The city of Lynn recently accepted for service a new $9000 combination pump and hose wagon, built by the Webb Company, Allentown, Penn. It is the latest type on the market and weighs eight tons. It is equipped with a six-cylinder, 90 horsepower engine capable of driving it at a rate of 60 miles an hour, fully equipped and with a crew of 16 men besides the driver.

Kelly-Springfield for Fire and Police—The city of Springfield, O., has awarded to the Kelly-Springfield Motor Truck Company the contract for two automobile hose trucks for the fire department and one automobile police patrol as well.

In the Market—Among the cities in the market for the purchase of motor apparatus are the following: Alameda, Cal.; Providence, R. I.; Temple, Tex.; Marlboro, Mass.; Evanston, Ill.; Rumford, Me.; Needham, Mass.; East Liverpool, O.; Monongahela, Penn.; Appleton, Wis.; Harrisburg, Penn.; Akron, O.; Chelsea, Mass.; Franklin, Penn.; Des Moines, Ia.; Roseburg, Ore.; Cosmopolis, Wash.; Attleboro, Mass.; Michigan City, Ind.; Stockton, Cal.; Morristown, N. J.; Aurora, Ill.; Madison, Wis.; Racine, Wis.; Oshkosh Wis.

New Commercial Car Accessories

Gilmer Endless Belt.

The L. H. Gilmer Company, 52 North Seventh street, Philadelphia, is manufacturing the Gilmer endless belt, which is constructed especially for model T Ford automobiles. It is woven of a material which is held to be water and oil proof and a quality claimed for it is that it will not stretch after considerable service. The maker holds that it will grip the pulleys even when loose and that it is not necessary to adjust it tightly. It is also pointed out that it will give maximum service when allowed to run slightly slack on the pulleys. The Gilmer woven endless belt is inexpensive.

J-M Keystone Radiator Shield.

The J-M Keystone radiator shield is the product of the H. W. Johns-Manville Company, New York City, and is applicable to both pleasure and commercial vehicles. It not only protects the radiator by preventing freezing of the water, but makes for easier starting as the heat is retained for a considerable period. It consists of a neat, thick, quilted pad, formed by a layer of thoroughly cleansed cattle hair which is held to be one of the best known insulators against cold. This is stitched securely between water proofed imitation leather and the entire design fits snugly against the radiator. It is provided with an adjustable flap which permits of entirely closing the cover when operating the car in extreme cold weather. On mild days the flap may be opened, thereby securing ample radiation. A quality of the cover is that it may be easily and quickly fitted or detached, and its compactness enables folding and placing under the seat when its use is not desired. It is made in three sizes, these being 26 by 27 inches, 22 by 23 and 20 by 21.

Perfect Gasoline Filter.

A gasoline filter that differs from those of conventional practise is that manufactured by the Gasoline Filter Company, 145 West 45th street, New York City. Although the filtering element is chamois, it is arranged in the form of a bellows to a free end of which is attached a small rod extending through the filter casing. The other end of the chamois being fixed, it follows that movements of the rod alternately compress and extend the bellows, expelling all fluid from their interior. This cleans the filter material much in the same manner as one would rinse a cloth. The fuel enters the lower inlet and passes through the fine chamois to an outlet to the carburetor. All foreign elements, including water, fall to a reservoir fitted with a drain cock. The filter is easily incorporated in the main line as compression screw attachments are utilized in place of the usual soldered connections. A quality of the device is the fitting of an air vent at the top of the housing, and by removing the screw after installation any air in the line may be expelled. The essential tools in fitting the filter are a hacksaw and a small wrench. It is neatly finished in nickel, very compact and moderately priced.

Vim Motor Starter.

The Vim Manufacturing Company, Cleveland, O., is marketing a motor starter of the acetylene type. The cylinders of the engine are primed with the proper proportions of gas and air and the mixture is ignited by a spark in the conventional manner. The acetylene is led from the tank to the dash, thence to the intake manifold of the motor. The control unit is of special construction and is held by the maker to be highly efficient. It is not only easily operated from the seat, but the maker claims that it is impossible for any acetylene to escape. The dash device is very neat, comprising a numbered dial and a lever. By moving the latter to the proper number the desired mixture is secured. The Vim motor starter is very compact, weighs slightly over a pound and the maker states it may be fitted in 30 minutes and without the aid of special tools.

Dover Safety Fuel Can.

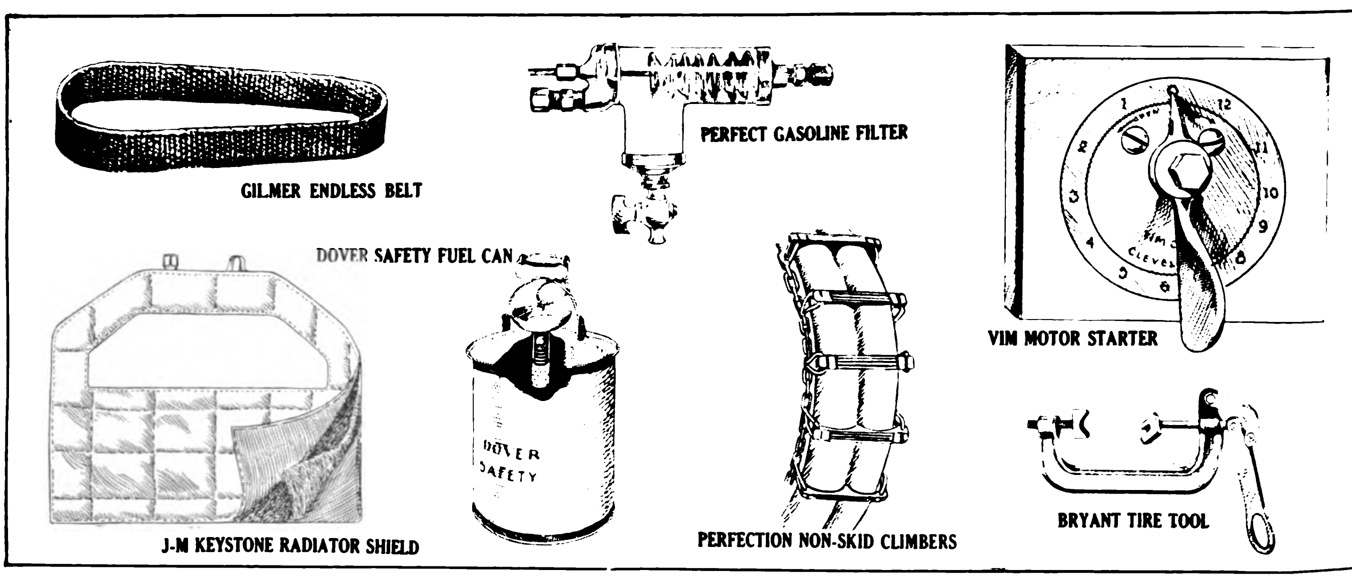
Among the new products of the Dover Stamping & Manufacturing Company, Cambridge, Mass., is the Dover safety gasoline can. One of the interesting and practical features is the self-closing attachment which not only prevents evaporation of the fuel, but eliminates opportunity of explosions. The device comprises a large brass ball ground into a valve and normally held closed by a spring. The valve member is surrounded by a gauze chamber, preventing fire reaching the vapor of contents of the can when pouring or filling. In the five-gallon size the valve opens and closes automatically when pouring, but cannot open accidentally. On the one-gallon and one-quart sizes the valve is held open by a slight pressure of the thumb, closing when released. The cans are constructed of heavy galvanized steel, painted red and stencilled "Gasoline." Economy of fuel is effected by air tight qualities. The containers are moderately priced.

Bryant Tire Tool.

Stevens & Co., 375 Broadway, New York City, is marketing the Bryant tire tool which presents a number of practical features in that it may be employed for removing rims as well as the shoes. It is universal in that it will fit all styles and sizes of rims, and will remove and replace them with little exertion. It is fitted with tire and rim engaging devices, one carried by a slide shaft and the other on an adjustable screw, the latter being adapted for tires from four to six inches. The slide shaft passes through a guide hole and forces the wedge member downward into the bead, and it is held that it will not ride upward and injure the thin wall of the casing. Considerable leverage is secured through the construction of the tool which, after forcing back the ring member, locks automatically. This is of considerable value in that it enables the operator to employ both hands in working on the rims, etc. One of the qualities emphasized with the tool is its adaptability for forcing the rusted bead of a tire away from the inside of a rim and operating the tool from the outside of the wheel. The tool is very compact, constructed of high grade material and is inexpensive.

Perfection Non-Skid Climbers.

Perfection non-skid climbers are produced by the Perfection Non-Skid Climber Company, Edon, O. They are designed both for single and dual solid shoes and the company claims that the mechanical principle involved in the construction is such that they check instantly and automatically all sliding, skidding or slipping. The device comprises three working parts and it is held that they may be fitted or removed easily and quickly. The traction or cross shoe members are in the form of a corrugated plate and are secured by side links on either side. The links are retained by a chain construction and means are provided for fitting the same. They are made in widths varying from two to five inches and for wheel diameters of from 28 to 42. The duals are 3.5 and four inches respectively. An attaching tool is listed as extra.



Presenting Accessories Adaptable to the Commercial Vehicle, Including Dover Safety Fuel Can, Perfect Gasoline Filter, Vim Motor Starter, J-M Keystone Radiator Shield, Gilmer Endless Belt, Etc.

FOREIGN TRUCK NOTES OF INTEREST

INTERESTING GERMAN CHASSIS.

Five-Ton Daag Machine Presents Distinctive Features of Design and Construction.

While in some respects the Daag trucks, made by the Deutsche Last Automobil Fabrik Aktein-Gesellschaft of Ratingen, Dusseldorf, Germany, is not new in the country of its origin, the five-ton chassis presents distinctive features. It may be stated that the designer was at one time employed at the Saurer works in Switzerland, and some of the characteristics of that machine are reflected in the German vehicle.

Perhaps the chief feature of the motor, which is a four-cylinder, four-cycle unit, otherwise following what may be regarded as conventional practise, is the provision of an air braking device. This is an arrangement for temporary endwise displacement of the camshaft in such manner that air is drawn into the cylinders and compressed on each stroke. This is similar, at least, to the Saurer construction.

The control of the vehicle has been simplified materially. The one lever, which is pivoted at the centre of the steering wheel, controls, during the first part of its operation, the opening and closing of the throttle, which is embodied in the special Daag carburetor. When this throttle is closed, the same simple lever goes on to open a bypass to the atmosphere and to commence the displacement of the camshaft for air braking. A small subsidiary movement, interconnected with this lever mechanism, effects an alteration of the passage over the jet in the carburetor.

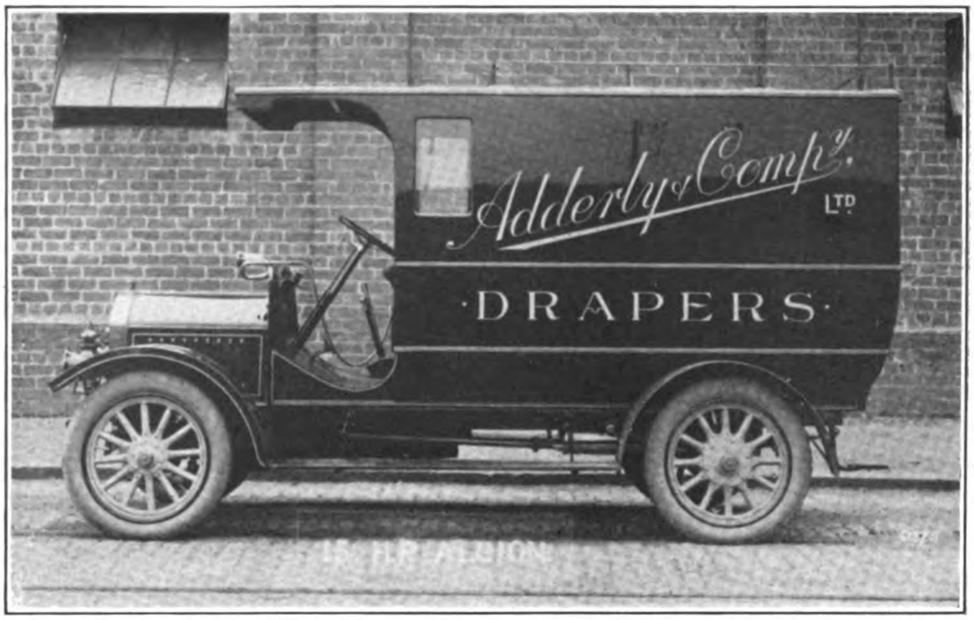
The carburetor is said to be adaptable to differing fuels. The ordinary float feed keeps the jet supplied with fuel in the usual way, but the jet is fitted with an internal tapered plunger, by which minute adjustment of the effective orifice is readily obtainable. This is separately controlled by a small lever carried on the dash. It is this special form of jet, in conjunction with the throttle arrangement, which is held to make possible the use of gasoline, benzol or alcohol.

The remainder of the chassis is of more or less conventional design, making use of a cone clutch, four-speed selective transmission, double chain final drive, countershaft and rear wheel brakes, etc. Because of the special type of carburetor, very economical fuel consumption is claimed, and this is further aided by the liberal use of high capacity ball bearings throughout the machine.

ALBION WORM DRIVEN.

Well Known Scotch Firm Adopts This Type for Light Delivery Wagon Work.

While the Albion Motor Car Company, Ltd., Scotstoun, Glasgow, Scotland, one of the oldest makers of commercial motor vehicles in the United Kingdom, always has made use of the chain drive, it has announced a new light delivery wagon equipped with worm driven rear axle. The company explains that it believes the chain drive cannot be excelled for heavy duty work, but adds that it has produced this latest model to meet the demand for a light, speedy, quiet vehicle.



Albion Worm Driven Light Delivery Chassis Equipped with Box Van Body.

The car is shown in an accompanying illustration. It has a four-cylinder, en bloc motor, rated at 15.8 horsepower under the Royal Automobile Club's formula, which is the same as that adopted by the Society of Automobile Engineers in this country. The bore is 3.125 inches and the stroke five, giving a bore to stroke ratio of 1:1.60. Cooling is by water, lubrication by gear driven pump and ignition by high-tension magneto with flexible drive.

The clutch is of the single disc type. The transmission gives three forward speeds and reverse, control being by a single lever on the gate system. Final drive is by an overhead worm and worm wheel run-

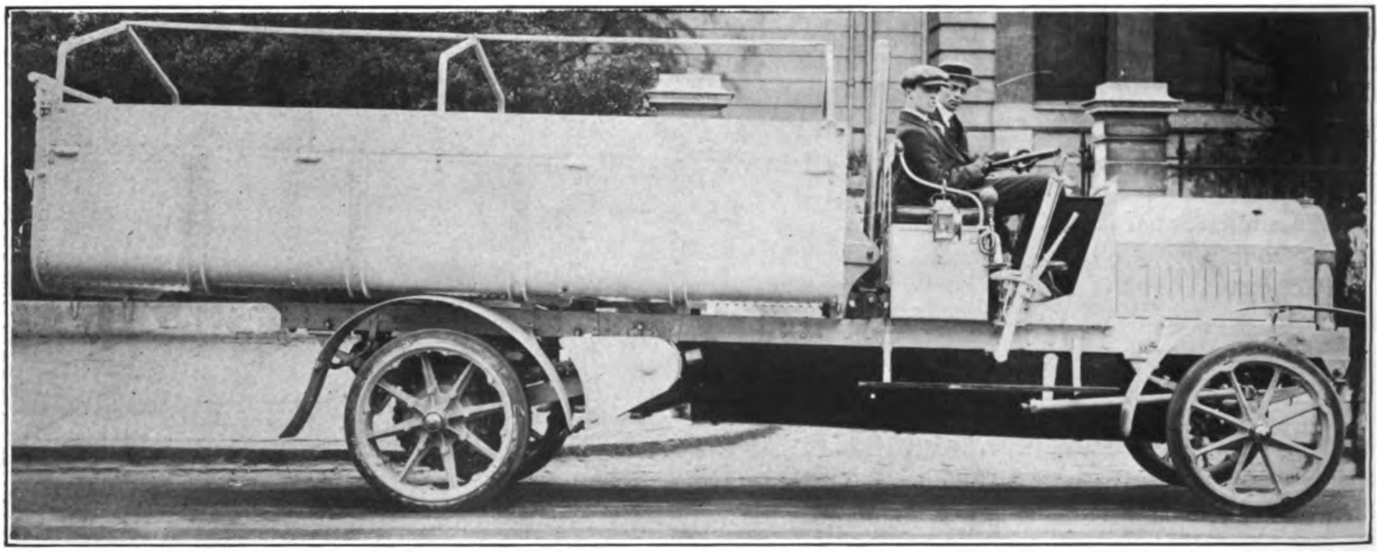
ning in oil and carried in special strong casings. Ball or roller bearings are used throughout and ball thrust washers take the thrust.

Wheels are of wood, artillery type, and pneumatic tires are fitted both front and rear, or solid members of ample section may be had on the rear upon option. The foot brake is external contracting, operating on a drum on the propeller shaft, while the hand member is internal expanding, acting on drums fixed to the rear wheel hubs. The frame is of pressed steel, with suitable pressed steel and tubular cross members.

LACRE STEEL TIPPING BODY.

An Interesting Installation Made by British Concern for South African City.

A new type of dumping body, constructed of steel and intended mainly for use in collecting and disposing of refuse, is that made by the Lacre Motor Car Company, Ltd., Letchworth, Hertshire, England, for the city officials of Johannesburg, South Africa, and shown herewith in two views. The municipality has found the wagon a decided success, both as to mechanical details and in a saving in time and labor.



Lacre Four-Ton Chassis Fitted with Steel Tipping Body for Collecting Refuse in Johannesburg, South Africa.

The chassis is a regulation Lacre four-ton, fitted with a 38 horsepower, four-cylinder, water-cooled motor. Ignition is by high-tension magneto. The clutch is a cone faced with leather and of large dimensions. The transmission gives four forward speeds and reverse, the three high speeds being operated by positive dog clutches. The reverse is obtained by manipulating a separate lever. Final drive is by means of roller side chains. Two sets of independent double-acting brakes are provided.

For use with this body the frame is shortened a trifle and stiffened at the rear to permit of tipping. The body dimensions are: Length, about 12 feet six inches; width, seven feet; depth, two feet nine inches. The rear portion is so arranged that when the vehicle is tipped it opens automatically, and it is held closed by a lever when in normal position. The screw hoist is of the telescopic type and permits of a body elevation of 45 degrees. Each of these vehicles replaces 12 Scotch carts and 20 mules.

INTERESTING SOUTH AMERICA.

Pope-Hartford Man on Trip Following Visit of Officials of That Section to Hartford Plant.

With a view to interesting South American cities in motorizing their various fire, police and municipal departments, as well as making a study of the commercial vehicle situation below the Canal zone, President George L. Dodd of the Pope-Hartford Company of Boston, recently sailed on a 28-day trip to that region.

Many South American officials have visited the Pope-Hartford Company and have displayed great interest in the ladder trucks, ambulances, chemical apparatus, etc. They stated their section possessed excellent possibilities for motor apparatus and Mr. Dodd's itinerary will cover 6832 miles and include: Havana, Cuba; Kingston, Jamaica; Colon, Panama; St. Pierre, St. Thomas and other South American points.

MORELAND IN HONDURAS.

California Product, the First to Enter That Country, Will Carry Government Mails.

H. E. Dean, who has had the contract for carrying the government mails in Honduras, Central America, has purchased a Moreland truck, made by the Moreland Motor Truck Company, Los Angeles, Cal. The capital of Honduras is a city situated in the heart of the country and is known by the strange name of Tegucigalpa. In order to receive mail from the outside world it has been necessary to haul it from Amapala, on the seacoast.

The Moreland truck is the first to invade Honduras and thus is the only motor driven vehicle in use in the country. From Amapala to Tegucigalpa runs the only good road in the entire country, the distance between the two cities being 115 miles. For 55 continuous miles this road is uninhabited and as the country lacks service stations, the truck must demonstrate the utmost dependability.

Mr. Dean plans to make the round trip in two days, thus giving the capital three deliveries of mail each week. With the native horse teams it formerly required a week to make the round trip, so that the service has been tripled by the introduction of this one truck. Passengers will also be carried and to guard against the frequent rain the machine has been given a cover of canvas.

WORM DRIVE IN CANADA.

First Machine Made in Dominion Utilizing This Construction Shown in Montreal.

The recent automobile show in Montreal, Canada, served to call attention to a new Canadian worm driven machine, made by the Northern Motor Car Company, Kingston, Ont. The Northern was shown in three models, of one, two and three tons capacity. Three others are produced, these being rated at 1.5, 2.5 and 3.5 tons.

The six machines differ materially from each other in that the one and 1.5-ton vehicles have unit power plants and four-speed transmissions, and the others have separate motor and transmission construction with three speeds forward and reverse. They follow standard construction in the main. The worm is of steel and the wheel of phosphor bronze. Motors are the long stroke, four-cylinder, four-cycle type.

GENERAL NEWS FROM ABROAD.

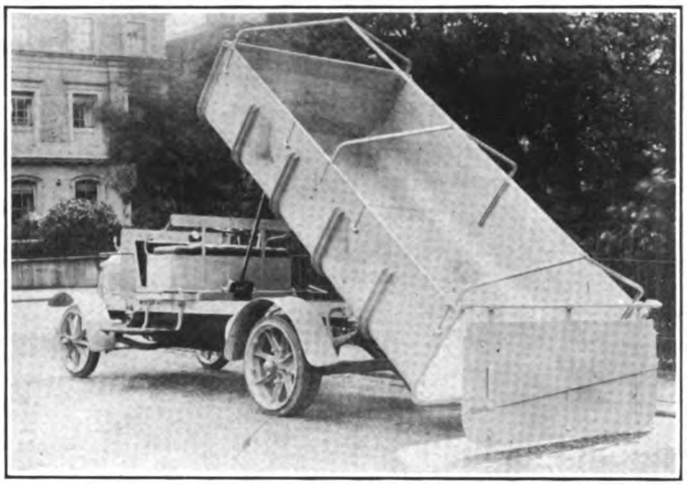
Trucks for Indian Mill Owners—It is stated that the owners of mills in various section of British India are studying the advantages of motor transports with a view to purchase. For some time these men have been aware of the disadvantages of their present means of haulage, but the belief that European drivers and attendants would have to be secured in order to obtain successful operation has prevented decision in favor of motors in the past.

Motors in South Africa—The British trade commissioner for South Africa has reported to his government that the market in that territory appears to offer great possibilities for commercial motor vehicles, and advises that British firms form an organization for its exploitation.

Transport Facilities at Liverpool Docks—In view of the recent discussion concerning the congestion of traffic at the docks in Liverpool, England, and its possible solution by the use of motor transports, the Liverpool chamber of commerce has decided to form a committee, consisting of members of its body, the corporation of the city and the shipping and other trade interests, to look into the matter.

Motor Omnibuses in China—A Chinese firm has requested information from British manufacturers concerning three or four 36-passenger motor 'buses, complete with bodies and tires. Inasmuch as this is held to be the first installation of such equipment in that country, it is believed that the future of the market will depend largely upon the placing of these vehicles.

Business Vehicles in Brazil—According to the local press the use of motor transports is increasing rapidly in Brazil. There are 442 automobiles for hire and 39 motor trucks in Santos, and 264 of the former and 80 of the latter in Sao Paulo. Motor services are running on the following routes: Aperecida to Guaratingueta, Capivari to Monte-Mor, Itu to Salto, Monte-Mor to Elias, Fausto to Reboucas, Paraibuna to Sao Jose dos Campos, Riberao Preto to Sartaosinho, Limeira to



Lacre Tipping Body in Dumping Position.

Piracicaba, Taubate to Tremembe and Porto de Rei to Itanhaen.

Agricultural Trials in Italy—The Ministry of Agriculture, Industry and Commerce in Italy, will superintend a trial of agricultural motors at Parma during the coming summer. The exact dates have not been made public, but all entries must be filed with the secretary of the Italian Touring Club, Via Monte Napoleone 14, Milan, Italy, before May 31. The competition will be divided into three classses, one for deep plowing, one for motors suitable for agricultural purpose and one for machines using kerosene or gasoline as fuel.

The Atlantic Ice & Coal Corporation of Atlanta, Ga., has just placed an order for 15 White trucks to be put into immediate service by the company. R. W. Woodruff, purchasing agent of the company, closed the contract with R. H. Johnson, New York City manager of the White Company's branch. The vehicles ordered are of the three-ton and 1.5-ton types.

HINTS FOR PROPER MAINTENANCE

A Department for the Owner, Driver and Repairman.

FUEL AND COLD WEATHER.

One cannot be too careful about the fuel in cold weather. This applies both to the operator and the garage attendant. The careful driver will make sure that all gasoline is strained before being poured into the tank, even going so far as to personally supervise the operation. While this would appear a needless precaution, an instance took place recently where the garage attendant neglected to use the chamois in the funnel, creating considerable trouble for the driver of the truck.

Having occasion to make a stop and one requiring some 30 minutes, the operator stopped his motor and blanketed it as it was a very cold day. When he returned and attempted to restart the engine there was trouble. Repeated cranking and even priming of the cylinders failed to obtain the desired results. After exhausting his knowledge of starting methods the driver telephoned to the garage for assistance.

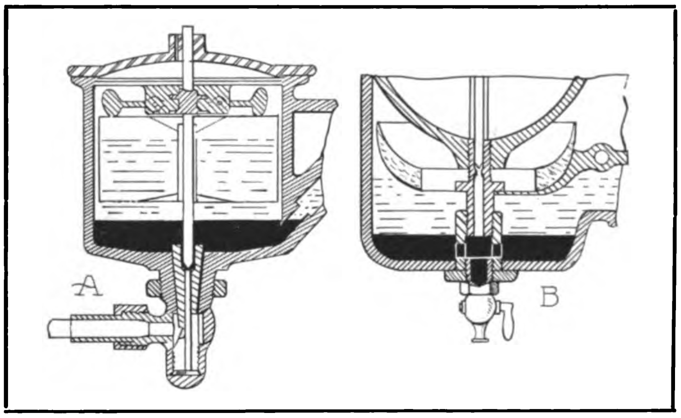


Fig. 1—Illustrating the Importance of Keeping Fuel Free from Water in Cold Weather: A, Showing Formation of Ice in Float Chamber, Stopping Passage to Spraying Nozzle; B, Depicting Level of Congealed Mass Above Apertures to Nozzle.

When the expert arrived he began a systematic search and located the trouble in the carburetor. Upon removing the member it was found that ice had formed to such an extent that the line leading to the spraying nozzle was choked. After thawing out the mass and cleaning the vaporizer the engine was started without difficulty.

All fuel should be strained carefully, more so in cold weather than in the summer. Not only should this precaution be observed, but the filter should be opened occasionally and all water and foreign elements drained from this member, as it is possible that the water will freeze and create trouble.

A simple test for frozen water in the carburetor is to open the petcock under the vaporizer and note if the fuel flows freely. If not, and the opening is free from obstruction, which may be tested by using a piece of wire, it may be taken for granted that ice has gathered. The only remedy is to remove the vaporizer and clean it.

At Fig. 1 A is presented an example of the possibility of ice forming in the carburetor, the congealed mass being denoted by the dark lines. It will be seen that the ice completely blocks the entrance of the fuel and that under this condition it would be impossible for the gasoline to reach the spraying nozzle and be converted into vapor.

At B is shown another design of carburetor. Here the fuel flows into the spraying nozzle through two small apertures. It would require only sufficient frozen water to cover these openings before the supply of fuel would be shut off. It should be remembered that water begins to congeal at 32 degrees Fahrenheit and that when the thermometer records well below this mark it requires but a short time for a small quantity to become a solid mass.

S WRENCHES AND THEIR USE.

With a complete set of S wrenches having various openings the work of overhauling the chassis or making adjustments is simplified, provided the workman has a knowledge of their proper application. A common fault with the novice is to employ a wrench that is too large; that is, the nut or bolt is smaller than the opening of the jaws of the tool. This results in damage to the nut by rounding off its corners.

In using the S wrench, or any other for that matter, the jaws should be fitted snugly so that there is no play. Sometimes it is necessary to give the free end of the wrench a sharp blow with a hammer to start a refractory nut and when this method is employed care should be taken to fit the tool so that the impact of the hammer will tend to drive the wrench on the nut, not off. If placed incorrectly the blow will cause slipping if not damage.

At Fig. 2 are shown several suggestions for tight-

ening or loosening nuts or bolts not easily accessible. Sketches A to F illustrate methods of securing greater leverage when tightening a nut and when it is impossible to accomplish the work with a single tool.

Frequently the nut is so located that a wrench cannot be utilized because of lack of space. At G, H and J are shown methods of doing the work, and it will require but little practise to master the operations. A rigid piece of metal should be employed, an iron or brass bar for example, and never the cold chisel, which will ruin the nut. The blows of the hammer should be sharp and clean, and the force applied for a brief part of a second is sufficient to start the nut or bolt.

The box wrench is of service when some foreign substance has become lodged between the threads of the nut and bolt, and when tapping with a hammer is necessary to loosen the parts. The wrench is fitted over the nut and receives the impact of the hammer, thus saving the nut from damage.

The work of removing a small nut or a union from light copper or brass tubing, the oiling or acetylene systems for example, requires considerable care on the part of the workman. With annealed copper or brass pipe it is an easy matter to twist the tubing, especially if the nut or union be set up snugly.

The best method is to fit a wrench and give the handle a light, quick tap with a light hammer. This will usually start the nut, etc., without danger of twisting the tubing. The same method should be utilized when removing a hub cap from a wheel. Some of these members are thin and if considerable leverage is exerted through a long handled wrench, the metal may become bent out of shape. On the other hand a more solid cap will resist the leverage and if a piece of pipe is slipped over the handle of the wrench to secure greater leverage, the spindle may become strained. There is a limit to stresses to which the S wrench may be subjected and these tools should be used properly and not unduly strained.

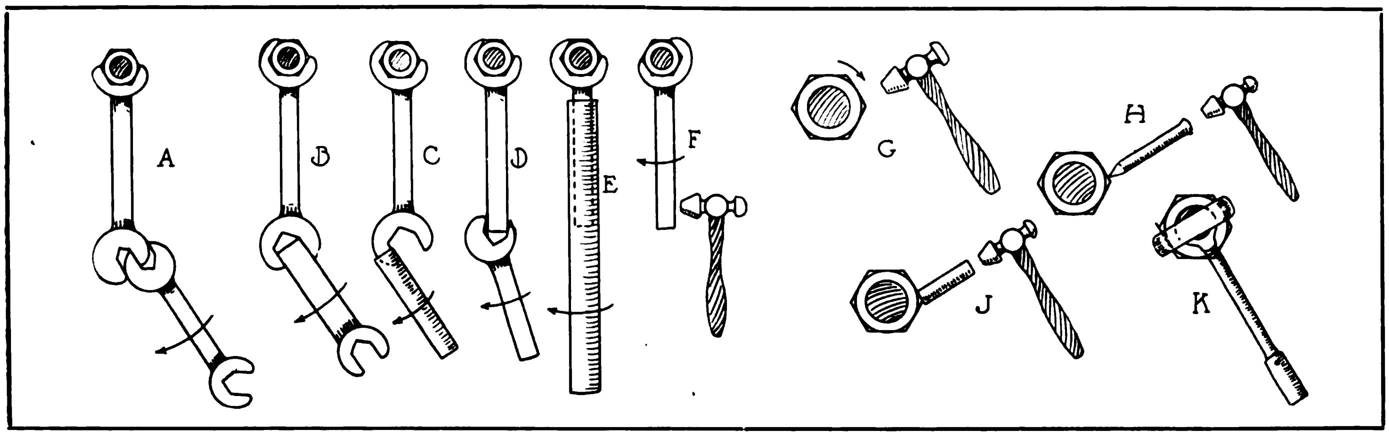

Fig. 2—Depicting the Proper Use of S Wrenches: A to F, Showing Methods of Obtaining Greater Leverage; G to K, Suggestions for Starting Frozen Nuts.

A STARTING SUGGESTION.

When flooding the carburetor and priming the cylinders with gasoline fails to start a motor on a very cold morning, heat should be applied to the carburetor and intake manifold. If convenient, heat some water very hot and after covering up the air intakes of the vaporizer, pour the heated fluid over it and the intake pipe. Then flood the carburetor and prime the cylinders and the engine will start, provided the ignition and other components are in proper working order. Heating the carburetor assists in the vaporization of the fuel, while warming the intake manifold prevents the vapor from condensing as it strikes the otherwise cold walls of the piping. The mixture should be enriched slightly for starting and after the motor has become warm the needle valve replaced in its original setting.

INSPECT WHEEL BEARINGS.

Wheels of the ball bearing type should be examined for looseness occasionally as there is danger of the balls breaking and the bearing becoming ruined. It is an excellent plan to jack up the wheels and test them for play. When ball bearings are employed the adjusting cone should be tightened until the wheel is absolutely stiff, then the cone should be slacked off about one-quarter of a turn and locked. The wheel should then be rotated, trying it in different positions to note if the bearing binds as it may be possible that the spindle is sprung. If the latter condition exists, it will be impossible to set up the bearing snugly without the balls binding on one side. Always clean out the old lubricant and replace with new, and be sure to replace cotter pin securing locking nut. In filling the hub cap care should be exercised not to use too much grease as it may prevent the cap from being screwed up tightly.

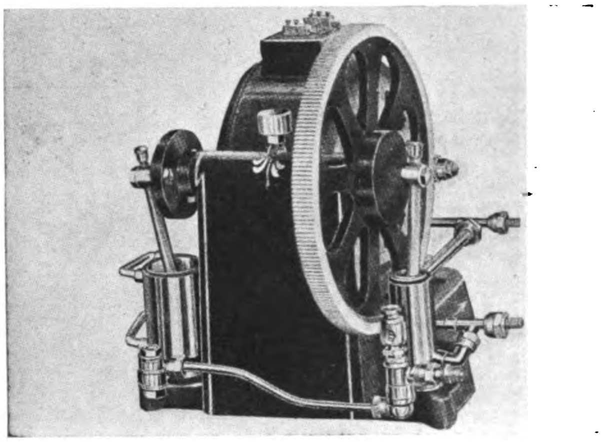
WHEN SPARK PLUG IS FROZEN.

Sometimes difficulty is experienced in removing a spark plug from the cylinder and frequently the porcelain is broken by a too vigorous application of the wrench, or if heat is utilized the insulator may be cracked. It is an easy matter to loosen the retaining nut of the electrode and remove the part, after which the shell may be handled in safety.

GARAGE AND SERVICE STATION EQUIPMENT.

CHAMPION ELECTRIC AIR PUMP.

An air compressor maintaining a constant supply in the tank, is a valuable addition to the garage equip-



Champion Automatic Compound Electric Air Pump Designed Especially for Garage Service.

ment as by it tires may be inflated, the chassis cleaned and numerous other forms of work completed with a saving of time and labor.

The Cleveland Faucet Company, Cleveland, O., manufactures an outfit especially designed for this work and in an accompanying illustration is presented the No. 6 Champion automatic compound electric air pump and automatic switch. It is held by the maker that the capacity of the tank is sufficient for the largest garage and that an 18-gallon container will furnish air enough to inflate a large tire every minute and at any pressure. A constant pressure of 100 pounds or less is maintained automatically and the pump operates only when the supply of air is reduced to a predetermined amount.

The compound pumps are back geared direct to the electric motor, and are constructed entirely of bronze with valves and connections of the same material. The pistons are water jacketed, maintaining a constant circulation of cool fluid, and a water tank eliminates the necessity of the continuous city supply. This tank is substantially constructed and is located approximately 1.5 inches above the return connection.

The automatic switch controlling the pump is simple in construction and the company emphasizes its durability, also the fact that it requires no other attention after installation than an occasional oiling. It is stated that the pump will automatically fill an 18-gallon air tank at the following pressures: Twenty-five pounds in three minutes, 50 pounds in eight minutes, 75 pounds in 12 minutes and 100 pounds in 16.5 minutes.

The specifications are as follows: Dimensions of pump, 15 inches wide, 19 inches deep and 18 inches high; switchboard, nine by 14 inches; diameter of large cylinders, 2.25 inches; small, 1.25 inches; stroke of piston, three inches; motor, alternating current, one-third horsepower; direct, .25 horsepower; revolutions, 150 a minute. Catalogue and price lists will be mailed upon request.

TAPS AND DIES.

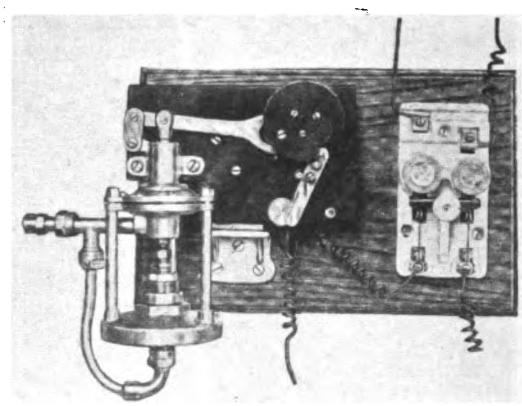
Taps and dies are broken in use and must be replaced from time to time. The American Tap & Die Company, Greenfield, Mass., is issuing a neat illustrated catalogue showing various forms and sizes of dies, reamers, screw plates, taps, tap wrenches, etc., which will be mailed to the trade free of charge upon application.

FOSTNACHT VALVE RESEATER.

The National Auto Specialty Company, Tama, Ind., is marketing the Fostnacht valve reseater, a tool designed especially for reseating and polishing valves with a minimum outlay of energy. The outfit comprises a large cutter, designed to fit all sizes of 45-degree valves and five sizes of cutters are constructed from 1.5 to 2.25 inches. The latter are made of a high grade carbon steel and they may be removed and resharpened.

VALVE GRINDING COMPOUND.

An efficient grinding paste, and one that costs but a few cents to make, is prepared by mixing No. 120 carborundum with oil. Badly pitted valves will yield to a treatment of this compound. It can be mixed as needed and should be employed sparingly as it cuts quickly. The best way is to place the carborundum in the cover of an old tin box with the oil separate. The powder is



Illustrating Automatic Switch Utilized with Champion Air Pump Outfit.

then worked into the lubricant in suitable quantities. Care must be taken not to use too much of the carborundum. After using this material the valves and their seats should be washed thoroughly with gasoline.

CORRESPONDENCE WITH THE READER.

Anti-Freezing Solution.

(27)—Am having considerable trouble with anti-freezing solutions heating up motor. The machine was an old pleasure car and the radiator has been soldered a number of times to stop leaks. I used denatured alcohol, but the solution boils very easily and the engine gets very hot. As the machine is stored in an unheated building I do not dare to try drawing off the water as a garage man told me that it would be impossible to drain off all the fluid. Isn't there some other kind of solution to employ that will not heat as easily as the alcohol?

A SUBSCRIBER.

Portland, Me., Feb. 18.

An alcohol solution boils at a lower temperature than water, depending upon the percentage of alcohol. A calcium chloride solution would be better, but is more troublesome to prepare. The fact that the cooler has been repaired several times would indicate that it is not performing its function properly and it should be thoroughly cleaned with a saturated solution of common washing soda. Dissolve as much as possible in water and fill the radiator. Run the motor for 10 or 15 minutes, after which drain off the fluid and replace with fresh water. Allow this to circulate, then remove and refill the cooler with the anti-freezing solution.

It would be an excellent plan to examine the water pipes and pump to ascertain if they be free from obstructions. Sometimes an old rubber pipe will deteriorate to such an extent that the inner layers will loosen, impeding the flow of fluid, although the exterior of the tube appears in good condition. The pump may be worn so that it does not deliver the proper amount of water to the cylinders. A rich mixture will cause heating and improper valve and ignition timing are also factors to be considered.

There are several anti-freezing solutions which are held not to evaporate or heat as easily as water, among which may be mentioned Lubro, which was described in a recent issue under the head of New Accessories.

Forms of Piston Rings.

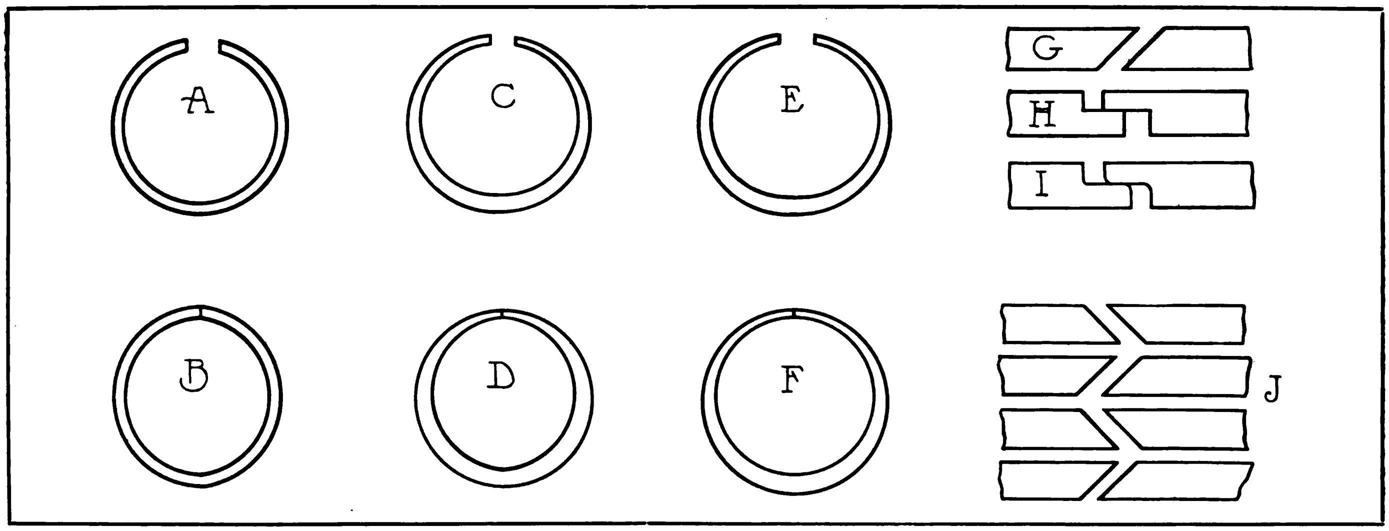
(28)—In reading descriptions of trucks and motors in your book I notice that piston rings are cut eccentric and concentric and that emphasis is laid upon the method of cutting and finishing. What is the difference between the two types and what is the advantage of either?

J. B. B.

Columbus, O., Feb. 14.

It is a generally accepted idea that if a ring be turned concentric inside and out and then split, the outward pressure on the cylinder walls, when the ring is closed and in its place, will not radiate from the centre. This is demonstrated in the accompanying illustration at A and B, showing the ring open and closed, respectively. It will be noted that with this design there are three bearing points, one either side of the split and at the lowest extremity of the circle.

Such a type would not be practical for service in a cylinder, so the ring is made thicker in the first instance and then turned to a true circle after being closed at the gap, thus giving a full bearing surface all around its circumference. Before doing this, however, some manufacturers make it a practise to turn out the inner periphery of the ring eccentric to the outer, in order to equalize the pressures at all points of the ring. This is depicted at C and D.



Illustrating Piston Ring Construction: A, Concentric Type, Open; B, Closed; C, Eccentric, Open; D, Same Closed; E and F, Eccentric Finished to True Circles Inside and Out; G, H and I, Showing Different Steps; J, Diagonally Cut Rings Arranged Oppositely.

A ring of the eccentric type is shown at E and F and costs but slightly more to manufacture than the type previously mentioned. It is turned to a perfectly true circle inside and out with the gap closed, the outer circle being eccentric to the inner. By referring to F it will be noted that not only are the pressures even on all parts of the ring, but less pressure is required to make it gas tight. It is held that there is less uneven wear of the cylinder walls, less heat developed and greater efficiency of the motor.

Relative to joining the rings, there are several methods, some of which are illustrated at G, H and I. That at G consists of a diagonal cut across the face. There is a tendency in this type to rotate in the opposite direction to that in which the lower diagonals point, and some make it a practise to cut every other ring in the opposite direction to its neighbor as shown at J.

RECENT MOTOR VEHICLE PATENTS

Walter Tire.

Benjamin Walter, Livermore, Penn., has been granted a patent for a resilient tire. It comprises the usual outer casing and has a plurality of inflated members completely filling the interior of the outer member. These members have flat abutting faces and are provided at corresponding points with the co-operating elements of a ball and socket joint.

Hart Resilient Tire.

Among the patents granted recently is that to Harry D. Hart, San Diego, Cal., for a resilient tire for vehicles. The material employed is a woven wire cable, this being coiled transversely of the rim of the wheel. A core having inner and outer grooves is fitted for receiving the loops of the coil, and grooved rims are provided, these fitting on the inner surfaces of the core and being adapted to secure the parts to the felloe of the wheel.

La Driere Wheel.

A patent has been granted to Joseph L. La Driere, Albuquerque, N. M., for a vehicle wheel. The hub is a combination member having an annular groove in its inner side and an outer section having a central recess in its outer side. The hub also has a circumferential groove with transverse ribs in its bottom, and a large number of teeth are provided on the sides of this groove. Transverse bolts are utilized for connecting the sections and their heads are disposed in the annular groove. The locking nuts are mounted on the outer ends of the bolts and are disposed in the central recess. An inflated tube surrounds the hub and is seated in the circumferential groove. This has an inflation tube in the outer end which is disposed in the central recess. An outer casing portion surrounds the hub and the inflated tube in such manner as to permit of vertical movement of the hub within said casing portion. Transverse ribs are arranged in radial alignment with the spaces between the teeth of the hub and have inwardly extending end portions on the ribs. The device includes an annular packing bearing against the inner side of the hub, and a closure plate detachably connected with the outer side of the casing portion.

Bordo Priming Device.

A patent for a gas engine attachment has been granted to Lambert J. Bordo, Hillside, Penn., which includes means for priming the cylinder of an engine. It comprises a valve casing which is screwed into the valve plug member or cylinder wall and is provided with a passage extending through it. A valve is incorporated and is so constructed that it may be moved by a handle and lever so as to provide communication between the cylinder and the outer air. Another movement of the lever closes the passage, but allows fuel or other fluid to be introduced into the cylinder through means of a cup attachment. A transparent diaphragm is employed to close the branch passage and by it the interior of the cylinder may be inspected. The device presents interesting features in that it may be employed to ascertain the color of the exhaust as well as to serve for a priming member.

Dion Safety Crank.

Among the devices patented recently for preventing injury to the operator when cranking the internal combustion engine is the safety crank invented by Francois Dion, Manchester, N. H. The engine shaft has an extension and integral clutch teeth which engage with similar teeth of a longitudinally movable starting crankshaft having a detachable extension which telescopes over the engine shaft extension. Means are provided to prevent the detachable member from being removed. A ratchet member is loosely mounted on the detachable portion and means are included to prevent backward rotation. The ratchet member has inclined teeth, these extending laterally, and co-operating teeth are fitted to the starting crankshaft with which those on the ratchet member engage when the clutch members are in engagement.

Erickson Spark Plug.

Frederick William Erickson, New York City, has patented a spark plug the shell of which is cylindrical in form and has a perforated lower end with inwardly bent sparking points. A supporting ledge is provided in the upper part of the shell and a perforated mica disc rests upon the ledge. The insulating post is also perforated and its lower end extends into the upper part of the shell. A collar is adapted to bear on the exterior of the post and upon the edge of the disc, securing the latter to the shell. A metal rod extends through the interior of the shell and the post, one end of which is separated from the sparking points by a gap, while the opposite end is provided with a screw thread and a nut.

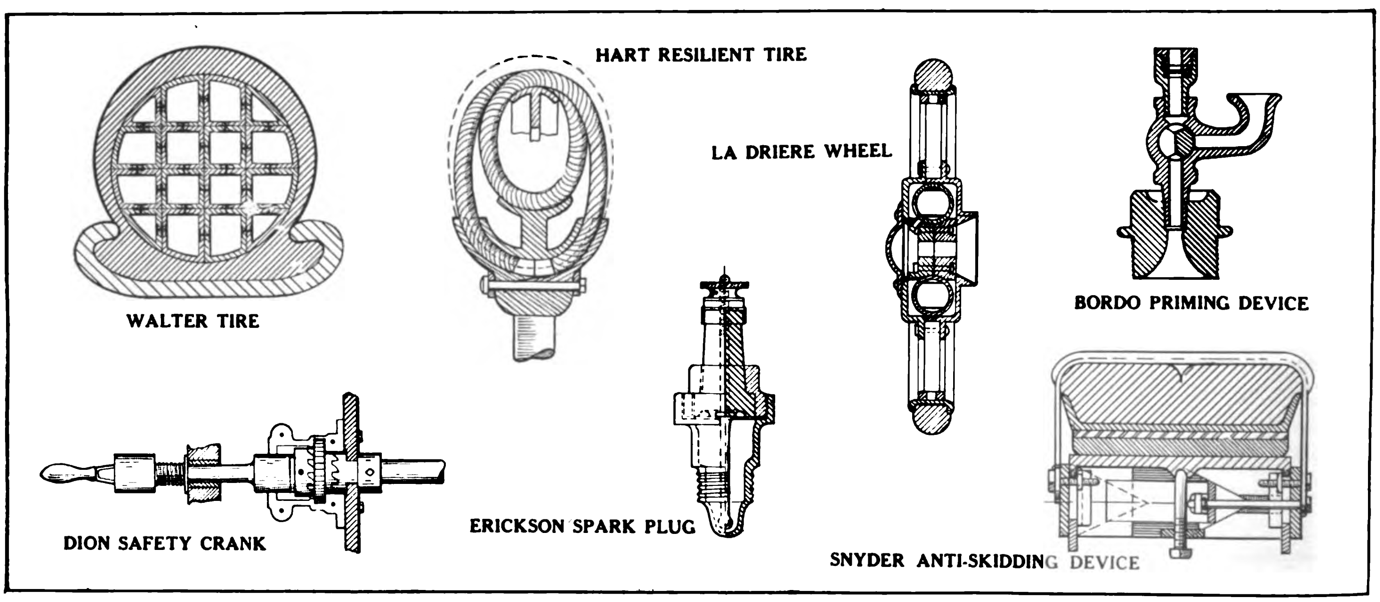
Snyder Anti-Skidding Device.

William H. Snyder, Ashbourne, Penn., has been granted a patent for an anti-skidding device applicable to solid tires. It comprises a band adapted to engage the tire, and a frame to which the band is connected. There is a second frame moveable with respect to the first, and both have cam faces thereon. Means also are provided for actuating an expander having cam faces adapted to engage those of the two frames. A resilient connection is incorporated between the expander and the actuating members.

Other Patents Gone to Issue.

Tire Mail, Joseph B. Duhring, Chestnut Hill, Penn. A tire mail comprising crossed strands of chain links, the links of one strand inclosing a single loop in the adjacent link of said strand and the superimposed link of a crossing strand.

Oil Can, Ralph A. Wakefield, Sacramento, Cal. The can is similar to those of conventional construction, but carries a spring actuated pin projecting from the bottom to the top of snout. By compressing the bottom of the oiler the pin is forced away from snout opening, allowing the lubricant to flow. Normally the spring retains the head member upon its seat, closing the aperture.

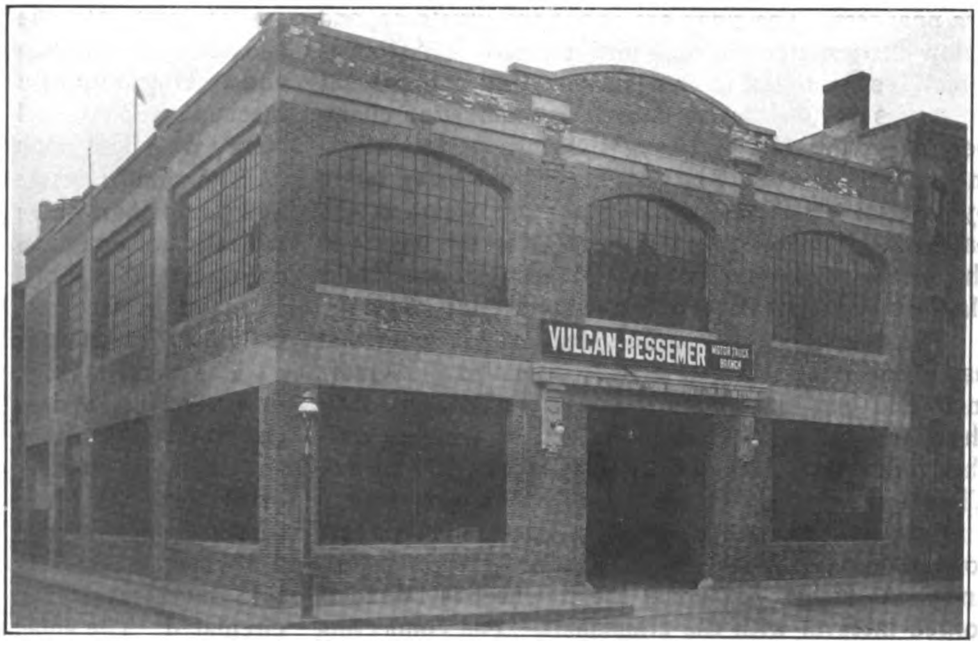


Illustrating Some of the More Recent Patents Applicable to the Commercial Vehicle.

THREE BESSEMER TRUCK MODELS FOR 1913.

THE Bessemer Motor Truck Company, Grove City, Penn., which placed in the market a 2000-pound wagon as its first product, now produces three sizes of machines, these being of 1500, 2000 and 3000 pounds capacity. The policy of the company as first established was to build a single type of vehicle, but after carefully prospecting the market and ascertaining the requirements for what may be regarded as the light and quick delivery service, it was decided that it would be best to have types that might be utilized for specific purposes rather than to expect that the single size would serve those whose needs were general. The two later machines are built to practically the same design and there is a similarity throughout, but the smallest chassis differs from the others.

The Bessemer delivery wagons have been designed with a view of securing all the qualities that make for reliability and endurance, and insure a minimum of labor and expense in care and maintenance, for it is necessary for the owner of a motor delivery vehicle to have its service constantly, and withdrawal for any cause means the loss of its use for the time being and the added cost of a substitute. In the design of the machines great care was given to accessibility and simplicity, that every moving part could be examined and lubricated and adjusted whenever necessary, and that whatever repair might be needed could be made without removal of more than a single assembly.



The Service Station of the Bessemer-Vulcan Motor Truck Branch at 58-62 Church Street, Boston, Maintained for the Benefit of New England Users of Bessemer and Vulcan Machines.

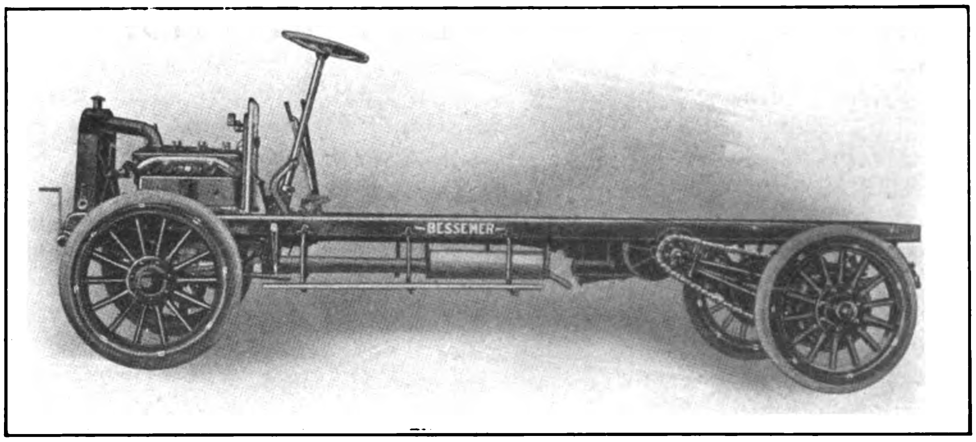
The hooded motor was decided on because it was believed that this type is the easiest to examine and work upon, all parts being exposed by lifting the hood, and a great deal of the attention needed can be given without removal of any of the auxiliaries. The chassis length is such that there is abundant loading space behind the seat for the driver, and the proportions were decided with the purpose of equalizing the tire load and minimizing the tire expense. The construction of all three designs has been with an ample margin of safety and every component has been determined to endure a stress much in excess of the normal requirements, and the choice of special materials has been made to afford such strength with a minimum weight of metal.

For the purpose of description the 3000-pound chassis will be considered, and this will give the general characteristics of design and construction. The 2000-pound machine differs but little aside from proportions of the components. The 1500-pound chassis has a smaller motor and there are some changes in the design.

The motor is a four-cylinder, water-cooled, vertical, L-head type, with bore of 3.75 inches and stroke of 5.25 inches, with the cylinder cast en bloc. While the S. A. E. rating is 22.5 horsepower, it is claimed for this engine that it will develop approximately 42 horsepower at 1500 revolutions. The cylinder block is cast from a special grade of reverberatory air furnace iron, with extremely wide and heavy base flanges and with a large water jacket head. The water spaces are large and the casting is so made that the passages are thoroughly cleared and there is a positive circulation of the water. After the rough boring the blocks are aged to eliminate distortion from casting strains, and are then reamed and ground to size. Before and after machining the blocks are subjected to water pressure tests to develop leaks and possible defects and by a special process the water jackets are cleared. The water jacket head extends the entire length of the block and the head or cover plate is retained by a series of cap screws.

The crankcase is an aluminum alloy casting that is in two sections, the upper half carrying the three main bearings. The lower section is divided horizontally by a web, above which is the oil basin carrying the pits in which the lubricant is collected for the splash lubrication, and under which is the oil reservoir. This half of the case may be removed without loosening the main bearings of the engine. The arms of the motor are cast integral with the upper section.

The extra length pistons are cast of the same metal as the cylinder block and after turning are ground to size. Each piston is channelled for four rings that are



Side View of a Bessemer 3000 Pounds Capacity Delivery Wagon Chassis, a Construction Noticeable for the Long Loading Space with Reference to Wheelbase.

of the split eccentric type, ground on the edges and the faces to accurate fit. The rings are specially machined to relieve all casting strains and when fitted the motors are run under separate power to insure the rings having perfect bearing in the cylinders before the final test. The rings are above the wristpins, and below the wristpins in each piston are five oil grooves which insure an equal distribution of oil and prevent an excess of lubricant reaching the combustion chamber. Extreme care is taken to secure perfect alignment of the wristpin bearings, the pistons being bored by special machines. All pistons are weighed and balanced. The wristpin bearings are in the bosses in the piston walls and the wristpins are of steel tube clamped in the small ends of the connecting rods.

The crankshaft is a carbon steel drop forging that has a tensile strength of 90,000 pounds to the square inch, and has three main bearings, these being 2.75, three and four inches respectively from front to rear, this giving a total main bearing length of 9.75 inches. The diameter is 1.75 inches. The shaft is heat treated and carefully ground to size. Special flanges are formed to prevent end thrust to afford greater endurance. A flange to which the flywheel is bolted is forged integral with the crankshaft. The connecting rods are drop forged I sections of carbon steel, and the wristpin and crankpin ends are bored and reamed on special machines to secure positive alignment. The crankpin bearings are clamped in the ends of the rods by special nickel steel bolts that are secured by a locking device.

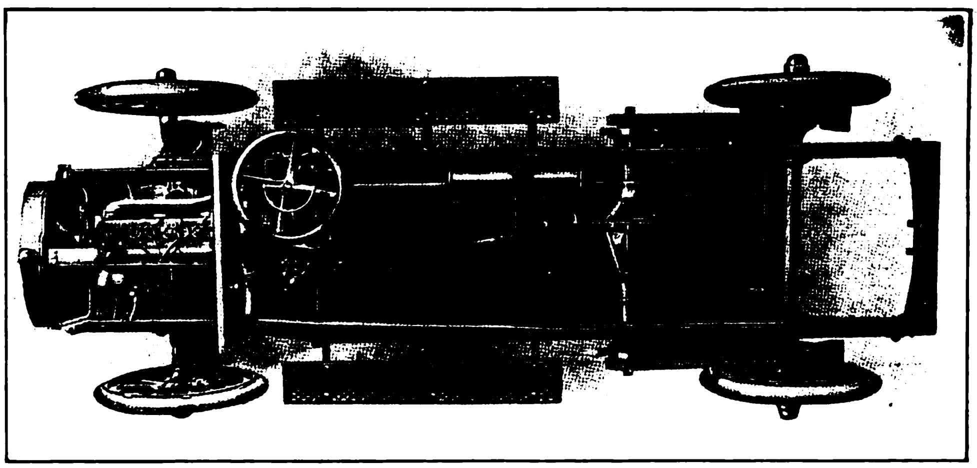
There is a single camshaft that is drop forged from low carbon steel with the cams integral, and after the shaft has been turned and the cams roughly machined it is heat treated, and then the cams are finish ground. This insures extremely accurate cams.

All the crankshaft, camshaft and connecting rod bearings are of nickel babbitt of high grade and the connecting rod and crankshaft bearings are held by brass retaining screws. All bearings are carefully fitted, expanded by special arbors, reamed and scraped to fit. The connecting rod bearing adjustment is obtained by steel shims. The camshaft is so fitted that it may be removed by taking off the gearcase cover.

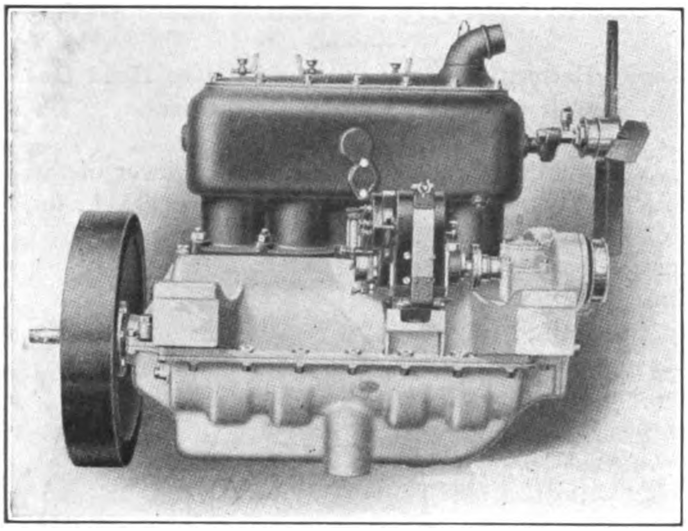
The valve ports are two inches diameter and the valves have nickel steel heads and carbon steel stems, electrically welded. The stems move in cast iron guides, removable when worn. The valve clearance is sufficient to insure complete scavenging of the cylinders and full charges of fuel gas. The valve stem ends are hardened to resist wear. The tappet rods are a mushroom type that operate in cast iron guides inset into the base flange. These rods are hardened and at the upper ends are adjusting screws and locking nuts to compensate for wear. The valve mechanism is covered with plates fitting into end and centre webs and retained by wing nuts.

The timing gearset includes one crank, cam, idler and pump shaft gears, which have wide faces and are helically cut on automatic hobbing machines to obtain accuracy. The gears are shaped with particular care to maintain accurate centres. The gears are practically noiseless in operation.

The motor is lubricated by a pair of plunger pumps driven by eccentrics from the camshaft which force the oil through tubing to the rear main bearing and to the timing gearcase. The excess oil drains to the base of the case and into the pits into which the big ends of the connecting rods sweep. The oil is maintained at a constant level in these pits and the overflow runs into the reservoir, where it is filtered before it is again circulated. The splash lubricates the centre main and the connecting rod bearings, the cams, tappets and guides, wristpins, pistons and cylinders, and the camshaft bearings are lubricated by a flow from pockets



Top View of a Bessemer Delivery Wagon Chassis of 3000 Pounds Capacity, Showing the Compact Power Plant and the Unit Assembly of the Gearset Case and Jackshaft Housing.



The Magneto Side of the Continental Motor Used for the 3000 and 2000-Pound Bessemer Chassis.

which are cast in the wall of the crankcase.

The motor is cooled by a thermo-syphon circulation of water through the cylinders, there being large inlet and outlet manifolds and a channel in the cover plate of the cylinder head affords a direct movement of the liquid from the rear across the heads of the forward cylinders. The radiator is large and this is cooled by a fan mounted on the forward end of the block on a bracket that is adjustable to give the necessary tension to the flat belt. This belt is driven from a pulley carried on a forward extension of the magneto drive shaft. The exhaust and intake manifolds are bolted to the cylinder block well above the valves, so that these may be worked on without removing the manifolds.

The carburetor is an automatic float feed type and the ignition is by a high-tension Eisemann magneto.

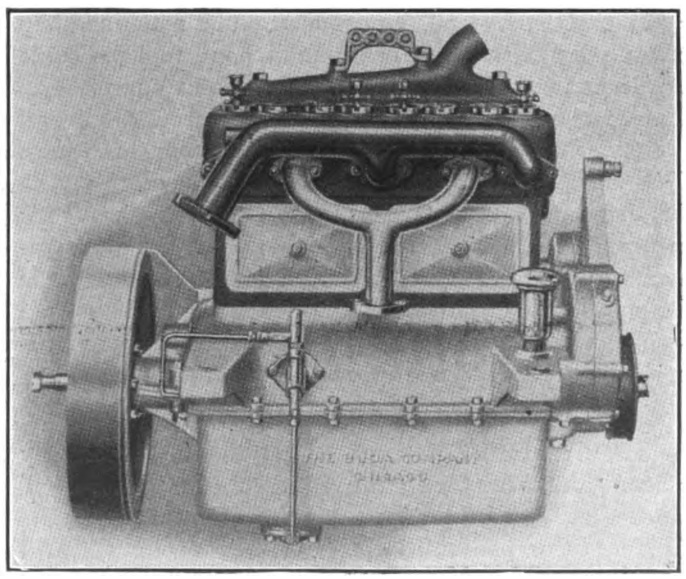
There are two centre cross frame members. The forward member carries the bracket in which is mounted the driving shaft and on this member is also the quadrant in which the gearset and the emergency brake levers are mounted. Forward of the bracket is the clutch shaft, on which is the cone clutch, faced with an anti-friction material. The cone is a spider with wide arms, and the construction, though light, is very enduring. The spring tension can be adjusted from the outside and the entire clutch can be removed by loosening three bolts. On the frame cross member are the clutch pedal and emergency brake shafts and the foot brake lever. The control lever quadrant is in the centre and this may be taken out by removing four bolts.

The second cross frame member carries a bracket that supports the forward end of the transmission gearset. The gearset case is cast integral with the jackshaft housing. Between the two cross members is the driving shaft, with a universal joint at either end. The gearset is a sliding gear selective type, giving three forward speed ratios and reverse, and the shafts and gears are of nickel steel, heat treated. The gears have very wide faces and the shafts are mounted on imported annular ball bearings. The jackshaft housing is cast steel and the construction is full floating type with imported annular ball bearings. The differential is a bevel gear design.

The frame is a heavy pressed steel channel section and it has four cross members. This is carried on semi-elliptic springs forward and a semi-elliptic platform spring at the rear, the platform having a cross member mounted in a block of unusual size. The shackles are very heavy and should endure a great length of time. The forward axle is an I section of Timken design, with ample steering knuckles, with the pivots and spindles fitted with Timken roller bearings. The rear axle is a rectangular steel drop forging with big spindles and Timken roller bearings. The radius rods are fitted so as to have a vertical movement with relation to the rear axle, and a transverse movement at the connection at the jackshaft hanger. The radius rods are adjustable with eccentrics and vernier adjustments that are bolted at any desired relation. The wheels are 34 inches diameter and are shod with 3.5-inch tires forward and four-inch tires rear. The control is by the usual levers and pedals. The service brake is internal expanding in a drum 14.75 inches diameter, having a three-inch face, and the emergency brake is external contracting on the same drums. The brake bands are faced with Raybestos and cannot be affected by any condition that might result from service.

The 2000-pound chassis is slightly smaller in its general proportions than the 3000-pound machine, but the principal difference is in the length of the frame and the size of the axles and wheels, the wheel spokes being lighter and the tires being three-inch forward and 3.5-inch rear. The wheelbase of the 3000-pound chassis is 130 inches and of the 2000-pound chassis 120 inches, and the normal loading space is 118 inches in the larger machine and 102 inches in the smaller.

The 1500-pound chassis has as a power plant a Buda motor with bore of 3.75 inches and stroke of 4.5 inches, which is rated at 22.5 horsepower by the S. A. E. formula. It is claimed by the maker to develop 25



The Valve Side of the Buda Motor Installed in the 1500-Pound Bessemer Chassis.

horsepower, and this is conservative. This motor is admirably designed and it is with the cylinders cast en bloc, with a large water jacket plate covering the top of the block. The motor is the L-head type with the valves at the right side. The crankcase is made in upper and lower sections, the upper carrying the main bearings, and the lower forming the pool for the splash lubrication. Below this is the oil reservoir. The motor is cooled by a thermo-syphon circulation of water through a radiator, and radiation is promoted by a fan driven by a flat belt from a pulley on the forward extension of the crankshaft. The lubrication is a combination system, the oil being pumped through a sight gauge on the motor and then to the oil pool in the base of the crankcase, where it is distributed by splash. The valves are enclosed by plates and all of the working mechanism is fully protected. The ignition is by an Eisemann high-tension magneto. The other details are practically the same, though the transmission gearset shafts are mounted on Hyatt roller bearings. The axles and wheels are somewhat smaller and the tires are 34 by 2.5 inches forward and 35 by three inches rear. The wheelbase is 108 inches and the loading space is 90 inches. The control members are identical and the brakes are internal expanding and external contracting on drums 13.5 inches diameter and 2.75 inches width. All of these machines are fitted with bodies to meet the requirements of the purchasers, and a considerable number of standard designs are always in stock, so that delivery may be made quickly.

The owners of Bessemer wagons in Boston and vicinity specifically, and throughout New England, generally, have the service that is afforded by a very complete station at 58 Church street, Boston, which is known as the Vulcan-Bessemer Motor Truck Branch. The building was completed late last year and was occupied in November. It is ideal in facilities and equipment and has space to store about 40 machines of differing sizes. While the attention given to those who desire that their machines have usual garage care is thorough and to a high standard, the provision made for service maintenance is with a view of meeting every emergency and requirement. The machine shop is equipped with every machine or hand tool desirable or necessary, and the stock of parts is as complete as that at the factories. The workmen are skilled and are experienced with Bessemer and Vulcan machines. This station is never closed and its resources may be depended upon as at all times available. The branch is in charge of Robert G. Howard, New England manager for the Bessemer Motor Truck Company and the Driggs-Seabury Ordnance Company, maker of Vulcan trucks, who is widely known and who has much experience with service station administration.

The Cranford Company, Brooklyn, N. Y., recently placed an order with the R. & L. Company, New York City, distributor of Garford trucks, made by the Garford Company, Elyria, O., for seven Garford trucks, to be used in asphalt paving work.

HOLLAND WITH ANDERSON COMPANY.

Storage Battery Expert Leaves Edison to Head Detroit Electric Research Department.

Walter E. Holland, who was chief engineer of the Edison Storage Battery Company, Orange, N. J., for a considerable period, and is one of the recognized storage battery engineers of the country, has retired from that position to become head of the research department of the Anderson Electric Car Company, Detroit, Mich. Mr. Holland associated himself with the Edison organization in 1902 and did a great deal of experimental and research work with acid and with the nickel-iron accumulator, known as the Edison battery, and his experience was of extreme value to him when he later on became a member of Mr. Edison's personal staff and engaged in research necessary in connection with electrical development.

Walter E. Holland, Head of Anderson Electrical Research Department.

Mr. Holland has perfected a number of important improvements in storage batteries and is regarded as an authority. He was appointed chief engineer in January, 1911, and continued as such until he resigned. He is widely known among electrical engineers and some of the papers he has presented to engineering organizations have been translated into several languages.

TRACTION PLOWS AND TRUCKS.

Pacific Metal Products Company to Enter Field in New Building at Torrance, Cal.

The impression has been gained by many persons that the new factory at Torrance, Cal., being erected at a cost of $100,000 for the manufacture of traction plows and motor trucks, is to be used by the Union Tool Company of that place, near whose plant the new building is being built.

The Pacific Metal Products Company, states, however, that this is erroneous. This concern is already operating a $100,000 plant in the production of its metal goods, and the new building is being erected for the convenience of the company in manufacturing its new line of plows and trucks.

SAURER 'BUS SERVICE.

Alpine Motor Company of Pittsburg Adopts Machine with Capacity for Thirty.

A large motor car, capable of seating 30 persons and modelled on the order of an ordinary trolley car, has been put in service by the Alpine Motor Company of Pittsburg, Penn. The machine is a five-ton Saurer chassis, made by the International Motor Company, the motor being 40 horsepower. The vehicle weighs 10,000 pounds and is capable of 25 miles an hour for any time desired.

The interior of the car is furnished with all the modern requirements for comfortable transportation and the riding of the car over rough streets is said to be easier to the passenger than in an ordinary trolley car. The machine is equipped with emergency, air and service brakes and is driven from a small compartment in the front end, separated by a glass partition from the passengers. Twenty gallons of gasoline, ample for a day's run, can be carried in a tank with which it is equipped.

NEW FACTORY FOR UNIVERSAL.

Company Now Incorporated Under Laws of Delaware with Increased Capital.

Announcement has been made by Fred K. Parke, secretary, treasurer and general manager of the Universal Motor Truck Company, Detroit, maker of Universal trucks, that the company has been incorporated under the laws of Delaware, the capital stock being $1,200,000, of which $500,000 is preferred stock and $700,000 common. All stock has been sold and work will be begun at once on the erection of a factory quite as large as the present plant.

The new building will adjoin the old one, the company having owned the entire square block of property since its organization. It will cost $250,000 without the machinery. According to Mr. Parke the Universal company will soon be one of the largest concerns in the world producing commercial motor vehicles and as the business increases other additions will be made.

ANOTHER BUILDING FOR SANFORD.

Increasing Demand for the Product Necessitates Plans for Doubling Present Output.

The Sanford Motor Truck Company, Syracuse, N. Y., maker of Sanford trucks, is increasing its facilities for greater output and has purchased of the Syracuse Savings Bank the three-story building at the end of West Fayette street. The purchase price is not named. At least 300 trucks, it is expected, will be made this year, more than doubling the output.

While the company at present has only about 50 men on its payroll, it is anticipated that between 200 and 300 will be employed before the end of the year. Last summer the corporation's capital stock was increased from $25,000 to $50,000 for the purpose of providing the additional facilities, made necessary by the increasing demand for trucks. J. Frank Durston is president of the concern and F. F. Sanford is secretary and treasurer.

SATISFIELD WITH POPE-HARTFORD.

Newark Coal Dealer Much Pleased with Initial Installation of Dumping Body.

Joseph H. Lucking, coal dealer of Newark, N. J., recently purchased a Pope-Hartford five-ton chassis, equipped with self-discharging body. The truck has a capacity of six tons and notwithstanding the adverse street conditions since its installation, it has delivered from 45 to 50 tons of coal daily with an average haul of five miles a load.

Mr. Lucking states that the truck has thus far exceeded his expectations. Delivery is made from the right side. The body is elevated and the coal is discharged almost noiselessly on account of the steady flow. The entire six tons can thus be unloaded in less than two minutes. Mr. Lucking has ordered a three-ton truck of similar design to be delivered in a month and he will dispose of his horses as soon as he can replace them with motor equipment.

G. V. MACHINES IN THE PHILIPPINES.

First Installations Have Demonstrated Their Value and Additional Orders Are Now Being Filled.

The first electric wagon used in the Philippine Islands was a General Vehicle machine, which was utilized about Manila. The highways about the islands at best can be regarded as poor roads, and generally they are cart paths, but in and about the principal cities there are very good streets and in some instances ways good enough to be classed as boulevards. The first electric vehicle was a ton capacity, and this was used practically in the city of Manila.

The United States War Department then purchased several machines and has added to that number until it now has 19 in service, all of which are employed in the haulage of supplies, etc., for it is a work of no small proportions to regularly distribute these. Four machines were bought by business houses for private use, and these were used with the same satisfaction as those in government service.

The company is now producing 16 other machines of differing capacities, which will be sent to the Philippines early in the present year, which will increase the total of General Vehicle wagons and trucks in the islands to 39. The utility of electric machines has been so positively demonstrated that it is believed that the number will be considerably augmented during the present year.

DEVELOPING RAILROAD BUSINESS.

South African Railways to Adopt Motor Road Transport in Lieu of Branch Lines.

According to information from South Africa, the general manager of the South African Railways has developed a new plan for developing business in the outlying sections, where the demand for transportation is held to be insufficient to warrant the construction of branch railroad lines at present. Several such districts are said to be rich in productiveness, were it possible for them to be placed in regular communication with railway service.

The plan considers the establishment of a motor road transport operating two types of vehicles, one for passengers, parcels and mails, and the other for heavier freight, with a speed of from 12 to 20 miles an hour. A telephone will parallel the road and the whole service, as far as possible, will be conducted in accordance with railway methods. In each case it is proposed to build a branch line as soon as the extent of the traffic is sufficient to justify such action.

The MOTOR TRUCK

Devoted to Motor Driven Business Vehicles of All Classes.

VOL. IV. PAWTUCKET, R. I., APRIL, 1913 No. 4

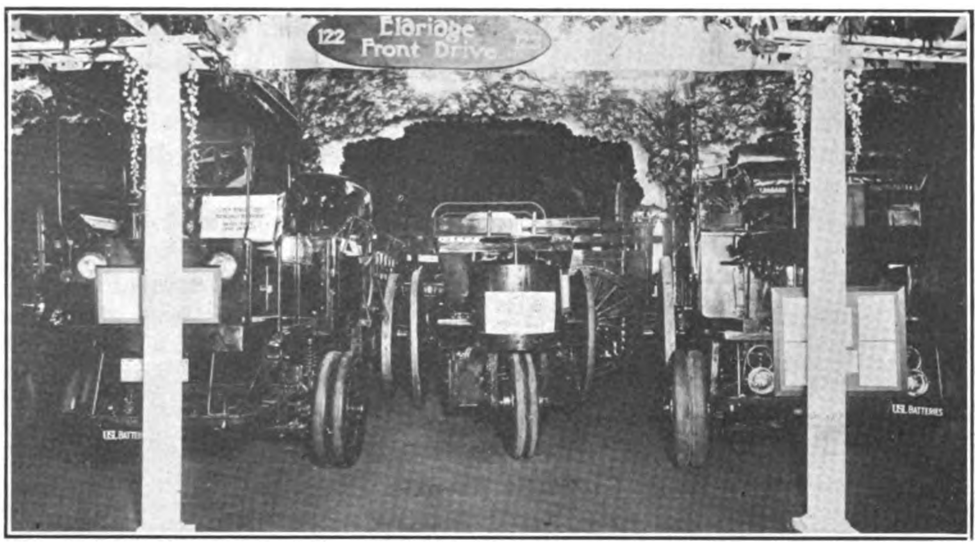
BIG BUSINESS AT BOSTON'S TRUCK SHOW.

Directors Vote Before the Close to Hold Similar Exhibition in 1914---Two New Makes of Both Electric and Gasoline Machines Are Shown, with Many Seen for First Time in New England---Fine Display of Body Designs.

MEASURED by the volume of business transacted and the interest manifested in power vehicles, the second exclusive exhibition of the Boston Commercial Motor Vehicle Association, held at Mechanics' building, in that city, March 19-26 inclusive, was without question the most productive of the service wagon shows held during 1913. If one were to judge from long range and consider as principal factors the number of exhibitors of machines, or even the aggregate of vehicles displayed, there might be issue taken with this statement, but the best judgment is that of the exhibitors, many of whom are members of the association, and so satisfied were they with the results that before the conclusion of the show it was voted to have a similar exhibition in 1914.

While the executives of the national organizations that have directed the exhibitions in New York and Chicago have decided to discontinue the exclusive shows of wagons and trucks in those cities, the Boston association has voted unanimously to continue, and with no change in policy other than to reduce the interval between it and the pleasure car exhibit to a single week day. That is, the Sunday and Monday after the close of the pleasure vehicle show will be given over to removal of the exhibits and the installation of the power wagons in the stands. This will permit the closing of the exposition on Saturday evening, and give five full days, instead of six full days and seven evenings, with a Sunday intervening.

The principal reason for this change is to minimize the demands made upon the exhibitors who have their local business as well as show interests to give attention to, and who have found that in addition to the shows the necessary preparation for and the accumulation of work during their progress makes it imperative that the exhibits be confined to two weeks. There was no question as to the productiveness of the show from many viewpoints, and the results will undoubtedly be realized in very large measure by all exhibitors who have representatives in the section from which the visitors were attracted.



The Eldridge Front Wheel Electric Driven Machines, Showing the Single Wheel Dump Cart of Two Tons Capacity, an Entirely New Production.

If there is to be a criticism of the service wagon display that is to follow an exhibition of pleasure vehicles, it is in the fact that it is impossible in the short time to so arrange the exhibition spaces as to give to the exhibitors the floor area often desired. Where both pleasure cars and service machines are made by the same concern, what might be sufficient to show the passenger types might be entirely inadequate to give a satisfactory display of the freight wagons, and where the stands are primarily allotted for the first display, and they cannot well be greatly changed for the second, the only possibility of

The Display of the Knox Automobile Company, Which Was Principally Made Up of Fire Apparatus and Knox-Martin Tractors and Equipment.

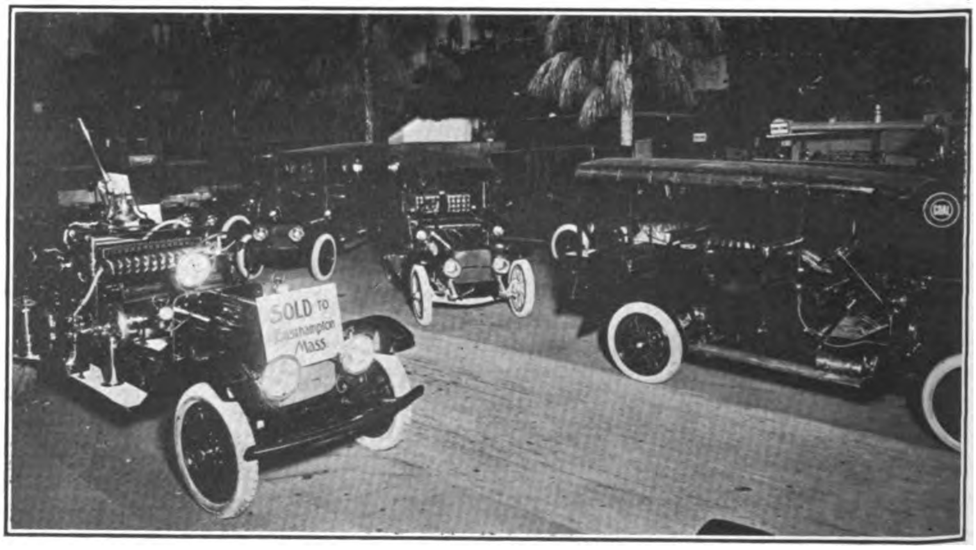
The Boston show for 1913 was in every way a success. There were in all 57 different makes of machines shown, and there were in all 219 chassis, of which about 85 per cent. were equipped with bodies. It will be seen that while there were less makes seen than at either New York or Chicago, it was the largest exhibition ever held under one roof, and this was a decided advantage from the viewpoint of the exhibitors, for where time is limited it was possible for a visitor to see every type he cared to and he had the opportunity for comparison without leaving the building.

If there was one thing more than another impressed upon the observer it was the manner in which concerns that are investigating the possibilities of motor vehicle equipment study the machines in the market. While it would be practical to examine the machine in the salesrooms of the agents and branches at leisure, many firms sent to the Boston show the best engineers or mechanics in their employ with instructions to see all vehicles that might be suitable for the requirements and make special report on them. This necessitated the systematic examination of different vehicles of certain types, and in some instances these men gave several days to the investigations. It would not have been possible to have gathered the same detail or reached the men capable of giving the information in a very much longer period. It is absolutely impossible to reach any conclusion as to the business that was developed in this manner, but it is certain enough that when concerns take the care to obtain expert knowledge, or at least the judgment of men who may be depended upon, it is not from idle curiosity.

insuring a sufficient space for the second is by taking the desired area for it for both shows.

To do this means perhaps a larger expense than was intended or desired, or this prospect may mean the reduction of the space for the second show at a considerable inconvenience. As the space is generally applied for months ahead of the show there is small probability of making exchange in the event of a determination to forego display. It is impossible to have the stands without demarcation, and to make a material change would entail expense for the management. Regarded from any point of view it is not feasible to arrange for two successive shows, each of a different character, to obtain the same results were each exhibitor free to select the space desired, as in two separate exhibitions. Not only this, the exhibitor showing at both displays is ordinarily considered before the one desiring but one stand, and this sometimes limits the space that is available for those who can exhibit only at the second.

While these conditions were experienced to some extent in Boston, there was by no means the same results as in New York and Chicago, for in this the members of the association are entitled to whatever space may be desired, and no stands are allotted to non-members until members have first had opportunity to make application. The members of the national association have the first choice without reference to the agencies or branches in New York and Chicago, and after these applications have been provided for the others are considered. It will be understood that the Boston association members share the profits or assume the loss, and with the other shows the national body is the gainer or the loser.



A Section of the White Exhibit, Showing a Combination Hose and Chemical Wagon of Unusual Design That Attracted Much Attention.

The Stand of the Pierce-Arrow Motor Car Company, Where Was Shown the Well Known Worm Driven Machines, the Largest of This Type Exhibited.

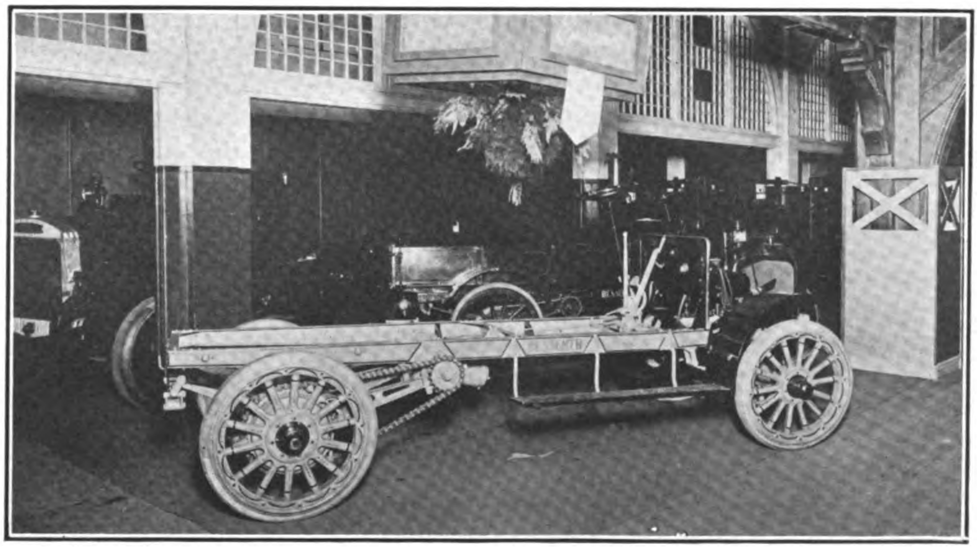
Another fact equally impressed upon the observer was that many firms that have motor vehicle equipment are desirous of obtaining all the information possible of machines that meet their requirements, because additional purchases are contemplated, and buying is governed by first hand knowledge. That is, concerns that have perhaps all the vehicles that will be used the present season believe it well to have precise detail of the machines that would be suited to their purposes, with a view of economizing time and accurately judging all from which choice can be made. Motor wagons are bought by the best measure of value the business man may have, and quality and utility are two elements that are given consideration.

There is no place where the information desired by a man who wants motor vehicles can obtain it as readily or as economically as at a show, which application is made to mechanical detail and construction, and the majority of buyers are willing, when dealing with a manufacturer of reputation or his representative, to accept statements as to materials and to judge construction, design and workmanship by the machine. But what is very often an unknown quantity is the character of service that will be afforded, or perhaps the assurance of co-operation in the maintenance and upkeep of the vehicle. This is a decidedly important factor with many buyers, and it is not an exaggeration of fact to assume that it will become even more potent in its influence.

Considering all qualities and values equal there is no doubt whatever that the character of the service afforded the owners of vehicles will be a very important reason for selection, and when both quality and service are considered it will be understood that nothing but actual worth and satisfying attention will meet the requirements of the day. The man who is making an investment in service wagons is just as desirous of making dividends upon the money it represents as in any department of his business, and buying is not influenced by sentiment or fancy. In other words the experience with the Boston show demonstrated that quality and service are first, and while the former can be ascertained from the vehicle, the latter must be learned from observation and from the experience of others.

The Boston exhibits were in a number of instances machines that had been shown at New York, Chicago and elsewhere, but a considerable number, and this was a very wise character of display, were machines with body equipment built to meet the requirements of different service that were sold and were to be delivered directly after the exhibition. The showing of the vehicles selected and ready for the work they were to do was not without its influence with those in similar lines of business seeking information. There were, of course, many bodies that might be regarded as standard in type, but of these a large number were built to specifications for certain work, and proportioned with reference to the chassis design, and examination of these afforded those desiring it exact knowledge of specialized vehicles.

There were not as many heavy trucks seen as at some of the other shows, for there was apparently a belief that the greatest demand is for the light and fast delivery vehicles, and there were comparatively few novelties. The showing of quick unloading bodies was very good, but the majority of those seen had been



The Bessemer Delivery Wagons and the Vulcan Trucks, the Last a New Vehicle, Which Were Noticeable for the Constructional Features.

shown at previous exhibitions. This does not mean that there was less interest in such equipment, but it does mean that in several instances power and manual hoists for dumping bodies were rejected for bodies that were specially built for Boston service. There were several bodies designed for lumber haulage, and of these one was seen at New York and Chicago, but the others were adaptations of well known constructions and were not new.

The exhibition was made up of 219 chassis, of which about 85 per cent. were fitted with bodies, and there were in several instances displays of parts or complete group assemblies of components, but with rare exceptions it was not believed necessary to have the elaborate showing of chassis members, once a feature of every vehicle show. Unless there was unusual construction the assembled chassis was regarded as sufficient. For those who really desired to give attention to detail of chassis construction the full body equipment was more or less or an inconvenience. One exhibitor solved this problem by showing chassis from which the bodies had been removed and were shown beside them, sufficiently elevated so they could be examined conveniently.

A Glimpse Along the Main Aisle in Machinery Hall, Showing the Stand of the General Vehicle Company, the Largest of the Kind in the Exhibition.

There were in all 57 different exhibits and 58 different makes of machines, the General Motors Truck Company showing both gasoline and electric vehicles. The exhibitors of gasoline wagons and trucks numbered 49, the electric displays were eight in number, and there was one exhibit of steam machines. The makes shown were as follows: Gasoline, Adams, Alco, Atterbury, Autocar, Bessemer, Best, Brown, Buick, Chase, Decatur, Federal, Flint, Garford, G. M. C., Gramm, Hupmobile, I. H. C., Jeffery, Kelly, Knox, Koehler, Lauth-Juergens, Lippard-Stewart, Little Giant, Locomobile, Maccarr, Mais, Marmon, Mercury, Overland, Packard, Peerless, Pierce-Arrow, Pope-Hartford, Reo, Sanford, Selden, Smith-Milwaukee, Sowers, Speedwell, Standard, Stewart, Sullivan, Universal, Velie, Victor, Vulcan, White and Willys; electric, Atlantic, Buffalo, Couple-Gear, Edison, Eldridge, G. M. C., G. V., Waverley; steam, Stanley.

The gasoline vehicles numbered 191, the electric 23 and the steam five. The largest number of machines shown by any one maker was 26, these being Packards, and the next in point of number was the White, of which 16 were displayed. The Autocar stand contained 10 wagons, and the Kelly and the General Vehicle exhibits were of eight each. The Lauth-Juergens, the I. H. C., the G. M. C., the Garford and the Knox showed six machines each; the Alco, Stanley, Stewart, Peerless, Lippard-Stewart and Pierce-Arrow five each; the Pope-Hartford, Brown, Federal, Velie and Eldridge four each; the Reo, Universal, Koehler, Selden, Bessemer, Sanford, Mercury, Atterbury, Chase, Decatur, Locomobile and Speedwell three each; the Standard, Waverley, Adams, Little Giant, Jeffery, Victor, Vulcan, Sullivan, Buick, Edison and Couple-Gear two each, and the Mais, Gramm, Willys, Overland, Hupmobile, Flint, Best, Buffalo, Atlantic, Marmon, Sowers, Smith-Milwaukee and Maccarr one each.

The machines that were shown for the first time in Boston included the Adams, Best, Brown, Buick, Flint, Hupmobile, Jeffery, Lippard-Stewart, Little Giant, Marmon, Mercury, Overland, Sanford, Selden, Smith-Milwaukee, Sowers, Standard, Stewart, Sullivan, Universal, Vulcan and Willys, in the gasoline vehicles, and the Buffalo and Edison in the electrics. The Atlantic trucks were shown for the first time in Boston at the electrical exhibition last autumn. The constructions seen for the first time were the Sowers, a Boston-made machine; the Edison, which is built at Lawrence, Mass., and the Marmon, while a new type of vehicle with familiar propelling power is the front-wheel driven Eldridge dump cart.

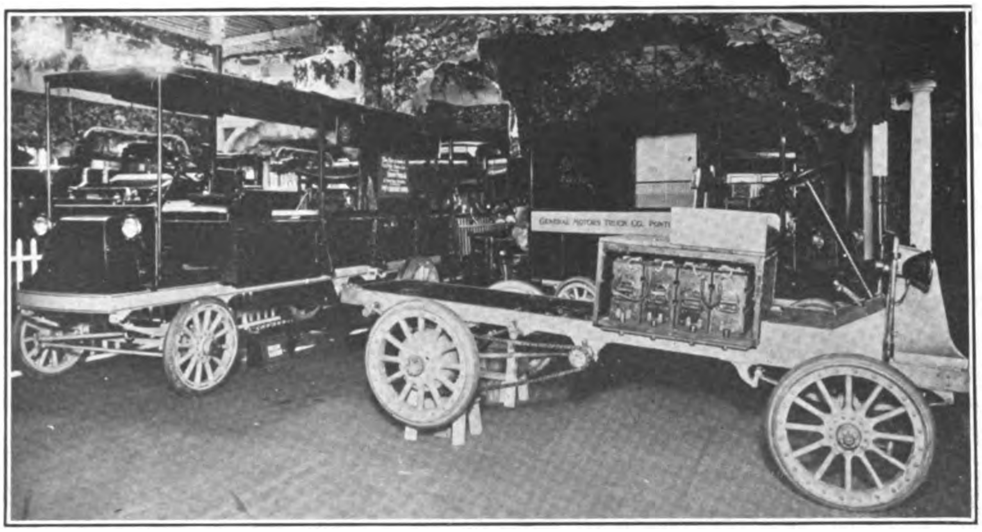
Considering the machines having initial exhibition in Boston the entire number shown aside from the Standard, Vulcan and the Smith-Milwaukee were what would be included in the light classification, no one exceeding two tons capacity, and the majority ranging from 1000 to 3000 pounds. Several makes are produced in larger sizes than were shown. There appeared to be a prevailing opinion among exhibitors that there is a more productive market for the lighter vehicles, from the fact that so many of these types were seen.

The exhibits including quick discharging bodies for heavy loads were those of the Alco, Garford, G. M. C., Knox, Locomobile, Peerless, Packard, Pierce-Arrow, Speedwell, Velie and White, in the gasoline machines, and the Eldridge in the electrics. The majority

of these vehicles were equipped with hoists, some of which were power driven. All of the hoists were of the types that have been adopted by the makers as standard and are generally exclusively controlled by the builders of the machines. Some of these are comparatively new, but aside from the latest power hoist of the Peerless trucks all have been described. The device is a rack and pinion construction, the racks being arched in form and coupled to the bottom of the body near the forward end. With the body lowered these are carried parallel to the forward ends of the chassis frame side members. The power is transmitted through the driving shaft and spur and bevel reduction gears to the spur gears that engage with the racks, and the control is by a lever at the driver's seat. The hoist is fitted with an automatic stop when it reaches an angle of 42 degrees and the full inclination can be reached in about 30 seconds under normal conditions. This was shown on a five-ton chassis, but it may be fitted to other sizes. The other power hoists were of the worm and nut, or shaft and chain type, save the Pierce-Arrow, which is a hydraulic construction. This was seen for the first time at New York.

The Locomobile display included a removable dumping body that is carried on rolls that fit heavy channels mounted on the chassis frame, and is moved backward and forward on the chassis by a worm shaft and nut. The intention is to use these with a loading platform from which the bodies may be taken when loaded and on which they may be placed when empty, that the chassis can be kept moving with the least delay necessary. This same construction was seen at New York, but at that time there was a platform body designed for lumber haulage with five tons capacity. The majority of the dumping bodies were of steel and while they differed in dimensions they were proportioned to the requirements of the chassis.

One of the most interesting exhibitions was that made by the Eldridge Manufacturing Company, which is agent for the Couple-Gear trucks and tractors and is builder of the Eldridge front-wheel drive vehicles. These are generally designed for heavy haulage. The novelty was the single-wheel driven dumping cart built for the Metropolitan Coal Company, which now uses six of the five-ton carts driven by the front wheels. The Couple-Gear wheels are used and the machines are adapted for the needs of the purchasers. The single-wheel cart is a big tricar in design with the load carried on large steel tired wheels. The front wheel is mounted in a cast steel yoke that is not unlike a bicycle fork and the head of this fork is fitted to a heavy steel member installed in the angle steel frame. The fork has a plain bearing in this member and is maintained by a large nut. The fork is turned by a hand wheel. The Couple-Gear wheel is built with a fixed axle with a large contracting band brake at either side. The cable connection is flexible. The steel channel chassis frame extends from the "head" of the front wheel back of the rear axle, which is of steel, and from this the battery box cradle is suspended, there being helical springs at the corners to protect it against shock. The body is mounted on a shaft that is also carried on helical springs, which eliminate rattle when the vehicle is driven unloaded. The body is coned from the rear to the centre of the bottom, and when dropped this line of the cone is at an angle of 90 degrees. The driver's seat is installed on full elliptic springs. The capacity of the wagon is two tons and it is intended for doing the work that a single animal would do. Because of the very short wheelbase it may be worked in space where any other machine would be useless. A machine of this type was built for the Third Avenue Railway Company of New York by the chief engineer of the company, and it has given admirable service, having ample power for a load of two tons on streets with grades up to 8 per cent., and having a radius of movement of approximately 25 miles to the battery charge.



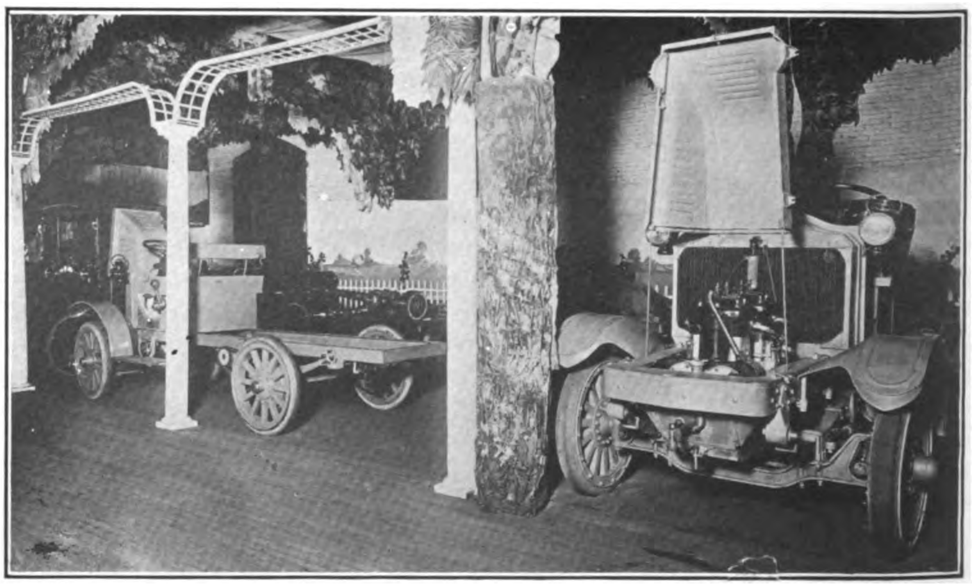
The Combination Display of Gasoline and Electric Machines Made by the General Motors Truck Company, the Only One of This Character in the Building.

Another interesting construction at this exhibit was a bottom-dumping Watson wagon of five tons capacity fitted with front wheel drive, built for the Rowe Construction Company of Boston. The battery is carried on the chassis, giving large road clearance, and back of the body is a large tool compartment. The Eldridge company also displayed a Couple-Gear tractor with trailer, built for the Curtis & Pope Lumber Company of Boston. This was conventional construction, but the high trailer has a standard forward on which is mounted a ratchet operated roller, and on this and a floating roller at the rear the load is carried. The rollers afford a means of quickly dropping load when ratchet is released. The tractor battery is underslung.

General Vehicle Chassis on Which Is Installed an Animal Wagon Body Used by George B. Hart for 16 Years, Adapted for a Retail Butcher Service.

The Sowers 3000-pound delivery wagon, built by the Sowers Motor Truck Company, Boston, seen for the first time at any show, is designed by Charles Basle, formerly a driver of racing cars. It is well thought out and follows conventional practise in every way. With the motor under a hood type the wheelbase is 140 inches, and with the motor under the footboards it is 120 inches, the loading space being the same with both. The motor is a Wisconsin with cylinders of 3.75-inch bore and five-inch stroke cast en bloc, with the valves enclosed, built for heavy service and conservatively rated at 25 horsepower by the maker. The cooling is by thermo-syphon circulation, a square tube radiator and fan. The lubrication is by a gear pump through a system of tubes to all bearings and by splash, the flow of oil being through a sight gauge. The ignition is by Bosch high-tension magneto. The carburetor is an automatic float feed type. The clutch is a leather faced cone with auxiliary springs, the transmission gearset a selective sliding gear construction with nickel steel shafts and gears, having three forward speeds and reverse. The drive shaft has two universal joints. The jackshaft is heavy, with large shafts and differential contained in a pressed steel housing. The drive to rear wheels is by side chains. The frame is a reinforced nickel steel channel, 4.5 inches width and four inches deep. This is carried on semi-elliptic springs forward and a platform construction at the rear. The rear axle is nickel steel and the forward axle an I section, both fitted with New Departure bearings. The brakes are external contracting on and internal expanding in drums on the rear wheels. The right side steering gear is a worm and nut type. The control levers are conventional. The wheels are 36 inches diameter, with 3.5-inch solid shoes forward and four-inch shoes rear. The purpose of the company is to make but this size of machine.

The Edison electric machines, made by the Edison Electric Vehicle Company of America, Lawrence, Mass., were shown in 1500 and 3000-pound sizes, and these had been hurriedly completed for the exhibition, so that they illustrated design rather than the perfection of detail. In both of those shown the drive was by worm and gear, but this or the conventional side chains is optional with the purchaser. The worm and gear are the David Brown design and make and are imported, but the full floating rear axles are built by the Standard Roller Bearing Company. There is a universal joint in the driving shaft and the motor is suspended from two brackets mounted on heavy frame members. The drive in the smaller machine is through the rear springs, the forward ends of which are fixed in the spring hangers, and a radius rod of skeleton type preserves the relation of the motor and the rear axle. The radius rod is pivoted so as to swing at the forward end. In the 3000-pound size the drive is through radius rods, with the springs shackled in the customary manner, but there is a radius arm that extends from the rear axle forward to a coupling mounted on a solid frame member. In the 1500-pound wagon the forward suspension of the frame is a platform spring, the forward ends of the side members being fixed in the spring horns, and the rear ends are shackled to a cross spring carried on a frame cross member. The effect is decidedly unusual. It is claimed for this that the machine is extremely easy riding and that considerably less current is required to drive it. The power is furnished by General Electric motors for all machines, and by Edison batteries, the battery cradles being underslung, but that of the small wagon is loaded from the top through a trap in the floor, while the larger size wagons load the batteries from the sides.



A Part of the Stand Where the Kelly Trucks Were Displayed, These Being the New Type with Water-Cooled Engines and Flexible Frames.

While this is the first display made by the company the machines have been used for four years and are said to have given excellent satisfaction.

The Jeffery delivery wagons, which are of 1500 and 2000 pounds capacity, were shown for the first time in the East and were especially interesting. The 1500-pound chassis is practically the Thomas B. Jeffery Company's pleasure vehicle design, strengthened for heavy service, with the same motor used in the pleasure vehicles, but the 2000-pound vehicle is a new design throughout, and while conventional is thoroughly practical. The lighter machine is driven by shaft, but the larger power transmission is by double side chain. The wheelbase of both is 120 inches. With the small chassis the load is carried with 40 per cent. on the forward axle, but with the larger 75 per cent. of the load is on the rear axle. Both have right side drive and the control is by the usual levers.

The Marmon light delivery wagon, built by the Nordyke & Marmon Manufacturing Company, which was shown for the first time at any exhibition, attracted much attention. The motor is the Marmon design with four-inch bore and five-inch stroke, of the T head type, and it is fitted with a governor that controls a throttle valve in the intake manifold. The maximum speed is 20 miles an hour. This governor may be sealed. The motor has all the Marmon features, with the heavy crankcase and the Marmon system of lubrication. It is mounted at three points and with a slight inclination to insure a straight line transmission of power. The ignition is by high-tension magneto and battery, using one set of spark plugs. The clutch is a cone, faced with anti-friction material. The drive is by shaft with the transmission gearset incorporated with the rear axle. The rear axle is a full floating type with a single ball bearing of large size mounted in the centre of each wheel hub. The front axle is an I section. The frame is pressed steel channel section and is carried on full elliptic springs at the rear and semi-elliptic springs forward. The wheelbase is 120 inches and the wheels are 32 inches diameter, fitted with 32 by four-inch tires, single pneumatic forward and dual pneumatic rear, but solid tire equipment is optional. The drive is right side with the usual lever control, with service and emergency brakes of the internal expanding type operating within 16-inch drums on the rear wheels. The design throughout is admirably developed.

The other vehicles shown were displayed at the New York or the Chicago shows and, while in every way interesting, do not call for special attention in this review. The Stanley steam machines, always shown at Boston, were the only vehicles of this type seen at any of the shows throughout the country. The chassis were fitted with bodies of admirable design and finish and were notable from the fact that they were the equal of any seen in the exhibition.

The showing of fire apparatus was not extensive, there being a White combination hose and chemical wagon, a Knox hose and chemical wagon and a Knox pumping engine, a Kelly hose and chemical wagon, a Federal hose and chemical wagon and a Pope-Hartford hose and chemical wagon. All of these were especially interesting, the White machine having a body design in which the entire space below the top of the sides is given over to hose storage and carrying space, while above this, in the centre, is a longitudinal seat for the men, in which can be stored their clothing, etc.

Of the special body constructions shown, one that attracted much attention was mounted on a Peerless chassis and is to be sent to Porto Rico, where it is to be used in passenger transportation. The chassis is three tons capacity and on this is a platform with a standing canopy having seven stanchions at either side. There are five transverse seats, each of which will seat six persons, and there are two longitudinal seats at the rear with a space for baggage between them. The capacity is 40 persons, and at either side are two long running boards so that passengers can enter or alight from any seat. These steps may be raised and folded when the machine is under headway. The purpose of the owner is to place the machine in service that will give it a run of 120 miles each day, making a round trip in two days.

An Alco 6.5-ton chassis with tank for the haulage of tarvia products and the application of tarvia to road surfaces, built for the service of the Barrett Manufacturing Company, was prominent among the exhibits. The company has had trucks in service for two years. The first were fitted with tanks into which the tarvia was loaded at the works at Everett and thence hauled to the work, where they were hauled behind steam rollers, hose connections from the boilers giving heat to liquify the tarvia and a sufficient pressure to force the tarvia through spray headers on to the roadways under construction. The next were fitted with power pumps, driven from the transmission, that forced the tarvia from the tank at a pressure of 100 pounds, and gave a control to the application by the variance of the pressure. The machine exhibited has an apparatus that is much improved and in which the pump may be used to fill or empty the tank, and there is a coil of pipe through which steam may be forced to heat the contents in the event of cooling from a long haul.

There was a very large showing of service vehicle tires, practically every concern of prominence being represented, and in these there was a decided interest. The number of accessory exhibitors was 60, and these were generally those of supplies and equipment, there being but very few part makers represented.

John A. Graham, formerly sales manager for the Westfield Motor Truck Company, has been appointed district manager for New England for the Sanford Motor Truck Company, Syracuse, N. Y., and will make his headquarters at Boston. Mr. Graham was formerly a resident of Boston and is widely and favorably known to the trade.

NEW CHASSIS CONSTRUCTION DETAILS.

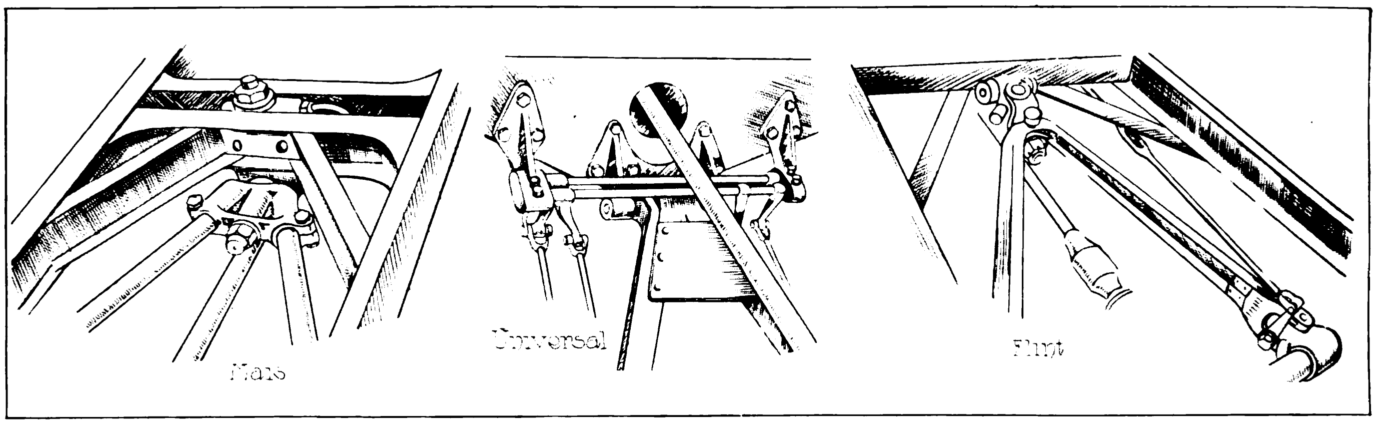
Increased Length and Lowered Forward Ends of Radius Rods Lessen the Upward Thrust of Tractive Effort and Minimize Tire Wear---Some Improved Radiators.

THE majority of manufacturers of service vehicles are disposed to adopt what has been found to yield satisfactory service as a standard, and to develop the construction in such details as experience justifies. This does not mean that progression is lost sight of, but it does emphasize that it is far better judgment to first have a design that will have power, endurance and economy, and then work out improvement of detail that will simplify and strengthen wherever possible or practical. It is natural enough that each designer should study his own work, and observation of many vehicles will demonstrate possibilities that might not be realized with one or several. Not only this, it often requires a considerable period of service to establish conclusively that a change could be advantageously made, and an improvement is seldom determined until after a careful consideration of the needs and the results are accurately estimated.

There will undoubtedly be wear with use, and wherever there is movement the intention is to provision to minimize loss through wear may be another way of putting it.

The tendency has been to increase the proportions of components that are subjected to great strain or sudden stresses, and which may be weakened by the continuance of vibratory shocks. There has been realization that such parts may be seemingly perfect and yet the material not be up to the standard. The design may not endure because of unforeseen conditions, and there may be other reasons why a change should be made. These necessities have brought about what are referred to as refinements and improved details, but it may be accepted that the purpose of the designer is to remedy conditions that should not continue to exist.

This statement should not be understood to be criticism, but it is to emphasize that every designer is making his machine better when necessity or desirability impels a change. Improvement should not be regarded as confession of fault or weakness, and there



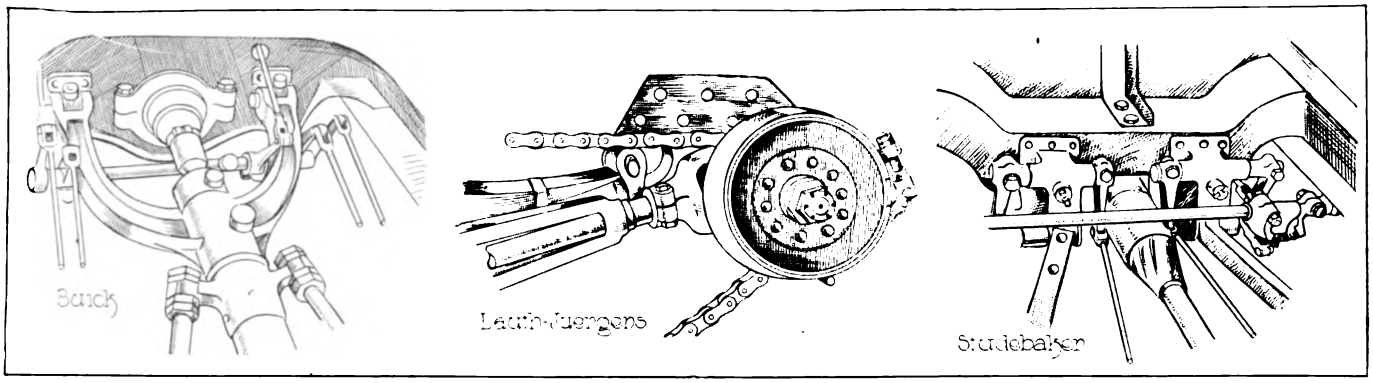
The Perfected Thrust Block of the Mais Design, the Forward Radius Rod Ends of the Worm Driven Universal Wagon, and the "Triple-Acting" Radius Rod of the Flint Machine.

vide means of lubrication and to have the bearing surfaces sufficiently large so that the destructive action will be slow, while adjustment that will compensate for lost motion is absolutely essential. These conditions can be provided for without material observation, but there are others that cannot well be determined. These must be noted and sometimes effects can only be learned save under unusual and peculiar circumstances.

Frequently a construction may be regarded as in every way adequate to the requirements, and it may be in every way correct from an engineering viewpoint, but the assembly may be such that time may be lost in giving attention, in making adjustment, in making replacement, or other necessary work. This has led to what is summarized under the term of simplification, or perhaps accessibility, while lessening of expense with reference to cost of parts, or additional is no reason for condemnation of what has previously been produced. Yet it cannot be accepted that a change has eliminated every chance of further perfecting.

In examination of the different machines, unless one is familiar with the constructions, there may be apparently little if any difference as compared with the models previously produced, but with knowledge of the improvements the attention to development is apparent.

One of the details that is given very general attention is the construction of radius rods, and there is seemingly an increased tendency to lessen the angle of inclination that there may be a more direct forward driving thrust. This is to be noted with many of the shaft driven machines, and to some extent with those in which the drive is by side chains. The vehicles in which the shaft is used are generally those where the



The Enlarged Torque Tube Yoke of the Buick Delivery Wagon, the Jackshaft Bracket of the Lauth-Juergens Truck, and the Radius Rod Coupling of the New Studebaker 3.5-Ton Truck.

system is the concentric gearing, such as the Mais, the Brown, the Piggins, the Lord Baltimore, the Studebaker, the Atterbury, and with the worm driven Universal, although there are constructions in which the chains are used where the forward ends of the rods are dropped by using longer jackshaft hangers so that when a load is to capacity the normal driving effort is exerted in what may be regarded as a straight line.

Though the speed of the service vehicle may be comparatively slow and the springs of the machines so designed that there will be gradual deflection or reflection, there will be the vertical movement of the rear axle proportionate to the inequalities of the road surface. The tractive effort is assumedly the same and the angularity of the thrust is dependent upon the degree of movement. The longer the rod the less the degree of angularity and the upward thrust. The change of driving effort has a decided effect upon tires, for there is a greatly varied stress upon them, and this is in every way different from that of load carrying. This constant variance, however, is not generally considered with reference to tires, but to the chassis. Lengthening the radius rods and coupling them to frame members causes the thrust to be directed more longitudinally, and there is not the "lift" in the centre of the chassis frame that would cause extreme strain, especially when the load is, in great part, back of the radius rod connection.

In the Mais construction the chassis frame is designed with two cross members well forward, between which is set a special block or fitting. The rear cross member is reinforced against the forward thrust by heavy channel diagonals from the centre to either side member. The thrust block carries a large socket, into which is fitted the globe of a short shaft, and on this shaft is mounted a yoke. In the ends of the yoke are sockets, into which are set the forward ends of the radius rods, clamping bolts affording means of adjustment when the relation of the rear axle has been determined. This yoke is pivoted on the shaft so that the movement of either end of the rear axle is not resisted, and the globe and socket connection permits the vertical action of the axle without stress. The globe and socket joint is lubricated by two large grease cups connected with the block by heavy copper tube.

The Studebaker construction differs from this in that there is a heavy centre frame cross member, mounted in the channels of the side members and dropped to lower the long radius rod ends. The driving shaft is under this member and at either side of the shaft secured to the member are two large brackets. The radius rods are mounted in the lower part of these brackets and in the top of each is a small shaft with a long bearing to the ends of which are clamped two lever arms. The arms project downward. To the outside arms are attached the forward pull rods, and to the inside arms are secured the rear pull rods of the linkage of the two transmission brakes, this construction giving a direct draw of the rods in line with the shaft. The radius rods have a free motion with the vertical movement of the rear axle.

In the Universal worm driven ton wagon the centre

The Torque Lever of the Stegeman Wagons and Trucks, the Radius Rod of the Hercules Machines and the Vernier Adjustment of the New Bessemer Chassis.

cross member is a wide web in which is a round hole through which the shaft extends. Below the hole and under the shaft is a large bracket with two ears or lugs wide apart. The radius rods are of angle steel connected at the forward ends by a wide gusset plate, and ahead of this is mounted between the ends of the rods a fitting. A shaft extends through the lugs of the bracket and the fitting, on which the rods may move freely with the movement of the rear axle. At either side of the central bracket are two others, and in these are mounted the shafts for the service and emergency brakes.

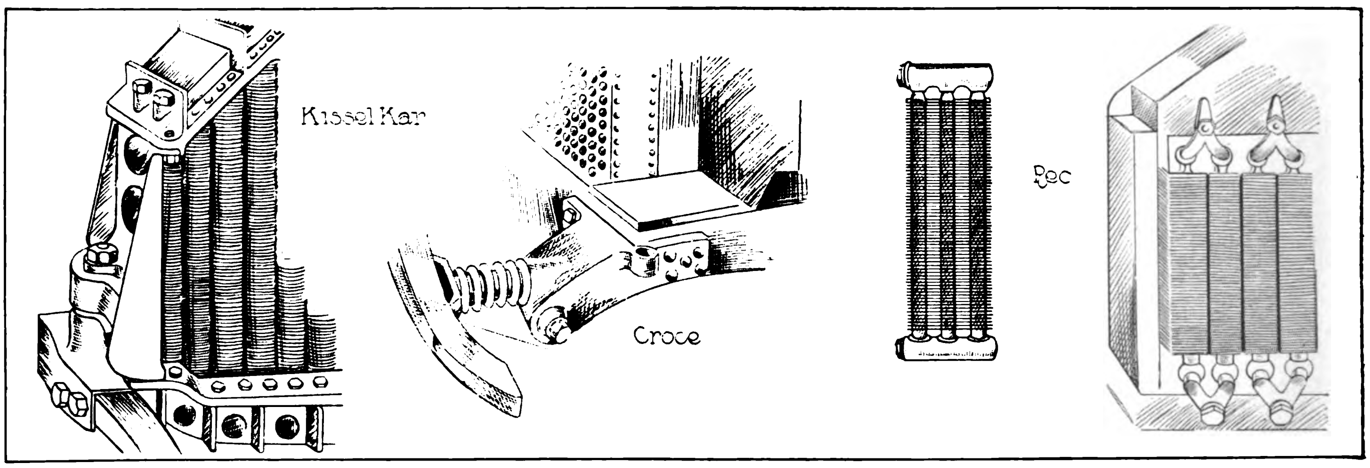
The radius rods of the Flint wagon are steel channels with yokes at the rear ends, the forward ends being joined by a heavy curved member, through the centre of which is a yoked fitting, in which is a shackle that is mounted in a yoked bracket carried on the centre frame member. The coupling allows a transverse and vertical motion, and the rods may also twist on the supporting member, eliminating every probable stress. The yoked rear ends are connected with the rear axle so that a transverse movement is possible.

The Buick delivery wagons are built with the driving shaft enclosed in a torque tube that has a large, wide yoke with the ends carried in brackets on a large frame cross member, pivoted to allow a free vertical movement of the rear axle, and directly behind the yoke is a fitting in which the forward ends of the radius rods are secured after adjustment as to correct relation. The construction is not new, but it is extremely heavy and intended for endurance in service. Beneath the ends of the torque tube yoke are brackets that carry the brake shafts, with the forward pull rods extending through holes in the frame cross member.

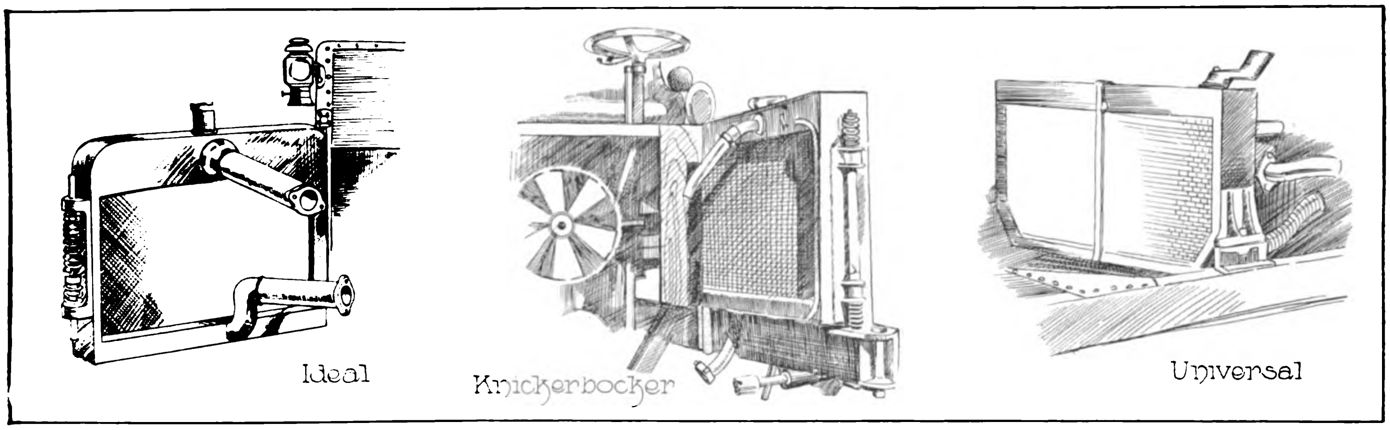
The 1500-pound Maccarr wagon chassis has a torque rod that has round upper and lower members to secure lightness. The forward end is shackled to a member mounted in a bracket on a frame cross member that is carried between helical springs. The rod moves at the rear end with the rear axle and is free to turn on the shackle at the forward end, and the possibility of vibration is taken by the helical springs and the thrust is very nearly direct at all times.

In the Stegeman machines of one ton or more capacity the starting and braking stresses are taken care of normally by the pressed steel chain cases that serve as radius members, but in addition to this there is a torque lever, so-called, that is swivelled at the left side of the differential housing of the jackshaft and is coupled to an upright member supported by a bracket on the centre frame cross member, this vertical member having a slight movement in a guide between helical springs. This is expected to resist extreme strains and protect the differential gear and driving shaft.

The Bessemer wagons have an adjustment for the forward ends of the radius rods in the jackshaft hanger in the form of an eccentric and a vernier arrangement



The Aluminum Radiator Frame of the New 2500-Pound KisselKar Delivery Wagon, the Expanded Tube Cooler of the Croce Vehicles and the Sectional Radiator of the 3000-Pound Reo Machine.



The Swinging Radiator of the Ideal Machines, the Hinged Construction of the Knickerbocker Trucks, and the Protected Cooler of the Universal Vehicles Under the Driver's Seat.

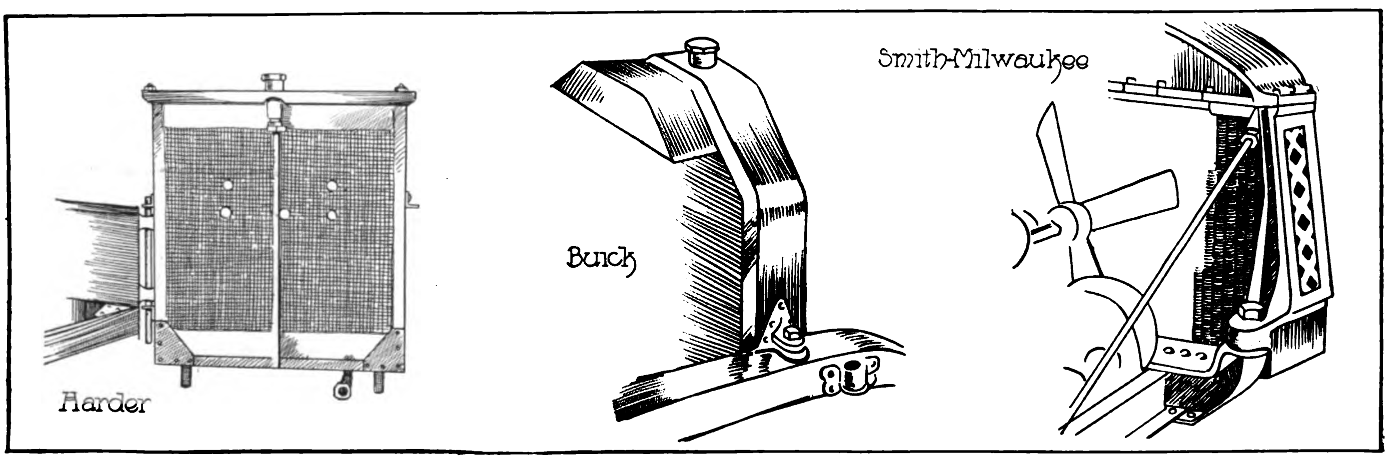
of a segment of the eccentric, which may be secured in any desired graduation by a bolt. This is independent of the adjustment that may be made at the axle end of the rod.

The radius rod of the Hercules delivery wagon is constructed so that while the rear end oscillates on the rear axle it carries the brakes, both external contracting and internal expanding, and the forward end is pivoted at the jackshaft hanger clamp. The adjustment is made by a bolt that is secured by clamping. Provision is made with the Adams and Lauth-Juergens machines to stiffen the chassis frames where the jackshaft hangers are installed by unusually long plates, in both cases the fittings extending backward from the hangers, affording very secure anchorage. One of the features of the Vulcan trucks is the bolted-on sprockets, which can be removed from the end flange of the shafts by loosening six bolts. This method is regarded as more economical than keying.

The necessity of protecting radiators, and making possible quick repair has been worked out well in the large Reo delivery wagon, in which there are 24 sections, these being held at top and bottom by yoke clamps that each retain two ends. These sections have three tubes each. It is possible to remove a section and by plugging the four holes by which it is connected for the circulation of the water with the base and header, to continue to use the machine. In fact, a number of the sections may be removed and the efficiency of the radiation will be such the machine can be operated. Several of these sections can be kept in reserve and the vehicle need never be out of service from a radiator leak or damage.

The Croce radiator is typical boiler construction, the horizontal tubes being of large size and expanded in the front and back of the cooler. In the event of a leak or damage the tubes may be plugged temporarily, or expanded to make a tight joint. The radiator of the KisselKar 2500-pound delivery wagon is a finned tube type, the tubes being mounted in an aluminum frame that is seemingly massive and is bored to reduce weight, while it is heavily ribbed to secure radiation. This radiator is mounted in enclosed spiral springs carried on the frame side members.

The radiators of the Universal machines of the motor under the floor type are located at the back of the seat and beneath it, being protected by the seat frame and a grating against damage from movement of the load or while handling the freight, and these have a flat top with a header carrying a large filling spout. The radiator is mounted on supports located on the frame side members. The Buick radiator, of the flat tube type, has an enlarged or auxiliary header that overhangs the motor and this gives a considerably increased water capacity with the same radiation area. The Smith-Milwaukee truck radiators are with the header and base of considerable capacity and the finned radiating tubes are set into these with rubber



The Provision Made with Harder Trucks for Accessibility, the Auxiliary Header or Tank of the Buick Delivery Wagon, and the Sectional Skeleton Radiator Frame of the Smith-Milwaukee Vehicles.

gaskets. In the event of leak or damage any number of these may be removed and other tubes installed with comparatively little labor. The headers and bases are assembled with skeleton side members to assist radiation. The radiators of the Harder, Ideal and Knickerbocker machines are constructed to swing, so that by loosening the water manifold connections and removing the bolts retaining the supporting brackets at the right side with the Harder and the Knickerbocker vehicles, and the left side with the Ideal, the radiators may be swung as doors and access may be had to the motors or to the coolers for necessary work.

MARTIN TRACTOR IN HEAVY WORK.

Hauls 19 Tons of Stone at Eight Miles an Hour in San Francisco Traffic.

The possibilities of handling heavy freight by the use of motor vehicles are being demonstrated daily at San Francisco, Cal. M. Lennegan & Son's Knox-Martin tractor recently hauled 19 tons from pier 25, Lombard street, to Howard and Seventh streets in a very few minutes. To have transported the same amount of stone over the distance by horses would have easily consumed half a day.

On the low-bed truck attached to the tractor was one piece of granite weighing 11.5 tons. Behind the tractor was attached another stone wagon as a trailer, and on this was a piece of stone weighing over eight tons. The machine was able to draw the load easily at eight miles an hour in the open traffic.

MOTOR FUEL INVESTIGATION.

Research for Substitutes for Gasoline to Be Made Under S. A. E. Supervision.

A committee appointed by the National Association of Automobile Manufacturers to investigate the possibilities of satisfactory substitutes for gasoline for fuel has arranged with the Society of Automobile Engineers for the technical tests and general research to be conducted by that body, while the association will possibly determine such matters as are of a purely commercial character. The association committee considered in a general way the aspect of the petroleum industry, the source of supply available, probable oil fields unexploited, transportation and storage facilities, refining cost and other elements of material importance.

It was considered best to have the scientific research made by the society and to have this include fuels that are available and differing carbureting instruments, and it is probable that inventors and others interested will be given opportunity to demonstrate hydrocarbons and the possibilities with reference to manufacture. Of course cost will be a material factor. The research work to be done will cover so far as may be necessary the work of the association's committee, and besides the investigation of the fuels practically the same attention will be given to tests of carburetors. In addition the investigators will endeavor to learn what changes in present carburetion methods will increase the efficiency of and satisfaction with low grade gasoline.

It is stated that the different oil producers and allied interests are willing to co-operate with the society in the work. It is pointed out that the fuel supply of the future is an intensely important subject, so that it will be necessary to determine so far as possible the hydrocarbon that will be most economical and the most practical method of utilizing it. The policy of the society in the investigation will be, with reference to carburetors, to determine what physical and chemical proportions are most desirable in a fuel and the best means of applying them, as well as to establish definite relations between the necessary velocities, volumes and temperatures.

FOREIGN MARKET DEVELOPMENT.

Secretary of Commerce Redfield Proposes Means for Trade Exploitation.

Secretary of Commerce Redfield makes the definite recommendation that it is necessary in the study of the activities of the manufacturing nations of the world to add to the consular service and other channels of investigation now available, by the creation of a division of the bureau of foreign and domestic commerce that will have funds and attaches desirable to give the fullest information on all subjects beneficial to the business life of the nation.

He proposes that there should be a corps of commercial attaches accredited to the principal states of Europe by the Department of State, yet under the guidance of the Department of Commerce, whose members would have the same purpose in commercial and industrial life that the military and naval attaches stationed abroad now have. He suggests that such a corps could make general investigation to amplify the local reports of the consuls, and direct attention toward every activity that justified. He believes that the return would be in every way beneficial and while he is of the opinion that the appropriation necessary to insure such service need not be large, it would have to be sufficient to secure the class of men who could obtain and prepare the information.

An Alco truck, owned by John Lucas & Co., Philadelphia, Penn., loaded with three tons of paint, was driven from Philadelphia to Pittsburg, a distance of about 400 miles, in five days, the start being made March 17. The night stops were made at Lancaster, Gettysburg, Bedford and Greensburg. This was the first overland delivery made between the two points in 25 years, when horses made the journey in several weeks. The machine is now in use at the Pittsburg branch of the owner.

INDUSTRY RAPIDLY RECOVERS FROM DISASTER.

AS A result of the recent flooded conditions in Ohio and Indiana, hundreds of lives were lost, thousands were made homeless and property totalling millions of dollars was destroyed. For a time it was feared that the automobile industry and lines closely allied therewith had been seriously affected. Reports from the stricken district immediately after the work of re-establishing communication was begun would seem to indicate that such concerns were particularly fortunate.

Several companies engaged in the production of motor trucks are located in the area visited by the floods. The cities most seriously affected were Dayton and Troy, O., and that portion of Indianapolis, Ind., known as West Indianapolis. A number of other cities and towns in this district were inundated, and the whole section suffered more or less through the destruction of bridges, highways and railroad lines. It seems probable, however, in the light of recent reports, that the highways themselves are not in as bad condition as was at first supposed, although of course, traffic cannot be resumed under anything like normal conditions until provision has been made for replacing the bridges washed away.

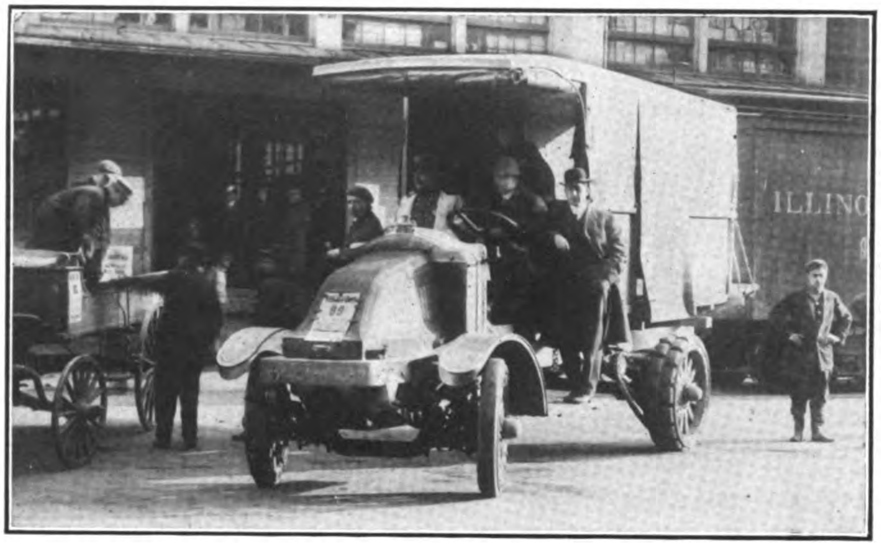
In Dayton, the concerns to suffer directly from the flood were the Dayton Motor Car Company, Dayton Engineering Laboratories Company and the Apple Electric Company. The first is a subsidiary of the Maxwell Motor Company and formerly was engaged in the production of Stoddard-Dayton cars. The two others make starting and lighting systems. The first floors of these buildings were filled with water, but it is stated that practically no damage resulted to stock, much of the space being devoted to offices. The Speedwell Motor Car Company, maker of Speedwell cars and trucks, is located on high ground and the water came no nearer than two squares.

Troy also was in the heart of the flooded district in Ohio. The Troy Wagon Works Company, which produces wagons used as trailers for motor truck installations, reports that the damage to its factory proper was very considerable, but prompt and energetic measures soon restored conditions to normal. The office was badly flooded, damaging records and hampering work temporarily. The Troy Carriage Sun Shade Company, maker of windshields, also suffered from water and did not expect to be able to resume operations before April 7.

The Indianapolis factories partially submerged were those of the Marmon, Marion and Pathfinder, and the body works of R. J. Irvin & Co. The second story of the Marion plant was utilized as a haven of refuge for many people who were caught in their homes when the levee on White river gave away. All these concerns report that the finished stock was out of harm's way and that they do not expect to be delayed materially in filling orders. The Waverley Company, maker of Waverley electric trucks, is located on high ground and reports that it will be able to make shipments as soon as the railroads are ready to take them.

The Ideal Auto Company, Fort Wayne, Ind., maker of Ideal commercial cars, says that its factory was under four feet of water for 10 days, but the direct loss in materials is not nearly so great as was anticipated. The company fears its main loss will come through the fact that it had been doing a good business and had many prospects in towns which suffered much more than Fort Wayne.

At Anderson, Ind., the electric light and water plants were forced to close down, and Lambert farm tractors, made by the Buckeye Manufacturing Company, were impressed into service to supply the necessary power to pump water from several of the quasi-public service institutions. The truck plants of the Buckeye company and the Nyberg Automobile Works were not damaged.



One of the Six Kelly Trucks Taking on a Load of Supplies for the Flood Refugees in Dayton, O.

The Kelly-Springfield Motor Truck Company, Springfield, O., reported that its plant was in no way disturbed by water, but the fear was expressed that the receipt of material and the shipment of completed vehicles might be delayed somewhat.

Water came very close to the plant of the Willys-Overland Company, Toledo, O., maker of Overland delivery cars, but did not enter the building. So far as can be learned the industry in Toledo did not suffer materially.

At one time it was feared that the tire concerns in Akron, O., were heavy losers, but it transpires that but one building was reached by the water, this being

the engine room of the Goodyear Tire & Rubber Company, maker of Goodyear tires. The fires were put out, but the damage was very slight.

At Youngstown, O., the Republic Rubber Company, maker of Republic tires, placed its private water supply at the service of the city when the municipal pumping station was flooded. By so doing, it undoubtedly aided in reducing loss by fire. The second morning of the flood fire did some $75,000 damage in the business district, and without the tire company's water supply it probably would have communicated to other buildings.

The Rutenber Motor Company, Marion, Ind., reports its Marion plant safe, but the foundry at Logansport, Ind., is said to have been flooded to an average depth of two feet. The shipment of Rutenber motors will not be delayed, however.

While the water did not reach the plant of the Ross Gear and Tool Company, Lafayette, Ind., it was shut down for a week. Edward A. Ross, secretary of the company, believes that the result to the industry will not be serious and he expects that more trucks will be bought than would have been because of the large amount of work that must be done over the flooded district.

Ideal Truck Utilized to Pump Out Flooded Cellars in Its Home Town of Fort Wayne, Ind.

So far as has been learned this practically comprises the list of companies affiliated with the motor truck industry which were seriously affected. Several other motor car and accessory manufacturers have reported no damage. The chief concern is with the railroad situation. With all schedules temporarily abandoned, the problem of receiving material and shipping completed products is very unsatisfactory. However, the railroads already have begun work of restoration, and there seems little doubt that previous schedules will be resumed as nearly as possible within a short time.

Many of the local dealers and distributors have lost much more heavily than the manufacturers. In Dayton the retail salesrooms were located on Third street, in the business centre, which suffered most of all. Not only were the buildings demolished, but show cars, office records, etc., were entirely destroyed. The situation in this respect in other cities was not so bad, however.

In the work of rescue and in the matter of distributing supplies and aid to the rescued, motor trucks and automobiles played a decidedly prominent part. Many manufacturers sent several vehicles to Dayton, among which may be mentioned the six Kelly trucks from the Kelly-Springfield Motor Truck Company, Springfield, O., and the eight Packards from the Packard Motor Car Company, Detroit. In Indianapolis several White trucks, made by the White company, Cleveland, O., did splendid work. Had it not been for these vehicles, in many instances it would have been impossible to transport food and supplies, since the railroads were unable to reach the needy ones and horses were wholly incapable of coping with the flooded conditions.

The same situation prevailed, in a measure, in connection with the tornado at Omaha, which preceded the floods of Ohio and Indiana by only a few days. Over 200 people were killed, many hundreds injured, thousands left homeless and property valued at between $5,000,000 and $10,000,000 destroyed as a result of this storm. Motor vehicles responded promptly, carrying the injured to hospitals, transporting soldiers, firemen, police, surgeons and nurses to the afflicted district, and distributing food and supplies.

In each instance the thorough practicability and dependability of the automobile, whether designed for business or pleasure, was ably demonstrated. And particularly as a result of the floods, it may be forecasted that there will be a decided market for the mechanical transport in all lines of activity in the districts affected. The industry is fortunate in escaping with so little damage, although in this connection it should be remembered that thousands of men employed by the industry lost all their household effects, and in some instances there was deplorable loss of life as well.

Since the above was written, additional information has been received from the Brown Commercial Car Company, Peru, Ind., maker of Brown vehicles, in which it is stated that the water in this factory averaged about two feet. Vice President C. A. Wallerich writes that the goods damaged were of a character which could be replaced easily and that the concern will not be hampered. The chief delay was occasioned by the fact that most of the workmen lost all their personal effects.

The Crescent Motor Truck Company, Middletown, O., writes that the flood did not reach its factory.

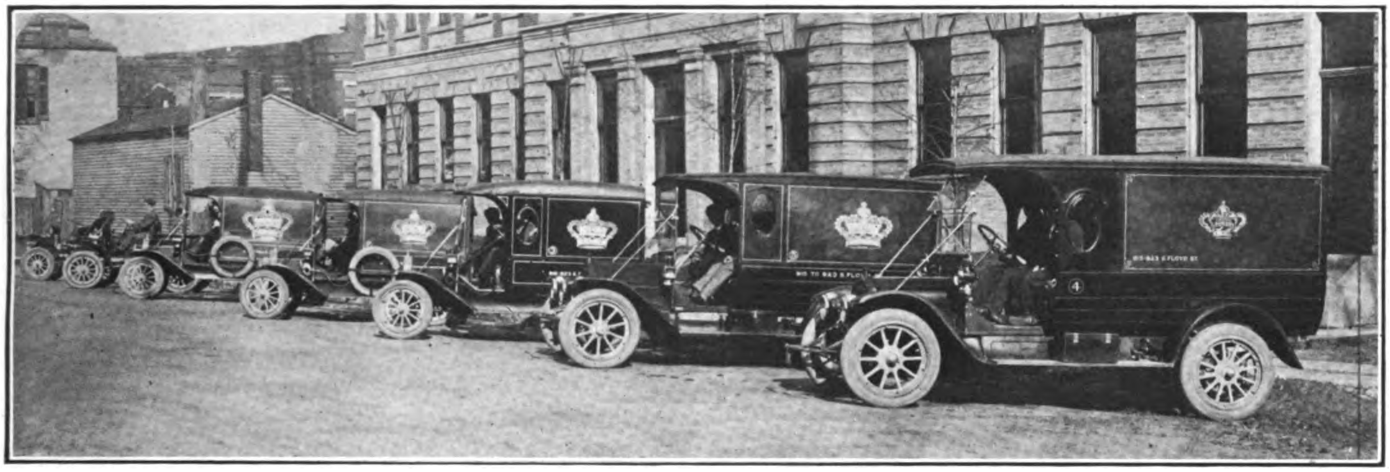
MOTOR WAGON ECONOMY IN LAUNDRY WORK.

Only Exclusive Motorized Service of America, at Louisville, Ky., Affords Business Development of Surprising Proportions and Yields Great Economy.

By G. D. Crain, Jr.

THE Crown Laundry Company has for a number of years been regarded as one of the most progressive business enterprises of Louisville, Ky., and while it is known to the people of that city as being one of the few concerns in it using motor vehicles, it is hardly probable that even the best informed authorities of the power wagon or laundry industries know that it is the only firm of the kind in the United States, and probably in the world, using a complete motorized equipment.

The business has been developed consistently and Manager W. A. Haas has created a reputation that is justified by the building occupied, the equipment and the character of the work as being high class. It was not need of prestige that prompted Mr. Haas to make experiment with motor vehicles in the collection and delivery of his work, and it was a realization of the possibilities of economy that impelled him to change from animals to power delivery wagons after he had given the machines a thorough trial.



The Delivery Equipment of the Crown Laundry Company, Louisville, Ky., the Only Concern of the Kind in America That Has Installed a Completely Motorized Service.

The experience of Mr. Haas is unusually interesting in that it in every way controverts the very generally accepted belief that motor wagons are not economical in work where the stops are frequent and the routes are sometimes short. He has now six machines in use and utilizes them to admirable advantage. His business does not differ from any other of the same character and he has not revolutionized methods, but he has found it possible to obtain results by careful study of the possibilities and adapting the service to the conditions.

Had Mr. Haas been willing to accept the assumption of those who believe the horse is the cheaper for work where the routes are within a city, and where the stops are generally frequent, he would not have felt willing to abandon the animals and made the investment necessary for the change. Having found what he could accomplish with one machine, after working it for a sufficient length of time to justify an opinion, he decided to motorize his transportation and did so.

In the work of horses the usual limitations of animals were experienced, these being principally a diminished capacity in the periods of the year when there are extremes of temperature, a necessity of having a reserve to provide for ordinary emergencies, the lack of elasticity of service in the event of need and the constantly increasing expense of maintenance. In addition, the demands for serving the customers in all parts of a city of extensive area and the constant increase of the business meant the purchase of more equipment. The question was whether or not it would be best to continue to utilize horses or learn what could be done with motor vehicles. Mr. Haas decided he would try out the automobile.

The first vehicle purchased was a single-cylinder Cadillac pleasure car. The chassis was stripped and it was converted to a light wagon by the installation of an open express body. The machine was utilized for what is known as a "pick up," and made the round of the agencies, collecting and returning baskets, covering a good deal of the city each day. This made possible bringing to the laundry each day washings that would not have been received until later, and with the earlier collection the work was considerably expedited. When this machine was installed eight wagons were used.

For the purpose of demonstrating the actual cost of the horse service it may be well to show the cost for a year of maintaining it, and 1910, before a machine was

placed at work, will sufficiently show the expense:

Investment.

Eight wagons at $200 each	$1600.00
Eight horses at $175 each	1400.00
Eight sets of harness at $30 each	240.00
Total	$3240.00

Operation.

Stable help at $50 a month	$600.00
Feed	1219.00
Wagon repairs	212.00
Harness repairs	71.80
Shoeing	312.90
Total	$2415.70
Wages, drivers, helpers, etc.	5760.00
Total	$8175.70
Interest on investment at 6 per cent	194.40
Total	$8370.10

The driver of each wagon had charge of the delivery and was paid $60 a month, and on some of the more congested routes "jumper" boys assisted them. Each driver handled his own route and in cases of special work and the like the delivery was sometimes taken care of by an emergency trip. Generally each driver had practically all he could do, the first part of the week, as with all laundries, being given over to collections and the latter part to deliveries.

Daily Report of Drivers, Printed in Black on White Paper, Three Inches Length and 5.5 Inches Width, Padded.

The work with the Cadillac "one-lunger" was so satisfactory that three Ford light delivery wagons were bought, and then came a White 1500-pound delivery wagon and a Cadillac delivery wagon of approxlimately the same capacity. As the machines were bought the horses and wagons were disposed of and then the stable was converted into a garage. This building is of brick and contained 10 box stalls. The floor was cleared and a cement flooring that may be flushed was laid, this having good drainage that it may be kept clean, and a gasoline storage outfit was installed with the pump in a separate structure about 50 feet from the garage building. The garage was piped for a supply of compressed air, served from a compressor in the laundry. The garage, 25 by 50 feet, is located at the rear of the laundry plant, and convenient to it, reached by an alley, is a loading platform. This arrangement, which was planned when the laundry buildings were erected, eliminates the possibility of such interruption of the work as might be experienced were the loading platform in the street.

The work done with the six motor wagons is ordinarily equal to what would be accomplished with 12 wagons, but this does not represent the greater radius of movement possible, the elasticity to the service in the event of need, nor the possibility of meeting the natural increase of the business without additional equipment. The cost of the motor wagons was $6980, the first Cadillac being $700, the first Ford $900, the second and third Fords $640 each, the White $2600 and the second Cadillac $1500.

To equal the work of the motor vehicles it would be necessary to have 12 animal wagons, which would cost, taking the figures of 1910 as a basis, the following:

Investment.

12 wagons at $200 each	$2,400.00
12 horses at $175 each	2,100.00
12 sets of harness at $30 each	360.00
Total	$4,860.00

Operation.

Stable help	$900.00
Feed	1,829.04
Wagon repairs	342.00
Harness repairs	107.60
Shoeing	469.32
Total	$3,647.96
Wages, drivers, helpers	8,640.00
Total	$12,287.96
Interest on investment at 6 per cent	291.00
Total	$12,578.96

The records of the company are very accurately kept so far as the expense of operation is concerned, and while the price for gasoline will be somewhat increased as compared with the cost for last year, on the basis of the work for 1912, which is under consideration, the machines have made a remarkable showing. This is applied to actual results in dollars and cents, and does not comprehend any of the advantages that are obvious to the reader. The statement for the year specified shows the following:

Investment.

One Cadillac wagon at $700	$700.00
One Ford wagon at $900	900.00
Two Ford wagons at $640	1280.00
One White wagon at $2600	2600.00
One Cadillac wagon at $1500	1500.00
Total	$6980.00

Operation.

Miscellaneous repairs	$887.54
Tires	704.41
Gasoline at 15 cents a gallon	700.00
Oil at 40 cents a gallon	73.41
Total	$2365.36
Wages, drivers, helpers, etc.	5280.00
Total	$7645.36
Interest on investment at 6 per cent	418.80
Total	$8064.16

It will be seen that the cost of operating the six motor vehicles was $305.94 less than the expense for the eight wagons, and these are actual figures. Taking the horse equipment that would do the work of the six machines it will be seen that there is a difference of $4514.80 between the cost of the machines for 1912 and

the expense determined by an average of the cost a wagon for 1910.

It will be noted there has been no depreciation charged against either animal or automobile equipment, but taking both on the basis of 20 per cent., which is the general allowance, this amounts to $1396 for the latter and $972 for the former, or a difference of $524 to be charged against the motor equipment. There is a balance of $4574.80 in favor of the motors, and deducting the difference in a depreciation charge there is still $3990.80 to be credited to the motorized delivery. As a matter of fact the actual ratio of depreciation may be regarded as problematical, for the machines are excellently kept and ought to give a very satisfactory service for the period given, but under any circumstances there is a sufficient margin to justify the allowance of even 25 per cent. to be certain of being within the figure. The repair cost is minimum, for the work on the machines is done by mechanics employed at the laundry and no record has been kept of the labor performed by them. This is regarded as a part of the work incidental to the upkeep of the establishment. The labor cost, however, it is stated by Manager Haas, will amount to a comparatively small sum.

The installation of the motor service made it possible to provide for patronage from all parts of the city. It has been used for more than a year and during that time the development of the business has been material. The drivers of the four light machines collect and deliver and have the help of "jumper boys," but the White and large Cadillac machines each have drivers. The work done with each machine is represented by the record for each route, but this is provided for in the regular accounting, and aside from the pay roll the other detail is included in the blank filled by the driver. This states the total distance driven in miles, the gasoline used, the oil consumed, the punctures or blow-outs, if any, and the number of the casing, the number of the casing used for replacement, the speedometer readings and remarks. This is dated and signed by the driver.

Care is taken to maintain a complete record of each tire. A sheet is devoted to each shoe, giving the make of vehicle, its number, the size of the casing, the make, the number of the maker, the date bought and the price. Note can be made of eight installations and removals, the odometer record for each period of service, the period mileage, the total mileage, the replacement allowance (if any), the initial cost, the service cost, the repair cost and the total service cost. The quantity of fuel consumed will be about 4700 gallons a year, and on the basis of experience 200 gallons of oil will be a very liberal supply.

It is not possible to accurately determine the consumption of fuel or lubricant by average, for, to illustrate, in January, 1913, one Ford on a suburban route was driven 9.9 miles to the gallon of gasoline and 147 miles to the gallon of oil, while a similar machine in general delivery, making shorter runs, was driven but seven miles to the gallon of gasoline and yet made 237 miles to the gallon of oil. During this same period the White machine was driven 6.5 miles to the gallon of fuel and 336 miles to the gallon of oil, and the larger Cadillac for seven months averaged seven miles to the gallon of gasoline and 168 miles to the gallon of lubricant. The old Cadillac made 7.6 miles to the gallon of fuel and 86 miles to the gallon of oil. The White machine, however, being the largest and heaviest of the equipment, does the hardest work, and it is in some classes of service rated as being equal to six horses and wagons.

Relative to tires, different makes have been tried to determine what will give the best service, and during one period 36 casings were driven 87,839 miles, or an average of 2440 miles each, at a total cost of $726.70, an average cost of $20.18. These cost figures are based upon the replacement allowance when the shoes did not yield the guaranteed mileage.

Besides the economy of the service a substantial value can be placed upon the use of the vehicles, and this is of material importance when the development of the business is considered. Prompt service is another potent factor that cannot be underestimated.

REMARKS:

Tire Record, Printed in Black on White Paper, 7.5 Inches Length and 8.25 Inches Width, Padded. These Records Are Kept for Each Casing.

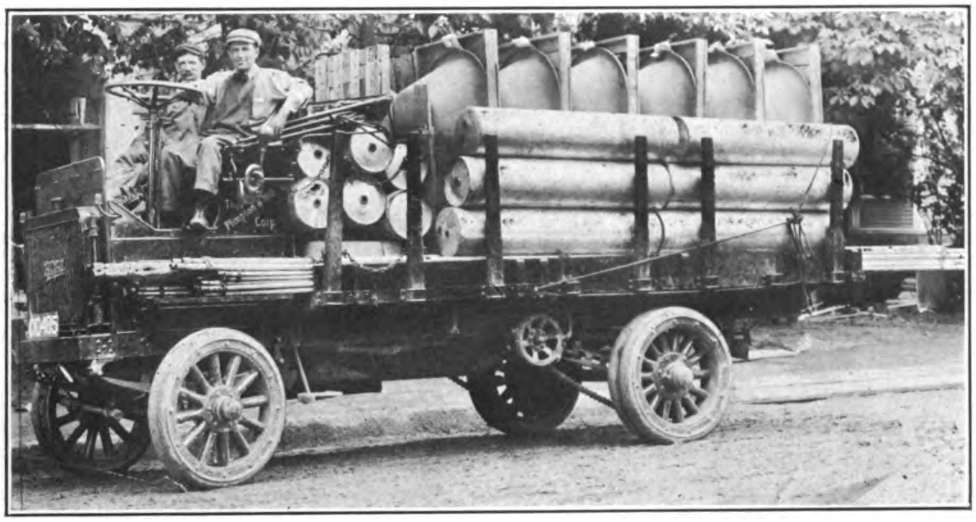
In building a section of the local sewerage system the Prendergast Construction Company of St. Louis has used a two-ton Dorris truck, made by the Dorris Motor Car Company of that city. All the material for the cement work, etc., has been hauled with this vehicle, which in addition to carrying its rated load has towed a big dump wagon carrying 7500 pounds and utilized as a trailer.

The Avery Company, Peoria, Ill., will build this year three sizes of tractors, 12-15, 20-35 and 40-85 horsepower ratings. The smallest and largest machines are new and the other was produced last year.

TRUCK ECONOMY IN CITY DELIVERY.

THE experience of the firm that utilizes a single motor vehicle in connection with animal service, and develops methods of use that satisfactorily economize, is always interesting. The cost of operation of one machine is relatively more expensive than several and usually the lack of facilities that would be possible or practical with the larger installation limits the productiveness that might be realized.

The Plimpton & Hills Corporation, Hartford, Conn., placed in service in May, 1912, a three-ton Pope-Hartford truck with a view of experimenting it in comparative work with horses, and used it in all forms of transportation. The company deals in plumbing and steam fitting supplies at wholesale and its customers are scattered throughout the city and its suburbs. With the increase of business and the demands of patrons for expeditious delivery horses were found to be hardly adequate and an investigation of the cost showed a surprising expense. It was estimated a truck would be the equal of five horses and on this basis an analysis showed that the expense for animals was larger than was believed.



The Pope-Hartford Three-Ton Truck Used by the Plimpton & Hills Corporation, Hartford, Conn., with Body Fitted for Carrying Plumbing Supplies.

The feed bill of the concern for a year was $1825, to say nothing of other cost that brought the expense up to a figure that was thought excessive. Good care was given the animals, they being under the supervision of a member of the firm. The belief was that the expenditure would increase rather than decrease and it was decided to buy a truck. Having determined what machine would probably serve the best and selecting that of local make because of the business relations with the maker as well as the possibility of obtaining service when required, the company determined to maintain its own business policy with reference to the vehicle.

The usual practise is to depreciate a truck at the rate of 20 per cent. a year, this giving a valuation of 80, 60, 40 and 20 at the expiration of the fourth period, this showing the loss of the entire price at the end of five years, but the company has accepted it as a part of the equipment of the business and not a separate item of expense. For this reason 50 per cent. is charged off to depreciation the first year, and each subsequent year 50 per cent. of the previous year's valuation is subtracted, which gives a reduction of 50, 75, 87.50, 93.25 and 96.63 from the original price, leaving a valuation of 3.37 per cent. at the end of the period. While it is estimated that the truck will last about five years, and while the result does not materially differ so far as the actual depreciation is concerned, it does materially reduce the valuation of the actual investment in the machine the last three years of its use, and, if it is well maintained, as undoubtedly it will be, it is probable that there will be a greater economy than would be shown in the statement as given. It will also be noted that while the policy brings the cost of operation high the first year, it decidedly reduces it each following year. Interest on the investment is also charged to the firm's equipment rather than to the truck specifically. The members of the company state that it is believed that at the end of five years trucks will be so improved that even with a high standard of maintenance it will be well to make a change.

The work for the truck is transporting heavy and bulky material, something like 20 tons being handled each day. The loads are made up of bath tubs, iron sinks, steam and hot water boilers, radiators, tanks, furnaces, pipe, fittings, etc., and stock that is frequently of considerable weight. The custom is to make up a load and send the machine so that there will be but little unproductive mileage, although in some instances loads are sent to a single customer. The orders are often delivered to the places where work is progressing, and at the prevailing rates for plumbers' and steam fitters' wages a prompt delivery promotes patronage.

The average daily mileage is 35, and in the time the machine has been in service it has been driven about 11,500 miles. During this period it has not been withdrawn for repairs. The work has been practically within the city, for hauls beyond the city's boundaries are discouraged. The firm still has several horses in use, but it is purposed to dispose of these and install another machine. The change will perhaps be made this spring.

The cost of operation for the first year, which includes the depreciation charge of 50 per cent., is computed at $11.96 a day, and it is maintained that the

truck will do the work of at least five horses, so that it will be seen that the economy is considerable from this point alone. The intention is to keep the machine on the road so far as this can be done, which the mileage will demonstrate, and the driver, who has a factory training and understands trucks thoroughly, has a helper. Both men handle the freight and in this manner the loading and unloading time is minimized. The driver gives the truck whatever attention is necessary, and he is expected to keep it in operative condition. The company believes that it is well to have a thoroughly competent man in charge of the machine and have him responsible for its operation.

The truck is equipped with a body especially adapted for the work, there being racks on either side for carrying pipe, which equalize the load and lessen the length that would be necessary were loading space wholly behind the driver's seat. The truck is kept in a garage built at the plant in Jewell street. During the past winter, as the temperature has been seldom very low, a somewhat unusual custom has been followed. When the machine is brought to the garage at night the water is drawn from the radiator and the motor and before starting in the morning the cooling system is filled with hot water. This insures against freezing and at the same time makes starting comparatively easy.

WANT TRUCKS BUILT IN NEW YORK.

Merchants' Association Urges Advantages of Metropolis for Vehicle Building.

The Merchants' Association of New York at its last meeting listened to discussion as to the advantages of New York for motor vehicle manufacture as compared with other cities of the nation, comparison being made particularly with Detroit. The industrial bureau of the association, of which Henry Morganthau is chairman, has sent a circular statement to those engaged in the industry in which is set forth at length the reasons why New York is, as the commercial centre of the nation, a better location than western cities, from the viewpoint of the committee.

The labor, housing, local transportation, the shipping facilities, banking and other conditions were compared, and it was maintained that with reference to factory locations, proximity of raw materials, highly skilled labor, liberal banking policies and with a market of unequalled proportions, New York had many advantages that should appeal to the business man. It is held that a third of the population of the country, and a market that is greater in proportion to inhabitants than in any other section, is within 400 miles of New York, and as it is believed necessary by every manufacturer to locate an office, and a service station if the business transacted is of material proportions, in the metropolis, it would be good business judgment to have the manufactories where they could give the highest character of service. It was pointed out that with the cost of railroad transportation increasing it would be logical for the manufacturers to have assembling plants in New York and send the parts there for the construction.

It was estimated that from 50 to 65 per cent. of the service wagons used in the United States are in use within 100 miles of New York, and with the improvement of traffic conditions in New York, which is to be expected within a very short time, the demand for these vehicles will greatly increase. So far as exportations are concerned, it is believed that it will be cheaper from every point of view to ship from New York, and shipment may be made for the Pacific Coast cheaper when the Panama canal is completed than by railroad. The completion of the New York barge canal will also cheapen the cost of transportation of raw materials.

SUMMER MEETING OF THE S. A. E.

British Engineers to Be Guests of American Organization in May and June.

Much interest attaches to the summer meeting of the Society of Automobile Engineers, which will take place on the steamer City of Detroit III during a voyage from Detroit to Sault Ste. Marie and return June 4-7. In connection with the meeting will be the formal entertainment of members of the Institution of Automobile Engineers and the Society of Motor Manufacturers and Traders of England, who will be present as guests of the society, and who will participate in the presentation and discussion of professional papers. There will be four professional sessions of the society and there will be entertainment, sports and recreation.

The English visitors will arrive in New York about May 26 and will be entertained by the society and the Metropolitan Section until May 28, when departure will be made for Pittsburg, where one day will be passed. May 30 the Speedway motor car races at Indianapolis will be seen and the second day given over to visits to the automobile factories in that city. Detroit will be reached June 1 and the programme calls for visits to several of the automobile factories and differing forms of entertainment, with a banquet at the Pontchartrain the evening of June 3. Returning from the steamer voyage, June 8 and 9 will be passed at Cleveland and June 10 at Buffalo, where the visitors will divide, some to return with the S. A. E. members to New York, and others to make a visit to New England, where they will go through some of the principal factories of Providence, Hartford, New Haven and Bridgeport.

KisselKar on Pacific Coast—The Kissel Motor Car Company, Hartford, Wis., has delivered a 50 horsepower KisselKar police patrol wagon to the city of Stockton, Cal. In test this car was able to develop 46 miles an hour.

ADVERTISING RATES.
Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.
Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.
Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

SYSTEM THE KEYNOTE OF ECONOMY.

The value of system has always been understood. The one great obstacle to its application has been inability to realize possibilities and the unwillingness of many to abandon methods that have been the vogue. The success of many of the great industries has been through the utilization of products that were once considered waste. Others have profited largely through the increase of production without greater expense for producing aside from material. System as applied to transportation means economy in just the same sense. The best examples are not always found in the large enterprises, although these are perfected organizations, for often conditions will not permit the most economic uses. Frequently the deliveries of comparatively small firms are admirably developed, and demonstrate that with even no material change in facilities, but with judiciously conceived methods, a large saving can be made. The reason for this measure of success is a careful study of possibilities and adaptation of use of equipment to realize them to the fullest degree. The man who measures motor vehicle service by accurate knowledge of cost of performing work with differing methods of transportation can economize, but he who bases his judgment on assumed standards is absolutely without facts to guide him.

THE VALUE OF EXPERIENCE.

Those who desire information relative to the possibilities of service from motor vehicles have the option of basing judgment upon their own limited observations and uncertain opportunities for acquiring material facts, or depending upon those who specially investigate and carefully prepare data that will be useful to those in the same lines of transportation. The trained investigator is a specialist who can always reflect the value of a method or system, and when statements are made that demonstrate possibilities through specific application, and are without any other purpose than to emphasize practical results under given conditions, it can be assumed that these can be relied upon.

Experience reflected by those who are competent to judge because of careful investigation of systems and facilities that are regarded as efficient and productive is always worthy of consideration. It is not expected that methods and policies can always be adapted to another service, but the knowledge of how capable business men deal with transportation problems ought to be suggestive of ideas that are or may be made valuable. Generalities and theories are worthless, but practical experience, when it can be obtained with comparatively little effort, can be valued according to the type of man seeking it.

RECORDS OF TRUCK SERVICE.

The owner of a motor truck or wagon who does not keep an absolutely accurate record of the work performed and the time required for it has no knowledge of the practical value of the machine. This does not mean that it is necessary to maintain an expensive system of accounting, but it is imperative to know what service the vehicle is giving, for no other data will inform him whether or not it is being worked extravagantly or economically. The man who places reliance upon the judgment of his driver to work a truck to its greatest value may have sufficient reason for so doing, but it is safe to assume if a man has such capacity there is little need for him to drive a machine.

If men who own motor trucks were to follow the work done by them for a few days and had intimate knowledge of the conditions in which they are used, they would have practical knowledge that would be invaluable to them, and which might be worth a great deal of money. The man who knows the details of his business, who can judge from the reports made him the productiveness and conditions with regard to administration, has his affairs well in hand. Such men seldom relax their command or control. It is imperative that this same degree of careful supervision be exercised with reference to the delivery and haulage. But to undertake to judge without facts is fallacy.

Where large number of machines are in use the record is considered necessary, but exact data are even more imperative with the service of a few wagons because the economies may not be relatively as large. And the wider the experience the greater will be the opportunities for applying methods that will be productive. Exact knowledge is a large asset in business.

TRACTORS A BIG SAVING IN LUMBER TRADE.

Equipment of the George W. Gale Lumber Company, Cambridge, Mass., of Five Electric Machines, Utilizing Wagons as Trailers, Shows Remarkable Economy---For a Period of 189 Days Three Did the Work of 17 Horses Each.

By William W. Scott.

DISTRIBUTION is one of the largest problems with which lumber dealers and manufacturers have to deal. Wherever possible yards and manufactories are located on or near railroads and water fronts, where shipments of stock may be received in large quantities, for lumber is always bulky and heavy, and handling is an item of material expense. Buying is generally on a free-on-board basis, and transportation charges are no inconsiderable part of the cost when received at the yards. As shipments are either by carload or cargo economy has always been considered in yard location, but until the possibilities of motor vehicles were realized but little attention was given to the delivery cost.

The limitations of animal haulage have long been understood and yet there are few concerns that can give even approximate cost of delivery. The custom has been to charge a yard or mill price and to add to this whatever has been decided as a cost sufficient to meet an estimated expense. The business of the average lumber firm varies according to the season of the year, and at times the demands are such as to require perhaps double the number of conveyances. This condition has necessitated either the maintenance of equipment that is not productive during a part of the year, or hiring additional horses and wagons whenever needed at an expense greater than would be realized with those constantly maintained.

Battery-Driven Tractor Built by Owner from Couple-Gear Components to Meet Special Service Needs, Drawing Horse Wagon as Trailer.

This variable character of the business differs according to the local conditions, and it is at times more strongly manifested than at others, but as a rule with horses and wagons or drays when the demands for delivery are the greatest there is, because of numerous considerations, a lessened capacity. This applies especially to hot weather, and when the hauls are long the horses must be favored. Lumber is not easily handled and is sold in greatly varying dimensions. In building operations large quantities are often required, so that for economy it is desirable to carry loads as large as possible

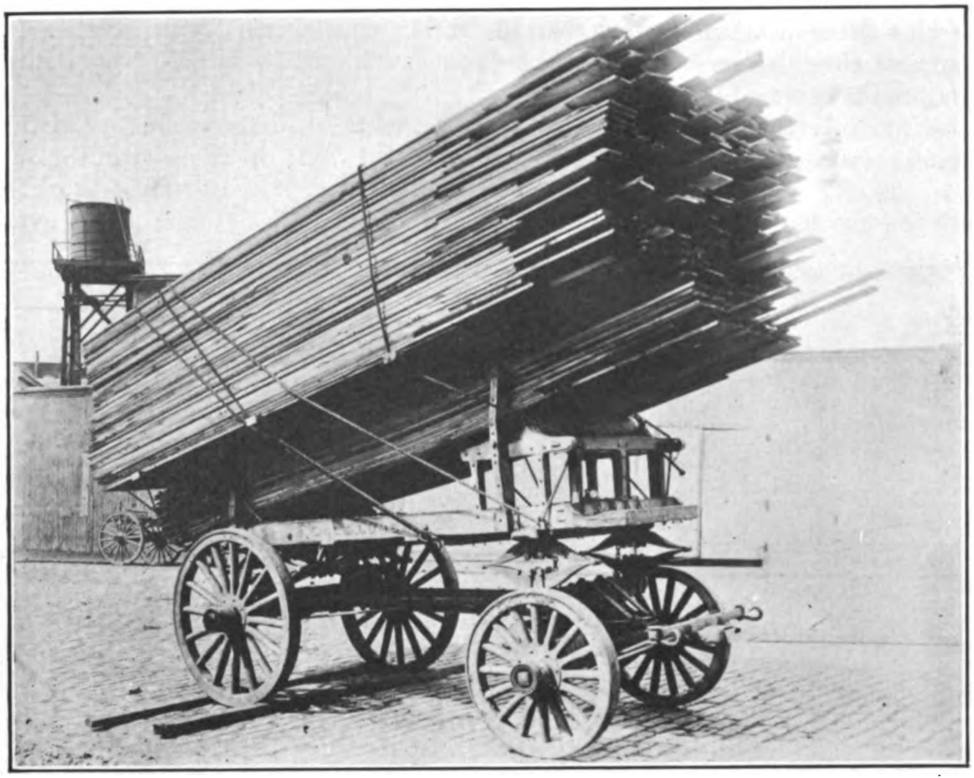
While wood varies greatly in weight it may be practical to average the soft grades at two pounds to the square foot. As it is usually sold by the square foot, an inch in thickness, loads are generally stated on the basis of 1000 feet. Or, to put it another way, board measurement is the rule by which lumber is bought and sold. Under ordinary circumstances yards are devoted to one class of stock, either soft or hard wood, and as some of the heavier grades will run as high as five pounds to the foot it should be understood that the statements in this article will, so far as weights are concerned, refer to the softer and lighter varieties.

The greater part of the haulage of lumber in this country is by horses, and while the capacity of the animals may vary considerably, it is entirely reasonable to give some idea of what may be regarded as average work. For instance, the daily mileage is approximately 15, and a good day's work for a horse is moving 15,000 feet of lumber one mile, or its equivalent, such as hauling 5000 feet three miles. Taking 1000 feet as weighing a ton this equals 15 ton-miles for the day. It should be understood that this is a capacity figure and cannot be attained unless the animal is worked constantly and with careful judgment. There are times during the year when this average will not be reached, and it will seldom be exceeded.

Many lumber firms have for years used with horses extra vehicles of differing types, and the reason has been to economize the cost of yard loading. Some have found that additional wagons can be loaded and left at the platforms or sheds or piles, and by changing the teams when they return to the yards from the

empty to the loaded vehicles the time lost has been not more than from three to five minutes. Where the wagons are unloaded there is always delay unless the equipment is fitted for discharging by gravity. For more than a score of years some lumber companies of large proportions have utilized wagons designed for gravity unloading, these having wooden rolls mounted in the frame to carry the load, the forward roll floating and the rear ratchet retained, and the front roll elevated so as to give an inclination of from 15 to 20 degrees to the load.

These wagons often have such a degree of inclination that in loading it is necessary to elevate the rear wheels on temporary blocking until the load is bound, which is done by rope or chain. Other types have the level platform with a series of floating rollers and a rear roller operated by a crank and retained by a ratchet. These are loaded without blocking and the load is bound by chains. In unloading the inclined type the load is allowed to slide backward until the rear end rests on the ground, when the animals can be driven forward and the other end dropped. With the chain bound loads the lumber is carried backward until the rear end drops to the ground, and then the wagon may be driven off.



Quick Discharging Wagon Loaded with 10,000 Feet of Lumber, Weighing 10 Tons, Drawn from Yard into Street by Horses to Economize Time of Tractor.

It will be understood that the economy of quick loading and unloading is known and has been provided for by concerns with large delivery equipment, and it may be said that such wagons may be procured at an expense of from $350 to $400 each. Of course such equipment can only be used with rough stock and finished work must be handled carefully to prevent breakage and staining.

The load that may be carried on the wagon with the inclined frame may be of greater length than that on a regular platform as it may be extended forward a considerable distance, as much as 10 or perhaps 15 feet beyond the seat of the driver. This is a decided advantage, because it is possible to carry longer stock than with the other type and the driver can see whether or not he can clear obstructions or move in traffic more or less congested. With such wagons timber 40 or even 45 feet has been carried, and with the load very evenly distributed. Very large timber is transported on what is known as reaches, with the load connecting the front and rear wheels. When unloaded the wheels may be brought together and the axles coupled by a metal or wooden reach that may be graduated as to length by moving a pin coupling.

The statements as to the vehicles have been made to demonstrate the use of animal wagons adapted for economizing time, and to show that some of the lumber dealers have utilized these to good advantage. Wagons fitted with the bodies and frames of the inclined type and intended to economize time so far as was possible, were used by the George W. Gale Lumber Company, Cambridge, Mass., a score of years ago, and yet with these it was realized that the cost of delivery was increasing because of the greater expense for drivers, maintenance, overhead, etc., and in that there were limitations to the work that could be performed.

In 1907 Vice President F. D. Sterritt, who is the yard and mill executive, gave attention to motor trucks and for practically two years he studied conditions and the work that might be accomplished with trucks. While it will be admitted that the information at his command was limited, and trucks in use at that time were nothing like the carefully developed machines of today, he was not impressed with the vehicles then available, especially as he desired to continue to use the 20 wagons, all in excellent condition and representing from $7000 to $8000 that would be sacrificed. While he was by no means certain what might be done with trucks for delivery the immediate need was to haul lumber between the dock and the yard, a mile distant. While the larger part of the stock is brought in by railroad cars, cargoes frequently arrive by vessel, and these are hauled as rapidly as possible because of numerous reasons.

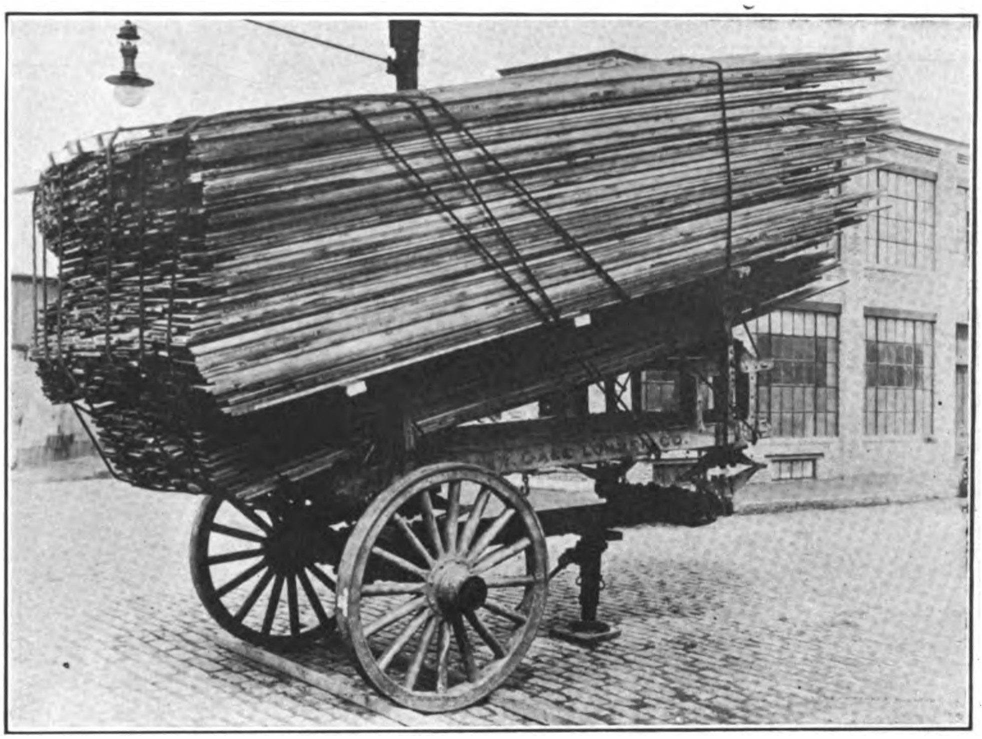
With this form of haulage 50 per cent. is unproductive, and with the limit to capacity and speed of the animals the purpose was to devise transportation that

would carry more or carry loads faster than horses, or perhaps have productiveness in both respects. In the autumn of 1909 a Couple-Gear battery tractor was delivered to the firm, this being the first machine of the kind sold in the vicinity of Boston, and this was the standard type of construction. The wagons owned by the firm are smaller than those used with tractors of this size, which necessitated some changes to adapt the machine to the work it was to do. The battery cradle of the tractor was underslung and side loading and the rear axle was mounted on heavy semi-elliptic springs.

The problem was to adapt the rear end of the tractor so as to make possible the use of the wagons as trailers without impairing their serviceability with horses, and as these were fitted with full elliptic springs at the front and rear it was believed practical to eliminate the tractor's rear springs. Accordingly the chassis frame was shortened to the rear of the battery cradle and the springs removed. A heavy cross frame member was placed at the rear end of the chassis frame and in this was made a round hole about 1.75 inches diameter. A large steel plate was cast with a double web beneath it, forming a channel to take the rear axle, and at the forward end was made a round lug that fitted the hole in the steel frame cross member. The rear end of the plate was extended back of the axle in half-elliptic form, and in the centre was made an 1.25-inch hole. This plate was secured to the axle and the axle was fitted with heavy radius rods extending to the lower rear ends of the battery cradle. The frame of the tractor was stiffened by trusses to the rear axle and on the frame of the chassis was built a box to carry the battery, this being extended both forward and rear, the forward extension forming the seat for the driver, and that at the rear being a tool chest. The brake linkage was not greatly changed at the rear wheels.

When the tractor was completed the body and frame of the chassis ended at a point about 20 inches forward of the rear axle, and the steel plate referred to extended about a foot back of the rear axle. The purpose was to have a support for the turntable or fifth wheel of the horse wagon, and to have sufficient clearance forward of this to permit turns to be made at 60-degree angles without difficulty. When the tractor was converted it was used by loading a horse wagon, jacking the wagon at a point back of the front cross members, backing the tractor so the extension of the plate on the rear axle was beneath the turntable, and lowering the wagon and coupling it to the tractor by a pin that took the place of the king bolt.

Mr. Sterritt was desirous of having a construction that would endure and the change was made under his supervision by the mechanics employed by the company. It was decided to use two batteries to have sufficient power for all requirements, and to charge the batteries a small generator and a gasoline engine was installed. This engine was designed for heavy duty and aside from cleaning and lubricating but little attention was needed. It was considered that this method of generating energy would be more economical than purchasing current from the city mains. At that time the company had in service more than 40 horses which were utilized for delivery, and the tractor was used for hauling the cargoes, and during the spare time between shipments was worked on the long hauls. Its service was begun Dec. 1, 1909.



Wagon with 10-Ton Load Jacked and Front Wheels Removed, Ready for the Tractor to Be Backed Under It and Coupled by Simply Inserting a Pin.

No careful record was kept because the construction work was done under such circumstances that it was not practical to differentiate the labor on it, but the general cost was approximated aside from this item. The machine was garaged in the basement of the mill building and in what was a machine shop, and here was located the charging panel and the engine and generator. This was sufficient for the immediate needs. Because the batteries were carried on the chassis it was necessary to hoist these out and in, which was done by a comparatively inexpensive fitting.

The machine was experimental in the reconstructed form and it was found desirable to make a change or two of minor importance to meet requirements that

had not been foreseen. It gave such economy in whatever work it was used that Mr. Sterritt tested it to what might be regarded as an extreme, on one occasion sending it on a 60-mile trip, carrying both batteries so as to make the distance without stopping for a "boost." In the work of hauling between the dock and the mill the tractor traversed the mile unloaded in from seven to eight minutes, and loaded in an average of 12 minutes, this being at rates of about eight miles light and five miles drawing a trailer carrying from seven to 10 tons. The time required to change the tractor from the light to the loaded trailer at either end of the haul was found to average about four minutes. This change was made by blocking the rear wheels of the trailer and lifting the forward end by the jack, when loaded, or by placing a horse under the reach or perch of the trailer and lifting the turntable with a pinch bar when light.

The installation of the first tractor cost the price of the machine, plus the reconstruction, the gasoline

Gasoline-Electric Tractor and Trailer Carrying 10-Ton Load of Lumber at a Speed of Five Miles an Hour.

engine and generator and such other equipment as was necessary, but the wagons were utilized without change.

The estimate was made by Mr. Sterritt, after careful observation of the work of the tractor under varying conditions, that it was the equal of eight horses, and this without considering the elasticity of its service. The tractor's battery was changed at noon, the battery removed being immediately placed on charge, and when the tractor was garaged for the night the battery it carried was charged without removal. This gave two charges and discharges each alternate working day for one battery, and one charge and discharge each alternate day, thus equalizing the work each had to do. The night charging was done by the watchman, the engine and generator requiring but little attention save lubrication, while it was ordered that the instruction of the battery maker be followed carefully.

The work of the tractor was so satisfactory that Mr. Sterritt decided to secure another, this to be used more in general delivery, and instead of buying the complete machine and reconstructing it, the parts desired were purchased from the maker and with these and those made from the patterns and dimensions used in the rebuilding of the first machine, the second tractor was built. The price of this vehicle was considerably less than the first, and the labor was practically performed by the company's machinist with such assistance as was necessary from men hired for the job. The actual cost of the tractor was somewhat difficult to determine because of the work being incidental to the regular demands upon the mechanic and the labor not always being accurately charged.

The tractor was practically in duplicate of the first and was placed in regular delivery work Nov. 1, 1910. With the use of this machine a garage was built in the yard, a substantial wooden structure with metal interior sheathing and a cement floor, and this was designed to house four vehicles. Because of the additional requirements for electrical current the gasoline engine was replaced by a steam engine and a 20 kilowatt generator, located in the basement of the mill building, and the use of commercial current was discontinued, the company making its own energy for lighting the plant as well as charging the batteries. The steam was generated with the use of sawdust and shavings for fuel, and as the boiler also furnished power for the mill the cost of current was reduced to practically nothing. In fact, aside from the installation of the engine and the generator, and the incidental changes in the wiring necessary there was little expense in the change.

The service of the first machine did not reduce the horses materially, but with the use of the second a number of the animals were disposed of. The work of the tractors was so satisfactory that a third was decided on and this was built in practically the same manner as the second, the parts being purchased of the maker and assembled in the garage of the company. The experience with the first two made the work of construction and the cost less, and in April, 1911, this vehicle was added to the equipment and more horses were sold. Anticipating a probable increase in the machines the garage was added to and a series of four compartments was built, three of which will house a tractor and permit work around it, and the fourth was fitted as a battery room. This has a platform about

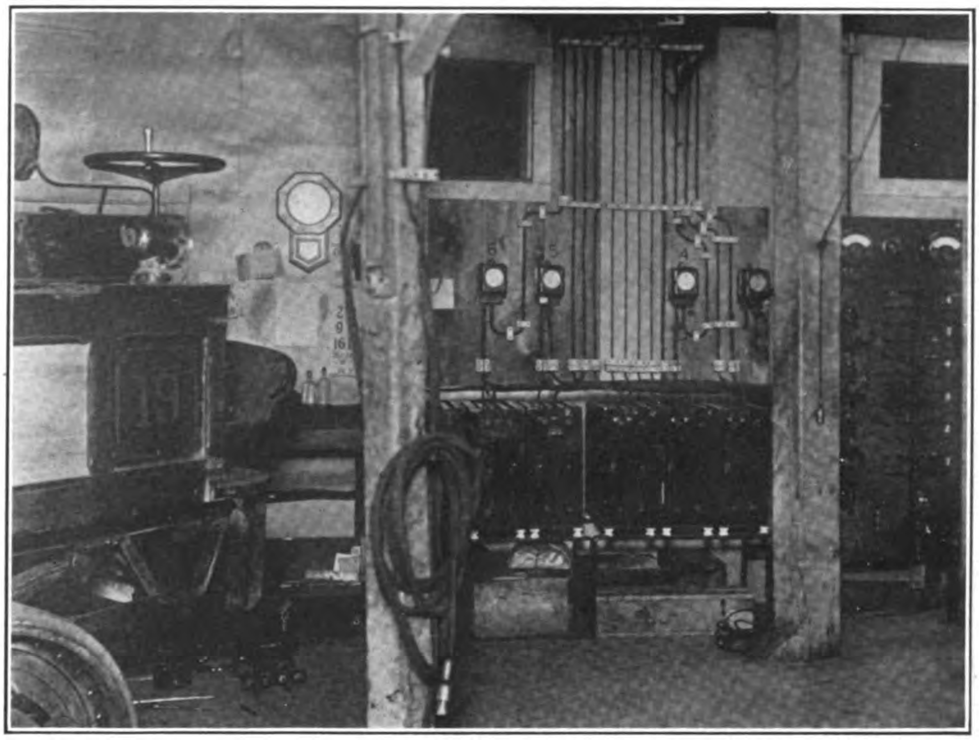
five feet in height at either side the width of a battery, and transversely across the room, about five feet above the platforms, are three steel girders that serve as trolleys and on which three chain hoists may be moved from one end to the other.

Between the platforms is a space sufficient for a tractor to be driven in and along either platform frame is a narrow bridge or shelf on which men may stand and work at the batteries, either on the platforms or in the machine. In the garage is a charging panel equipped for energizing six batteries simultaneously, and this and the six rheostats, installed on a low stand, require but little room. The current is received from the generator, about 100 yards distant. With the two sets of batteries it is possible to charge one from early morning, when the mill is started, until noon if need be, and the other from noon until the power is shut off, with the regular mill force. During the time when the day workers are absent from the mill the watchmen care for the fires and keep the power available. As a matter of fact, if needed, the generator can be operated constantly with practically no attention save lubrication, and the engine is equally simple.

The fourth machine was a gasoline-electric tractor, this being built in the same manner as the others, with parts purchased from the maker and with such modifications as were necessary to utilize the wagons, and it was designed, so far as the body was concerned, so that it might be transformed into a battery vehicle should there be any reason to make the change. With this the power is generated by a gasoline motor coupled to a generator and the motors are supplied with current so long as the engine is in operation. This went into service in May, 1912. Then the fifth machine was bought and as it had been used a short time, when reconstructed it was practically like new.

By the middle of the summer of last year the fifth machine, the second gasoline-electric, had been placed in commission, and at that time the number of horses was reduced to two. This represents the equipment of the company today, the five tractors taking the place of all the animals save the pair used for hauling wagons about the yard and placing the trailers where they can be reached with the least delay. As the mill yard was planned for horse delivery and it has been encroached upon by the increase of the business, so far as is possible the trailers are drawn into the streets, where the tractors are coupled, unless the loads are beyond the capacity of the animals. The horses are also used to haul the trailers into the sheds and to the piles, so that there shall be no delay with the work of the machines.

The five tractors as now used are doing much more than the work of 40 animals. There are seasons of the year when it is necessary for the drivers to work long hours to make delivery, especially when the hauls are long. The assignment of the machines is made by Mr. Sterritt, whose 30 years' experience has given him an intimate knowledge of routes and street conditions. During the spring and summer the drivers of the tractors frequently start working at 3 in the morning, and not infrequently they work as late as 9 in the evening. The orders to be sent out early are generally the longest on the books for the day and before the yard is closed at night at least 10 trailers are loaded and jacked, ready for the next morning. The drivers take the loads as assigned, and by the time they have returned from the second trips more trailers are ready for them, and in this manner the yard force keeps ahead of the trailer loading.



Charging Panel in the Garage of the George W. Gale Company, Equipped for Six Simultaneous Charges—In This Illustration Is Shown Tractor No. 19, Receiving Its First Overhaul After 52 Months' Service.

Each load must be carefully piled and bound and the stock in some instances selected. This work can be done rapidly by experienced men, but it is necessary to have the loads tallied, and so each crew must include a tally man. Were there 20 wagons loading a tallyman must check each load, and there would necessarily be a larger force of yard men. While it is true that the loads vary, this condition would obtain no matter what the form of transportation used, and where the orders are less than a load it is practical to combine several. Combination loads require more time in loading and unloading, but this condition is

one that must be dealt with to the best advantage.

In the hauls where the loads are large the trailers often carry 10 tons, but the average is seven tons. The tractors will move these at a speed of five miles an hour, or double the speed of the average horses, and carrying three times as much. Working overtime the tractors afford an elasticity of service that cannot be equalled with anything else than motorized equipment, and by changing the batteries and charging the spare sets whenever removed from the machines it is possible to keep delivery up to orders under practically all demands. With the gasoline-electric machines the capacity is approximately the same so far as load is concerned, but the radius of movement is unlimited, and the delivery may be made anywhere the customer may desire.

The gasoline-electric tractors are more expensive to operate than the battery machines from the fact that they consume both fuel and lubricant and there is the normal wear of the engine. While they are very enduring because of the heavy construction they are not expected to wear as long as the others, because of the vibration of the engine. When they were built it was with the expectation by Mr. Sterritt that he might eventually convert them to battery tractors, because he believes that there will be eventual improvement of batteries that will justify the change. He does not regard the engine-generator tractor as being as certain equipment as the battery tractor because of the necessary maintenance work that requires withdrawals from service for differing periods.

March 22 of this year tractor No. 19, the first placed in commission, and in its fourth year of service, was placed in the garage for its initial overhaul, and one of the accompanying illustrations, made two days later, shows a part of the machine. The wear shown was so slight that the tractor could have been assembled and might have been run for a considerable length of time, but Mr. Sterritt believed that it would be best to make a thorough job and in several instances holes in castings were bushed and relations accurately restored. Many of the hardened bolts showed practically no evidences of wear and but a very few of these were replaced with new. The cost of the work, aside from the labor, will be very slight. As the power wiring insulation had been attacked by the drainage of electrolyte new cable was installed, but this was the largest single item of expense aside from the labor. Considering that the tractor had been in use about every working day for considerably more than three years, and had been worked overtime sufficiently to make at least 30 extra days a year, this was a remarkable showing. But the machine had been given careful attention and was in no way neglected, despite the fact that it was worked hard.

Battery Room of the Gale Company's Garage, Designed to Afford Quick Exchange of Tractor Batteries, Usually Made at Noon Each Day.

Though there are five machines in the service practically no spares are carried, and the equipment of the garage consists of a few simple hand tools. An extra armature is the only insurance against motor trouble, and a change can be made in a comparatively short time.

Mr. Sterritt does not make a direct statement as to the cost of machines compared with the expense of the horse equipment he used, because of the conditions under which the change was made and that charges were not made of labor, for instance, by his own men, that might not be possible with others. He maintains that the best evidence of the possibilities of electric tractors in the lumber service is that he has completely motorized his yard, and it has the reputation, with lumbermen, at least, of being the best equipped plant in the country. He says that the current really costs nothing because of the wood refuse used for fuel, and that he frequently has inquiries as to his "secret" for generating power so cheaply. To visitors he shows the boiler room when this question is asked.

Mr. Sterritt has a problem that he occasionally propounds to his friends, and it is the result of the work of three tractors, two electric battery and one gasoline-electric, for 189 days, during which time the machines were driven 16,748 miles and carried 9,650,000 feet of lumber that averaged 1.5 pounds to the square foot. He maintains that a horse can transport 15,000 square feet of lumber one mile in a day, and he has asked his friends to determine how many horses would be necessary to accomplish the work of the tractors. The es-

timates volunteered varied from 36 to 1700 horses.

During the period, however, the average mileage was 29.543 daily, and the average load for each tractor was 17,019.40 feet. As the tractors were assumedly loaded half the distance the loaded mileage may be taken as 14.771, and taking the assumed horse capacity of 15,000 feet one mile daily as the base the work approximates what could be done by 16.75957 horses. This work was recently accomplished and it represents practically 27 weeks, or a sufficient length of time to demonstrate that it could be continued indefinitely.

Taking these figures it will be seen that the five tractors equal 85 horses, or at least the three machines for 189 days did work that would require 51 horses to do, and the cost of animals formerly used to the company, the accounting being accurate, was $1.37 each daily. The expense of maintenance of 17 horses would be $23.29, and the cost of the drivers would be at $2.50 daily, $21.25, or a total of $44.54, against which must be charged the cost of operation of a tractor and the pay of its driver, which may be taken as $12.50.

To demonstrate the efficiency of the tractors in another way: With horse equipment the cost of the animals averaged $275 each, a wagon $350 and double harness $50, or $950 for each two-horse outfit. Depreciation was figured at 20 per cent., which was excessive so far as the wagons were concerned, but was probably close to the loss on animals. The cost of maintenance, including stable, feed, veterinary, help, shoeing, repairs, renewals, was $1.37 an animal a day. Thus to operate a wagon and two horses six days a week cost, with the driver, $5.63 a day. It will be seen that this total is economical when contrasted with the usual estimate of $6 a day for a two-horse outfit. The stable was of considerable proportions and it occupied space that was later utilized to excellent advantage in the yard, this being valuable for storage of lumber that should be protected. There was a decided gain in utilizing this building for other purposes. The wagons are all utilized and will continue to be useful for a long period of time to come.

The cost of the original tractor, including the reconstruction, was about $6000. The expense of the others was less than this because of the manner of building. The garage is an inexpensive structure and its equipment is not costly. It will serve for many years. The installation of the motor generator and the lighting system reduced the expense for illumination materially. Power is generated with fuel that was difficult to dispose of and accumulated rapidly. Aside from the initial expense the cost of lighting is much below what it was when the energy was bought from a central station. The batteries require but a small part of what is used each day in the plant. Mr. Sterritt says that he would increase the proportions of his generating installation were he to plan it again.

Considering the economy of the tractors: Assume the tractors and the equipment necessary for their use represents $30,000. Referring to the work for the 189 days it will be seen they are as efficient as 85 horses, which would cost at $275 each $23,375. The wages for the drivers of 85 animals would be $34,710 a year, and against this amount must be charged the wages of the five tractor drivers amounting to $3900 for the same period, or a saving in wages of $30,810 annually, without taking into consideration the lessened expense for tally men.

As to expense for depreciation. This item may be said to be unknown as yet, but if the battery machines endure as has that which was operated for 52 months before it was overhauled, the charge of 20 per cent. is much too large. In fact it would seem that half that amount would be a very liberal estimate. This is a reduction of 50 per cent. over the depreciation allowed for horses. The gasoline-electric tractors may depreciate more quickly, but the ratio is problematical as yet.

The cost for batteries is provided for by a contract which calls for such care, attention and renewals as is necessary to maintain a stated efficiency. The experience with tires has been very satisfactory, considering the large loads carried, for the weight is largely on the steel tires of the trailers, and the full elliptic springs, the comparatively slow speeds and ease of acceleration minimize the strains and the wear.

The possibilities of the tractors have been stated on a basis of actual work accomplished. But there is another phase to be considered. The machines have been shown to be the equal of 17 horses each for a length of time to insure a thorough test, and it is not improbable that they could do even more than what has been given as an average should occasion require. But in the periods when there is the least service for them they cost but a comparatively small part of the expense of maintaining horses and there is no depreciation. Not only this, the serviceability of the animal is measured by its life, while the actual measure of the work of the tractor should be mileage, dependent, of course, upon its upkeep.

Taking the figures stated for the results of 189 days' work, indicating that the tractors are each equal to 17 horses, and assuming that each does but half the average, this is better than eight horses and four drivers. The cost of this equipment for maintenance and operation at $5.63 each for every working day would be $23.93, or practically double the expense for the tractor.

The delivery equipment of the George W. Gale Company has attracted attention from the fact that the concern distributes all of its stock, both rough and finished lumber, by motor tractor, and visitors very frequently go over the plant and observe the methods and the work of what has been characterized as the best motorized lumber yard in America.

The Boston branch of the H. J. Koehler S. G. Company, recently made a sale of five Koehler commercial cars for export to West Africa. Manager W. H. Shutt was informed by the purchaser that this was a sample order, the purchase of others being contemplated for use there on the veldts.

STREET RAILWAY BUYS 29 ELECTRICS.

New York Public Service Corporation Will Install Big General Vehicle Equipment.

The New York Railways Company, the public service corporation that controls the street, elevated and subway transportation of the metropolis for Manhattan and the Bronx, has purchased of the General Vehicle Company 29 electric wagons and trucks which will be used for differing works. Three of these will be 1000-pound wagons with panel bodies, one will be a money wagon on a 2000-pound chassis, five will be 4000-pound chassis fitted with bodies and equipment for emergency service, 14 will be 3.5-ton chassis with dumping bodies for use in general construction work, four will be 3.5-ton chassis with the standard stake platform bodies, and two will be five-ton chassis with standard stake platform bodies. This order will be delivered as quickly as the work can be sent out from the factory.

The power used by the railroad is electric and the electric current can be provided wherever the machines will be located, for it is intended that they will be located at different stations with reference to the needs. The statement is made by Sales Manager C. W. Squires, Jr., that the number of electric vehicles bought by public service corporations has increased greatly within two years, and it is expected that the total number of machines owned by such companies will reach the 1000 mark in a comparatively short time.

EXCLUSIVE ELECTRIC GARAGE.

New York Edison Company Liberally Contributes to New Metropolitan Enterprise.

The exclusive electric garage that has been promoted by the New York Electric Vehicle Association will, it is believed, shortly be realized, for the plans for its establishment have assumed a tangible form and the enterprise will be inaugurated with the co-operative support of practically all of the electric vehicle interests in the metropolis. There are in New York today two garages that are given over wholly to business wagon service. That of the Yellow Taxicab Company is in East 25th street and the Acme Electric Garage is in East 32nd street. These two will accommodate about 125 machines, which is but a small proportion of the number in the city, which is estimated at considerably in excess of 2000.

Many of these, however, are kept in private garages, but with the rapidly increasing number of small delivery installations there is believed to be a demand that will justify the establishment of a garage of large proportions. The purpose of the association is to have a station in which all kinds of electric vehicles can be maintained.

The New York Edison Company has made an appropriation of $30,000 to make possible the establishment of the garage, this to be available in equal amounts for three successive years, and it is expected that with this fund it will be possible to open a station that will afford the character of service that will attract and retain patronage, and be, with the co-operation of the numerous interests, quickly self-supporting. It may be that the garage will first be established, and the interested concerns will assist in its development, and that later the plan for the centralization of the business of the electric vehicle companies will be worked out.

The New York Electric Vehicle Association is a division of the Electric Vehicle Association of America, and it is understood that the expenditure of the fund placed at the disposal of the organization will be through the office of the national body. Arthur Williams, general inspector of the New York Edison Company, is president of the Electric Vehicle Association of America, and it is but natural that the company should be represented by him. In connection with the garage it is intended to decidedly increase the facilities for the use of the electric vehicle in New York.

CASE LEAVES LANSDEN COMPANY.

Move Disposes of One Set of Rumors and Brings to Light Another.

W. L. Case, vice president and general manager of the Lansden Company, Newark, N. J., maker of Lansden electric vehicles, has resigned his position and his place has been taken by George E. Blakesley. It is understood that Mr. Case has disposed of his holdings in the company and will return to his consulting engineering practise after a trip through the South.

The Lansden Company was established about 10 years ago to develop an electric truck utilizing the Edison nickel iron batteries. After the International Motor Company took over the Mack plants at Allentown, Penn., a number of those interested in the latter business formed a syndicate to buy the Lansden Company, and it was taken over in January, 1912, when Mr. Case, who had a considerable part in the formation of the International company, was placed in charge.

Mr. Case's resignation would appear to set at rest rumors which have been persistently circulated that the International company was to absorb the Lansden Company. That this supposition is without foundation seems to be further confirmed in the eyes of those interested, by the fact that Mr. Blakesley is said to be closely associated with John M. Mack, who although at one time a strong factor in the International company, has for the past few months been inactive in its management.

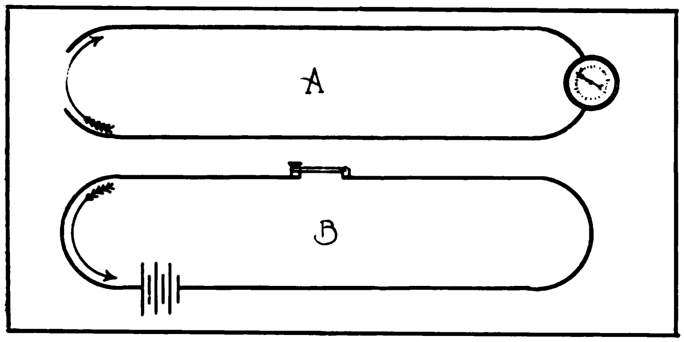
There is said to be some prospect of the formation of a new consolidation of the Lansden, the Mack and the Webb companies, all of which are owned by Mr. Mack and his associates. This possibility, however, has received no encouragement by those most intimately interested.

ELECTRIC VEHICLE PRACTISE.

The Principles Governing the Application of Current Electricity for Motor Propulsion, the Units of Electrical Measurement Ordinarily Used, the Theories of Design and Qualities of Common Motors and Dynamos

By William W. Scott.

THE simplicity of the electric vehicle is such that it is not necessary for the owner or operator to acquire technical knowledge, but it is desirable, because of their very general and constantly increasing use, that electrical definitions and units of measurement be understood. While electric activity may be classified as static and current electricity, the latter is the form with which the user of the vehicle will deal, and this is the continuous passage of energy from a point of high potential to a point of low potential, there being a constant source of electromotive force.



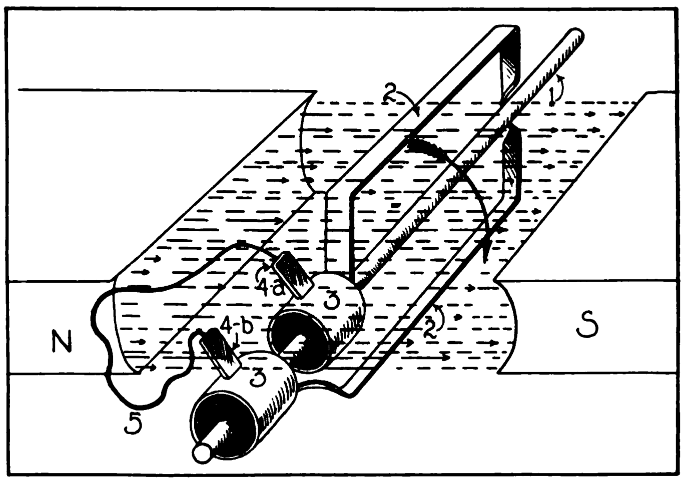
Inducing and Induced Current: A, Circuit Through a Galvanometer, in Which a Current Is Induced by a Current in B, Created by a Battery, When a Switch Is Closed—Arrows Indicate the Flow of the Induced Current Is in Reverse of the Inducing Current.

The electric energy utilized in motor vehicles is mechanical movement converted into electrical current, and in the operation of the vehicle this current is again converted into mechanical movement, the dynamo being the source of the current stored in a battery of cells, and the motor being the means by which the current from the battery is transformed into mechanical movement or power. It will be noted that the function of the motor is to reverse the operation of the dynamo, and this statement expresses precisely the characteristics of the two machines. But it is possible to operate a practical dynamo as a motor by simply changing the position of the brushes.

Mechanically generated electrical energy is a result of induction, and this may be explained by assuming a circuit of wire connected to a battery in which circuit is a switch that may be opened and closed, and a second circuit of wire that is through a galvanometer. When the first circuit is closed and the current moves from the positive to the negative pole of the battery, a weaker current will be induced in the second circuit, if within the range of influence, which will move in the opposite direction, but for a very brief period. If the battery circuit is then opened and the galvanometer observed, a second current will be noted, weaker and briefer than the first, but flowing in the opposite direction to that first seen. The strength of the currents will be proportionate to the strength of the inducing current, and to the proximity of the circuits. But if the circuits are sufficiently separated the weaker current will move in the same direction as the stronger. Again, a low resistance wire in the inducing circuit and a high resistance wire in the induced circuit will cause a greater electromotive force in the latter than in the former. Or this result may be reversed by the condition of wiring.

When polarity exists a metal may be said to have magnetic influence and there is a constant flow of current from the one pole to the other. The dynamo is a temporary magnet, and as built it has pole pieces between which an armature revolves, breaking or interrupting the lines of magnetic influence that are passing from the positive to the negative poles. The pole pieces of the motor are converted into electro magnets during the time the machine is in operation by a current sent through the windings of these pieces. The pole pieces are known as well as the field pieces.

The theory of the dynamo, so far as the principle of induction is concerned, may be observed in an accompanying drawing, which represents as N and S the north and south pole pieces of a machine, between which flows a current of magnetism from north to south so long as the pole pieces are magnetized. Between these is shown a shaft 1 on which are two segments 2 that, it will be noted, are connected with the rings 3 on the shaft 1. Contacting with the rings are the brushes 4 a and 4 b, from which current is taken through the cable 5 to the circuit in which it is used.

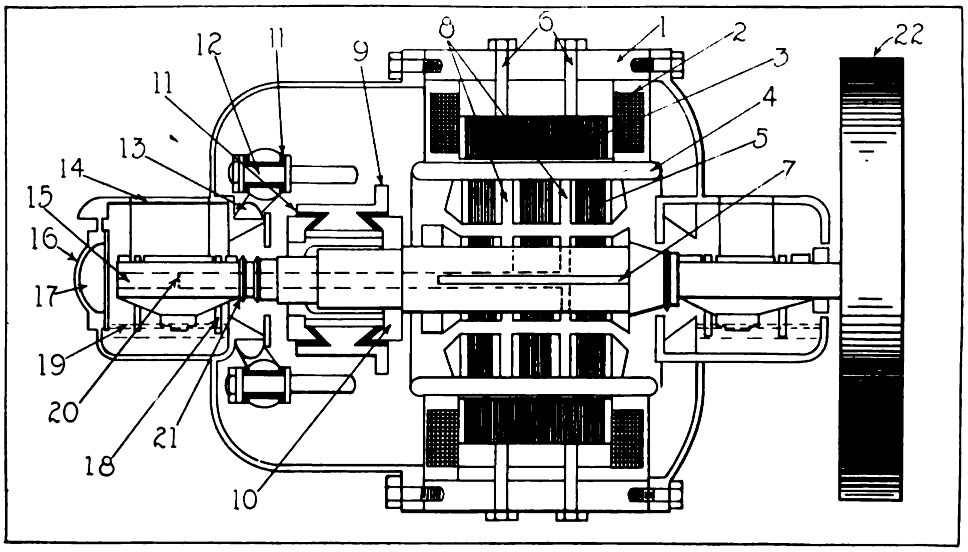


Sketch Illustrating Dynamo Functions: N, North Pole; S, South Pole; 1, Shaft; 2, Segment of Armature; 3, Collecting Rings; 4 a and 4 b, Brushes; 5, Current Supply Cable.

This form of dynamo would produce an alternating current. The shaft 1 merely carries the armature, which is represented by the segments 2, and the rings 3 are insulated so that the current is collected by the brushes 4 a and 4 b and carried off on the cable.

The armature in practise is made up of a large number of segments, and when it is turned the segments will cut or interrupt the lines of force or magnetism flowing between the north and the south poles. As shown in the drawing the segments are at right angles to the lines of force and at that point offer the greatest obstruction to the flow of the current, while they do not obstruct it when turned in the direction of the flow. With the revolution of the shaft the current induced in the circuit formed by the segments and the brushes and the cable connecting the brushes will be constantly changed in strength and direction as the segments approach and recede from the pole pieces. Because of this variance the current will alternate in its delivery to the cable and flow in opposite directions, rising from zero to maximum and subsiding to zero so long as the movement of the segments is continued. The current is changed to flow in one direction by the addition of a commutator. The description is intended to illustrate the principle only, for in practise the armature consists of a considerable number of segments and the lines of force are separately interrupted by each of these as the armature revolves.

The dynamo generates the electric power from mechanical movement and the motor reconverts it into mechanical movement. In construction they are practically the same, both having the field magnets in pairs or in multiples of two with opposed poles and the pole windings connected in series; the armature that revolves between the field pieces and interrupts the lines of force, the exposed ends of the magnet cores that form the pole pieces, the commutator that collects the current, and the brushes that contact with the commutator and serve as the terminals for the circuit through which the current is delivered.



Electric Motor, Shown in Longitudinal Section: 1, Magnet Ring; 2, Field Windings; 3, Field Magnets or Pole Pieces; 4, Armature Winding; 5, Armature Core; 6, Bolts Retaining Field Pieces; 7, Shaft Keyway; 8, Air Circulation Ducts; 9, Commutator; 10, Commutator Retainer; 11, Insulation; 12, Brush Stud; 13, Brush Rocker; 14, Inspection Plate; 15, Air Circulation Duct; 16, Air Filter; 17, Air Inlet; 18, Oil Rings; 19, Oil Level; 20, Fan; 21, Oil Distributing Rings; 22, Pulley.

The dynamos customarily used are series-wound, shunt-wound and compound-wound, but there are other types that are designed for special purposes, these varying as to the construction of the armature, the form of field windings, and in other detail with reference to the uses to be made of them. Of those specified the series-wound type are constructed with the two poles of the magnets wound with a small number of coils of a heavy low-resistance wire, one end of which is connected to one brush and carried around both pole cores and to the outside line and to the other brush. With the shunt-wound machines the pole cores are wound with many coils of a high-resistance wire, and the field windings form a shunt circuit from the main outside circuit, the terminals of which are the two brushes contacting with the armature. These brushes are connected with the terminals of the field windings. The compound-wound dynamos combine the construction of the two mentioned, the field magnets being double wound with a small number of coils of a heavy low-resistance wire, which is arranged in circuit as in the series-wound machines, and with a second winding that is identical with that of the shunt-wound dynamo.

While the pole pieces of the dynamo of the series-wound type are not magnets until excited by the electric current passing through them, there is generally a sufficient degree of energy retained in them, which is known as residual magnetism, to cause the generation of current as quickly as the armature is moved. That is, there remains in the pole pieces a slight magnetic influence that is moving from the north to the south poles, and these lines of force, when interrupted and directed through the field windings, will so intensify the current and the electromotive force that the dynamo can be started and will begin to generate current until the maximum of speed has been reached and the machine is producing the greatest degree of electric power. The statements made relative to the dynamo can be applied equally well to the motor, as will be explained later.

The units of electrical measurement are regarded as being as accurate as engineering science could devise and these are stated in what are known as the C. G. S. units, which represent length in centimeters, weight in grams and time in seconds, and they afford a means of accurately estimating the proportions of current strength, circuit resistance and voltage. It

may be well to point out that the units permit a very precise estimate of the power efficiency under given conditions on a given circuit, from the fact that the working energy available, expressed in amperes, is exactly proportionate to the voltage and resistance of the circuit and to the efficient activity in terms of work accomplished and time required.

The unit of resistance is the ohm, which is equivalent to the resistance to one volt of electromotive force by a column of mercury 106.3 centimeters in height and one square millimeter cross section, at a temperature of 39 degrees Fahrenheit or it is equivalent to the resistance of one foot of No. 40 B. & S. gauge copper wire. From these two standards it is possible to determine the resistance of any conductor with reference to length and cross section and to make accurate comparison of the resistivity of any conductors of differing dimensions.

The ampere is the unit of current and this has been established as the strength of current that can deposit .00033 gram of metallic copper, using the electro-plating process, in each second of time. It will be noted that this designates the intensity of the current, which may be taken as its working energy, as well as the time for a given work. From this basis it is possible to estimate the power for any period, though the phrase ampere as applied to electric vehicle work is often meant to express ampere-hours. The ampere-second is represented by the coulomb, which is technically used to express electrical volume, it being the equivalent to the product of the amperage of a current by the number of seconds of flow.

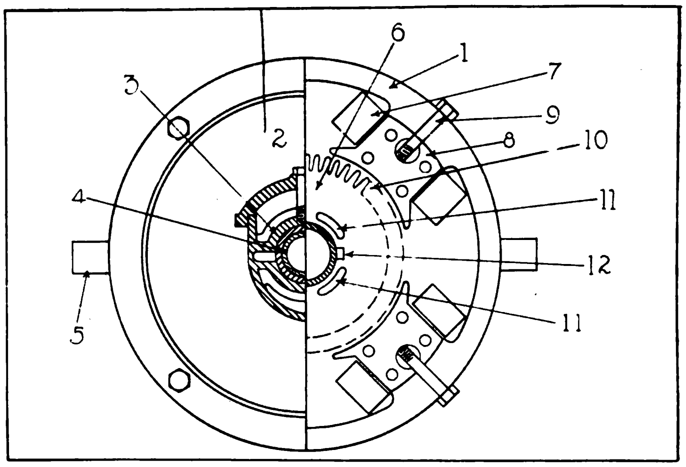
The volt is the unit of pressure and this is determined with the units of current and resistance. One volt of electromotive force can produce a current of one ampere on a circuit having a resistance of one ohm. This is the actual standard, and where voltage is stated it may be regarded as a known quantity, or it may be an equivalent estimated on the capacity of a type of galvanic cell. It is not necessary to define Ohm's law with reference to electric energy, for it has been sufficiently expressed to meet all requirements of those using or operating electric vehicles.

The unit of activity is the watt, which indicates the rate of energy of one ampere of current under a pressure of one volt, and represents the product of the voltage by the amperage. There are other expressions of the value of the watt, which may be the product of the resistance by the square of the current, or the quotient of the square of the resistance by the voltage. Generally the operative capacity of an electric motor is expressed in watts or kilowatts, and 746 watts is taken as the equivalent of a horsepower.

In the use of electric vehicles, however, there is seldom need for the accurate figures that can be obtained from these units of measurement. The voltage is determined by the voltmeter, the amperage by the ammeter, and the watts by the wattmeter. These indicating instruments are very accurate and dependable and of course vary with the use to be made of them, some on the vehicle and some in the garage in charging the battery.

The dynamo has been described because it is the source of production of the current, and the principles have been outlined that the generation of energy may be understood, but in the use of the vehicle the motor is to be considered. This machine is, as has been stated, practically the same as the dynamo and differs only in the position of the brushes. With the dynamo the residual magnetism is sufficient to excite the field windings and the pole pieces when the machine is started to generate current, and this current will in turn further energize the pole pieces and convert them into strong magnets.

But with the motor there will be also a residual magnetism, and this is augmented when the current is supplied to the windings of the pole magnets and the windings of the armature. The opposite poles of the armature are attracted by the magnetic action of the pole pieces and the armature is rotated. In the dynamo the lag of the current to a certain extent resists the rotation of the armature, but with the motor this becomes a magnetic drag that is the propulsive force, turning the armature and constituting the influence that the magnetic field exerts upon the armature wiring, through which the current from the line is flowing.



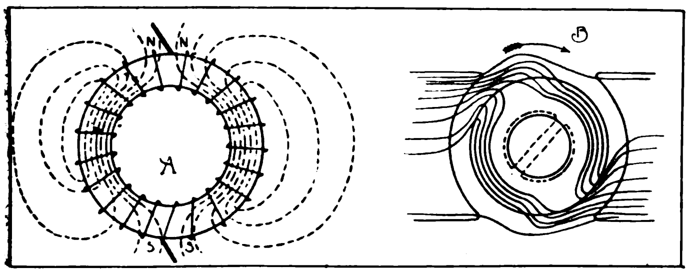
Four-Pole Electric Motor, Partial Section: 1, Armature Shell; 2, End Plate; 3, Armature Shaft Bearing; 4, Brass Sleeve; 5, Supporting Lug; 6, Armature Core; 7, Field Winding; 8, Field Pieces; 9, Field Piece Retaining Bolt; 10, Channels for Armature Windings; 11, Air Circulation Ducts; 12, Keyway.

As the armature is caused to rotate between the pole or field pieces, and the magnetic action assists that rotation, the interruption or cutting of the lines of force creates or produces a counter electromotive force, which is increased as the speed of the armature increases. This results from the strengthening of the magnetic field and the large number of lines of force created. But as the armature speed is increased there is a lessened resistance to its motion, and because of the greater counter electromotive force less energy is absorbed. As the load is placed upon the motor and the armature speed is retarded the counter electromotive force generated is less and there is a corresponding increase in the energy absorbed.

The electromotive force produced by a dynamo is

proportionate to the number of turns of wire wound upon the armature and to the speed of rotation within certain limits. As the rotation of the armature produces a series of reactions between the windings and the magnetic field, the armature is transformed to a magnet that is polarized constantly at certain definite points in its rotation. These points of polarity are, according to the accepted law of induction, at right angles to the lines of force, and as the neutral points are the points of contact between the brushes and the commutator, where the current leaves and re-enters the winding of the armature, the armature is constituted two separate magnets with two north and two south poles, each pair of poles being an equal distance from the contact of the brush. The two north and two south poles really serve as single poles and at the extremities of the diameter of the armature cause the distortion of the lines of force with the rotation of the armature.

The induced polarities of the armature, the one resultant from the induction from the field and the other from the induction from the armature winding, cause the distortion of the magnetic field, and the current moves from the north poles of the armature windings through the armature to the south poles, and thence



Movement of Lines of Force: A, Direction of Lines of Force and an Induced Current in the Polarizing of a Rotating Dynamo Armature of the Ring Type; B, Distortion of the Lines of Force Passing Through the Rotating Dynamo Armature.

through the pole pieces of the magnetic field to the north poles of the armature, forming currents moving in opposite directions at either side of the contacts of the brushes. The induced current in the armature moves at right angles to the direction of the inducing current in the windings. With the motor, however, the electromotive force moves in the armature in a direction opposite to the current. As before stated the current supplied to the circuit, influencing the windings of the motor armature and the windings of the pole magnets, causes polarity in both, and the magnetic action is attraction of the opposite poles of the armature, which exerts a propelling effect or driving force.

The power of a motor is proportionate to its speed and to the torque, which is the effective energy that may be exerted upon the pinion or gear secured to the end of the armature shaft and through which the driving effort is applied. This power is measured by pounds weight, the diameter of the pinion or gear and the number of revolutions a minute.

The qualities demanded of the electric vehicle motor are that it shall have a high efficiency though having low power rating, that it can be operated under different pressures and at different speeds, that it give service without fuses, cut-outs and other protections, and that power be produced uniformly under differing loads. In the operation of such a motor it is frequently required to endure an overload of several hundred per cent., and the protection that might be afforded with a machine used for other purposes would serve when the greatest work was necessary. The greatest power is required in climbing grades or on rough roads, and at times a driver will start at high voltage with a very heavy load or under conditions that will tax its capacity to what may be regarded as the extreme. The motor must have the greatest strength, be as light as it is practical to make it, and it must endure the stresses of operation with the least possibility of wear or damage. The accessibility of the motor is another important factor, so that the commutator and the brushes may be examined and adjusted, cleaned or repaired.

In the installation of the motor in the vehicle the connections made between the machine and the battery are always flexible, which is insurance against crystallization, short circuits, and other damage that might result from vibration. The rotating parts are always mounted on ball bearings and lubrication is provided for by oil wick cups or adjustable compression oilers. The motor is always enclosed in a substantial housing, usually a shell of steel, in which it is protected from the abrasive influences of dust and other accumulations.

The machines generally used for motor vehicles are the series-wound type, which form is regarded as being extremely efficient and practical as well as meeting with all ordinary requirements. One quality especially desirable is that it will automatically adjust the consumption of power to the load, consuming a small current with light loads, and as the resisting torque is increased the power needed for the work is constantly absorbed, so that there is high efficiency when the overload is very large. It will require more power when climbing grades, however, than will other types. In this type, as the total internal resistance is equal to the combined field and armature resistance, the current consumption is the same under an even load at any speed, and the torque is approximately proportionate to the current. When used with a light load and small current the speed of the armature is high comparatively, which, because of the creation of a high counter electromotive force, reduces the current supplied from the battery proportionate to the difference between the impressed voltage and the internally generated voltage. Thus, while the efficiency is lessened with light loads and at high armature speeds, with heavy loads and decreased armature speeds the efficiency is increased. This has caused the construction of machines that will produce power proportionate to the weights, and have comparatively slow speed of the armatures.

(To Be Continued.)

TRUCK ECONOMY IN COAL DELIVERY.

Six Electric Machines Installed by the John E. Cousens Coal Company, Brookline, Mass., Since July, 1910, and Maintenance of Regular Horse Equipment, Is a Striking Illustration of the Possibilities of Business Building.

ECONOMY of delivery is usually determined by a comparison of the cost figures so far as these may be known. The assumption is that each represents a satisfactory standard of measurement, and a statement or chart is believed to convey a clear knowledge of the possibilities. Business men profess to believe that an animal equipment as operated is to be accepted as the most practical and economic in the conditions in which delivery is made. Taking the majority of delivery services, it is certain enough that system will yield a considerable saving and probably somewhat increase efficiency, which conclusion is obvious enough if analysis be made of the subject under consideration.

To illustrate: A concern having a transportation department rarely has accounting that will show expense detail even in a general way, and in many instances this cost may be covered by two or three general accounts. It is not possible to economize unless every item of cost is known and charged, and credit is made for the work performed at definite and accurate prices. It is exceedingly probable that as nearly, if not quite, all business concerns regard their deliveries as a necessary expense, and seldom if ever in any way productive, there is held to be no reason why the cost should be increased by additional clerical work. That is, the accounting of the expense of delivery would not effect an economy.

This, however, is an error that has cost enormous sums in the aggregate. With a definite knowledge of the expense of any work it is practical to adapt methods that may economize. Unless endeavor shall be made to minimize cost and a standard is known by which to measure a result, it is impossible to reach any satisfactory conclusion. Large corporations engaged in transportaton work have kept reasonably accurate account of expense with reference to locality and general work, and concerns of these proportions can make comparisons sufficiently certain to justify conclusions as to economy.

With rare exceptions, however, the business that is confined to a restricted area has no data that can be accepted as applicable to similar businesses in other places. Generally transportation expense is based on animal service that costs a given amount annually and there is no record of the work actually performed. Instead of cost a unit, whatever the form may be, and with reference to the character of delivery, a stated sum may, and often does, represent all charged expense for haulage.

There is no business that requires a greater ratio of delivery with relation to sales than the coal trade. The proportion of customers who haul their own supplies from the yards is very small. The haulage service of every firm is variable and the orders vary greatly. The small dealers, however, who sell in small quantities, are not to be considered in this article. The

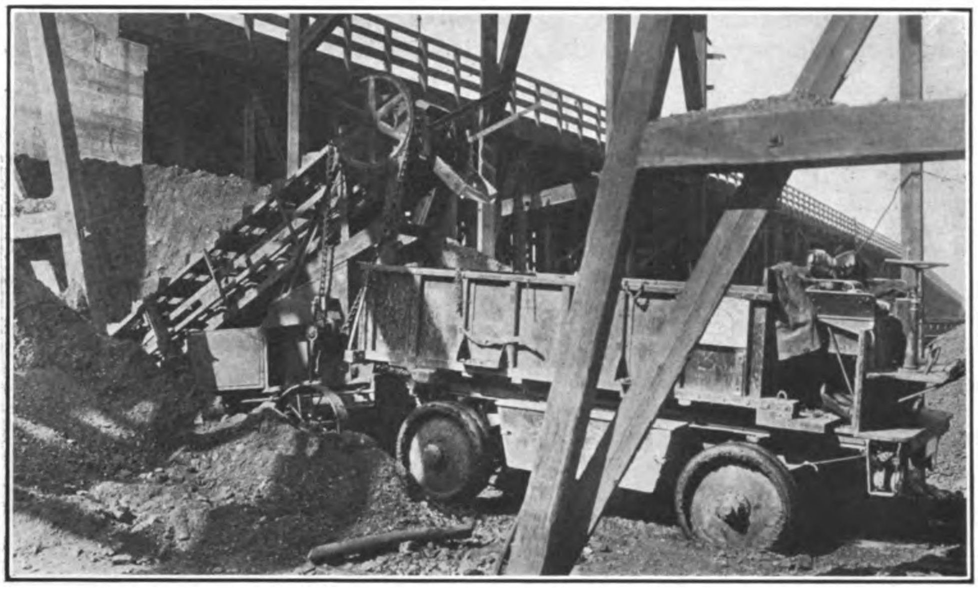
Couple-Gear Truck Under the Anthracite Coal Pocket of the John E. Cousens Coal Company, Ready for Gravity Loading.

family orders are occasional and the sales to shops, mills, hotels, apartment houses, office buildings, public service plants and the like require frequent and sometimes daily deliveries. The distribution to families means that the service requirements may fluctuate materially. The contract deliveries are more certain and the work can be better systematized.

In the large cities the cost of delivery is increased through the traffic conditions and regulations, by the character of the streets, by the manner of discharging the loads, etc., and this is offset in less populous communities by the greater distances, the less improved highways and the topography. The loss of time by motor vehicles in short hauls and congested traffic has

created the impression that horses are more economical because of the lesser cost and the delays that cannot be avoided. Experiments with motor trucks have generally been made by working the machines under the same conditions and with the same facilities as have been used for horses, and with so few a number that the cost was necessarily larger than would have been realized with a completely motorized delivery.

The John E. Cousens Coal Company, 781 Commonwealth avenue, Brookline, Mass., has a business that is peculiar in that it is partly in Boston and partly in the town of Brookline. Some of the deliveries are made as far into the city as the vicinity of the Boston common, and some are made in all sections of the town. The distribution covers a large area, and while a part is made under conditions that may be said to obtain in cities of large size the remainder is made in highways that are comparatively free from traffic, but are on hills having grades running as high as 10 per cent. Considering the widely differing conditions it may be said that the average cost of delivery is somewhat larger than would be experienced in a town, and will probably closely approximate that of the firm doing business in a city of large size.



Loading Coal with an Electric Loader at the Yard of the John E. Cousens Coal Company—A Decided Saving in Time.

This company receives its coal by barge at its dock in the Charles river and the orders are distributed from its plant at what is known as Cottage Farm. The cargoes are piled beneath conveyors or stored in pockets and handled in the usual manner. Practically all the anthracite coal is loaded from the pockets into the carts by gravity and loading machines are used to fill the carts from the piles of bituminous coal. The stable equipment of the company has averaged 56 horses and wagons and carts with capacity up to five tons.

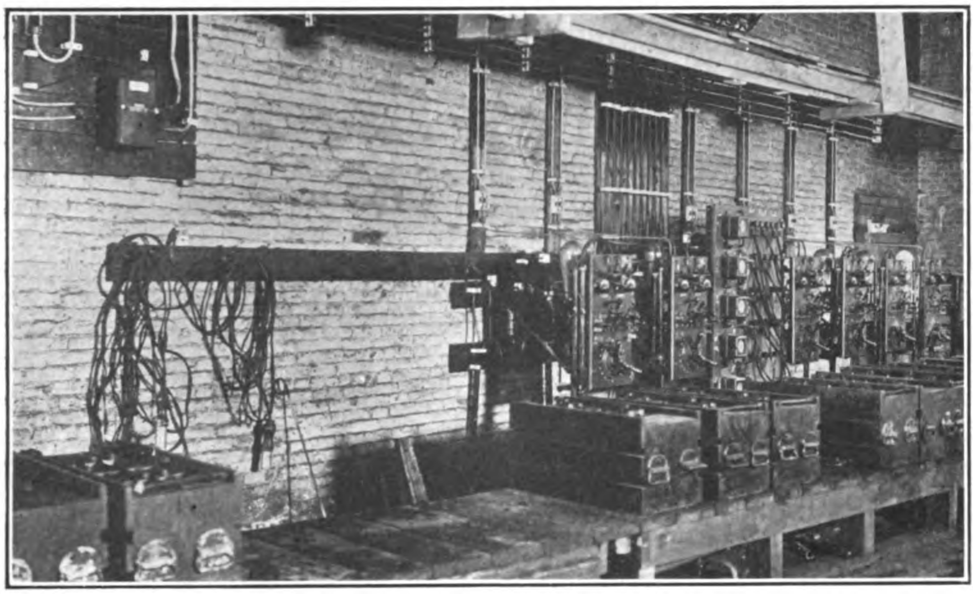
The horses were used exclusively until July, 1910, when the first motor truck, a five-ton Couple-Gear battery driven machine, was delivered. The company had had for a considerable length of time an accurate knowledge of the cost of horse distribution and when the truck was ordered a record was devised that would, it was expected, give dependable data of the truck expense. The intention was to work the truck as constantly as was practical, and a second battery was purchased so that a change could be made at noon and without loss of time. The original body was not fitted with a hoist, but later on one of the manual type was installed. The lack of quick discharging facilities was a handicap in the first use of the truck and this was realized the more with the fitting of the hoist.

The intention was, if the machine was found economical, to purchase others, and in a sense the work was experimental. The charging equipment was temporary in character and the truck was garaged at the yard until results could be satisfactorily determined. The use of trailers was thoroughly experimented, several carts of three and five tons capacity were utilized, being fitted with rods extending from the rear ends of the chassis frame side members to the equalizer of the wagons. With short poles to steer them the carts were found to handle admirably and the truck could haul its load of five tons and a trailer with a similar freight without appreciable loss of time as compared with trips without the trailer.

The truck was used for the long hauls and when not required for this class of work was sent out with family orders. The average daily mileage was 35 and the tonnage was from 20 to 25 tons with long trips and from 30 to 40 tons with short hauls. The trailers were fitted with dumping bodies and when large loads were to be delivered there was but little loss of time. In some instances a trailer was loaded for one delivery and this was hauled to the customer and uncoupled for unloading, the truck continuing on to another and picking up the trailer on the return trip. Where orders could be sent out in this manner the truck was extremely economical.

The record of work and expense kept by the company was such as to make possible a very satisfactory comparison of both the truck and animal vehicles and a second truck was ordered that was delivered in June, 1911. At that time the necessity of a garage was evident, and the company leased an abandoned roundhouse of the Boston & Albany railroad, on property separated from the yard by the Cottage Farm bridge approach, with the intention of using a part of it for storing the machines and the remainder for storage.

The roundhouse is considerably below the level of Commonwealth avenue and a horseshoe curve of steep grade affords access to it. One section of this was made a garage and in this was installed a pair of charg-



Charging Panels and Mercury Arc Rectifiers in the Garage of the John E. Cousens Coal Company.

ing panels and a motor generator loaned by the Boston Edison company pending a permanent installation. The second truck was equipped with two batteries. As the battery cradles of the trucks were underslung and side loading two platforms were built the height of the bottom of the cradles and the width of the battery trays, so that a truck could be driven between them and the exhausted battery removed at one side. Moving the machine ahead five or six feet the charged trays were placed in the cradle. The process was repeated on the other side. This eliminated lifting and facilitated handling and prevented a possibility of damage in changing.

The company employed an experienced battery man and mechanic and placed him in charge of the garage with instructions to keep the trucks up to the highest standard of efficiency and to devise such methods as might be productive of economy. The work of delivery was continued with trailers when this was possible and it was found that while these were economical with large loads to be delivered to one customer it was necessary to send a sufficient crew with them to handle the freight without loss of time for the truck, and where a trailer was taken out and left where it was necessary for the machine to lose time in returning for it the saving was materially lessened. If the trucks were not sent for the trailers and horses were sent out to haul them back to the yard there was the time of the men and the animals to be considered.

In the use of trailers the experience was that they could be used to good advantage where a load was to be delivered to one customer, or to two close together, especially if the loads could be discharged quickly and the trucks kept in operation, but in a business where the orders vary constantly it is not practical to use trailers where the loads are delivered a considerable distance apart and the truck must haul the trailer back. The company tried out the use of trailers consistently and for a sufficient length of time to insure a definite knowledge of economic work, and the decision was that trailers could not be profitably used unless the deliveries were to single customers or so close together there would be very little, if any, lost time for the machine. While hauling trailers did not materially decrease the speed of the trucks and very nearly the same time could be made as when the machines were used alone, there was naturally an increased wear on tires, and this was another item of expense that could not be overlooked.

When not hauling trailers the trucks were very economical of tires from the fact that traction is by all four wheels and there is an equalization of the strains of tractive effort, and in starting the power is exerted very gradually. Although the streets of Brookline are very hilly and the loads carried were large, the tires gave excellent satisfaction.

The third truck was ordered and was delivered in August, 1912, this being of the same type as the others and fitted with a dumping body. The machine

Remarks:

Form 1—This Being a Record of the Number of Trips and Tonnage of Each Truck for Each Day of the Week.

was placed in the same service as the others and it was utilized so far as possible for the longer hauls and, whenever necessary, for delivering family orders. The third charging panel was installed in the garage and the motor generator was sufficient to meet the requirements for energizing the batteries. The platforms for the batteries were increased in length and a system of charging was established so that in the morning when the trucks went out they each had a battery that had been charged in the machine during the night. At noon these were removed and the other batteries, which had been charged the afternoon previous, or during the morning, installed. When the trucks were brought in at night the batteries in them were charged without removal, and these were again used the next morning. This necessitated two charges and discharges of a battery one day, and one charge and discharge the next.

The time required for a change of battery varies from 12 to 15 minutes, and it may be said that 14 minutes will be an average. Time is taken from the entrance of a truck into the garage until it leaves the door going out, and as this work is done at noon when the drivers have an hour, it will be understood that rarely, if ever, is there any delay or loss of efficiency. The fourth and fifth trucks were ordered and were delivered in October and November, and with these in use the charging installation was changed. The motor generator was removed and three panels additional were installed, each fitted with a 5-50 mercury arc rectifier, and the current taken from the alternating current of the main line feed that was brought into the garage. Two of these are arranged to be coupled so that a current of 100 amperes may be used if it is necessary, and with two spare batteries this afforded a sufficient reserve for all emergencies that might arise. In the use of these trucks the battery platforms were extended to take six batteries at either side, and this afforded all the space necessary in handling them.

The sixth truck was delivered to the company directly after the close of the Boston motor truck show, and this is now in service. It differs from the others in that it is driven by the front wheels only and it is expected to have a daily mileage of 25 with a single battery charge or perhaps twice that with a change of battery. The machine is a type that has been used by a number of coal firms in Boston and it carries the load on the rear wheels, which are shod with steel tires. The purpose is to test this machine in the same service with the others and to learn wherein it differs so far as the economy of work is concerned. With this machine the full charging capacity of the garage is utilized according to the system of charging inaugurated, but it is by no means up to the maximum service that can be obtained by using the panels constantly. Of course, with the increased use of the rectifiers their life is necessarily shortened in number of days, but each can be expected to afford an approximate service.

In adapting the roundhouse to the needs of the company as a garage but one division was necessary, and that will house more than the present number of machines in use. Aside from the charging panels and the battery platform a work bench with an equipment of hand tools is practically all that is needed, and the only spare that is kept on hand is an extra wheel, which contains a motor. In the event of a motor defect developing in a wheel it is removed and replaced by the spare, an operation that can be accomplished in three hours or less, and the defect is remedied and the restored wheel replaced.

The machines require attention in oiling and greasing, and adjustments are made where wear is evidenced. Naturally all bolts are kept tight and the

Lost Time						

Form 2—A Comparative Record of the Work Accomplished with Each Truck for Each Week.

trucks are gone over regularly to insure that no condition of deterioration has developed. They are under the constant observation of the manager of the garage and each driver reports to him when the trucks are brought into the garage if there is any condition of operation that seemingly requires attention. Each vehicle is expected to be ready for service the morning of every working day and lost time is carefully guarded against.

The record kept of the trucks is shown on several forms that are filed in the office and are exceedingly simple. What may be termed Form 1 covers a period of a week and under each day is noted the number of trips made and the tonnage carried by each truck, and below this is entered any fact that may be necessary to explain a discrepancy or variance from the work that may be ordinarily accomplished.

Form 2 is known as a "Weekly Comparison of Performance" and indicates for the noted period the number of trips, miles driven, tonnage, ton-miles driven, ampere-hours of electric energy used and the lost time for each truck. Some of the facts shown by this sheet are taken from Form 1.

Form 3 is kept in the garage and at the end of the week is sent to the office. Against each truck is a daily statement which shows the number of ampere-hours of electric current supplied to each battery and the total for the two, the odometer reading taken at night, the time required for changing batteries, the lost time and a note of any circumstance that may need explanation. Six of these statements appear on a single sheet and these supply the remainder of the facts for Form 2.

A record is kept of the current supplied to the batteries as shown by the readings of the sangamo meters, giving the number of the truck and the ampere-hours supplied by day and by night. This covers a period of a week and is filled by the manager of the garage. The record states: "This is a record of the total amount of electric current supplied the batteries, as indicated by the readings on the sangamo meters on the switch board for the week ending ———." "Note—It is understood that all current, whether in the batteries on the benches, or supplied to the batteries in the trucks, goes through and is measured by the meter on the switch board." From this record is filled the other data required by the three forms stated above. In the garage is posted a record of "Work and New Parts," on which is entered the different parts renewed and the date and number, and the number of the truck, it being understood that there is labor involved in making such replacement or restoration. This record is shown as Form 4.

The company has worked five trucks, one of them since July, 1910, and each machine is rated as the equal of at least three two-horse teams and carts, and while this equipment has been added gradually the number of horses in service has not been decreased. With the advent of the sixth machine there is no apparent reason to eliminate any of the animals, and it will be understood that the company has sufficiently increased its business to require the six machines, which can be considered as equal to 40 horses, since the trucks have been used. This conclusion is obvious, for the company has retained all its horses and has added to its motor equipment. The machines have made possible the development of business that was not previously within the area where it could be profitably developed.

The company regards the cost figures of its motor delivery service as an asset of its business and is not

willing to state these, but the statement is made that its experience has been that the figures follow very closely the estimate of the manufacturers of the machines. The estimate is as follows: Driver, \$2.50; current, \$1.60; tires, \$2.35; batteries, \$2.67; new parts and repairs, 50 cents; depreciation at 10 per cent., \$1.33; fire insurance, 40 cents; liability insurance, 32 cents; floor space at \$50 a year, 17 cents; supervision, 50 cents; interest at 5 per cent., 50 cents; a total daily cost of \$12.84 a machine. With an average mileage of 40 and carrying five-ton loads this gives 100 ton-miles daily, at a cost of 12.84 cents a mile.

All of the garage work is done by one man with such assistance as he may from time to time require, and he also gives attention to two automobiles used by the members of the company. The attention to the batteries is practically confined to equalizing them with distilled water to restore what is dissipated through evaporation, and there is a contract with the agent for the truck that when the efficiency of the batteries fall below 90 per cent. the plates are renewed.

DEMONSTRATING KELLY LINE.

California Agent Adopts Novel Method of Showing Two Models at the Same Time.

A novel method of showing the different models of Kelly trucks, made by the Kelly-Springfield Motor Truck Company, Springfield, O., has been originated by Frank G. Miner, manager of central and southern California for this line. The two principal models at present are the one and three-ton vehicles.

When Mr. Miner starts out to make a demonstration to a prospect, he places the one-ton truck on the body of the three-ton machine and is thus able to show both vehicles at the same time. This method has attracted considerable attention at San Francisco, which is Mr. Miner's headquarters.

REPLACES TEN TEAMS.

Knox-Martin Tractor Proves Successful in Handling Work of San Francisco Concern.

A Knox-Martin tractor, made by the Knox Automobile Company, Springfield, Mass., recently delivered to a big trucking company at San Francisco, Cal., has been carrying 9.5 tons on each haul, displacing 10 teams formerly required for the work with such satisfactory results that the firm has decided to install Knox tractors in place of all their horses as fast as possible.

The tractor has solved the problem of drayage in San Francisco because it is so well adapted to this class of work and has not necessitated any change in the present method of handling freight and merchandise. The same trucks that were formerly used in the work with horses are now being operated by the tractors with remarkable results in both tonnage capacity and economy.

FINDS TRUCK EFFICIENT.

Interesting Figures Compiled by Chicago House After Year's Use of KisselKar Vehicle.

Henry Frerk Sons of Chicago, dealer in building materials, coal and feed, has operated a four-ton KisselKar truck, made by the Kissel Motor Car Company, Hartford, Wis., during the past year. The vehicle has replaced two double and one single horse teams and the figures compiled are interesting.

The truck was in service 263 days and covered 10,241 miles, an average of 39 miles a day. The average weight carried a load was 7225 pounds. One gallon of gasoline was used for each 28 miles and the tire expense a mile was five cents. The firm finds the machine is of particular value in taking care of distant deliveries quickly, thus materially widening its field of service.

MOTOR TRUCKS AND GOOD ROADS.

President Willys Foresees Decided Benefit as Result of Governmental Assistance.

Though few people are aware of the fact, that the national government gave the motor truck industry substantial assistance last September, when Congress passed the postoffice appropriation bill, is the opinion of John N. Willys, president of the Gramm Motor Truck Company, Lima, O., maker of Gramm trucks. Attached to this bill was a rider, which aroused very little comment, mainly because its importance was not understood, providing for the building of good roads throughout the country, the work to be carried on in conjunction with the efforts of local authorities in the various states. Mr. Willys says:

"Not only does the primary idea of the bill, the improvement of roads throughout the country through federal aid, mean a vastly increased field of operation for power vehicles, but the actual work when it is undertaken will open a greater opportunity for the use of motor trucks in road buildng service. The plan outlined in the government measure is an excellent one. It calls for an appropriation of \$500,000 to be spent in improving roads selected by the government, over which rural delivery is or may hereafter be established. Each state in the Union is to be allotted about \$8000 for the improvement of two post roads each year, with a reserve fund of \$2000 to be spent annually in the maintenance of such roads.

"All over the country the practicability of motor trucks in road building has been proved. One eastern firm has been using a Gramm truck in this work for several months and reports that the vehicle is accomplishing the same results as five two-horse teams formerly produced. The Gramm not only carries much more material than a horse drawn wagon, but consumes less time in transportation and further demonstrates its economy by eliminating a large percentage of the necessary labor."

FEDERAL AIDS SHIPPING.

Replaces Four Horses at Substantial Saving, Although Service Is Very Intermittent.

The Leyland Steamship Line, with headquarters at New Orleans, La., recently purchased a Federal truck, made by the Federal Motor Truck Company, Detroit, which displaced four horses. This company owns a number of wharves in New Orleans and must transport unloading skids and cranes from one quay to another to meet every inbound steamer. Heretofore, it was necessary to keep two two-horse teams in service, one working days and the other nights, in order that they might be ready at a moment's notice to remove tools and equipment from one ship to another.

This system was found to be expensive and the officials of the company decided that a substantial saving could be made by replacing the horses with a motor truck. The teams, although travelling but a short distance, were compelled to stand in the sun, rain and cold, awaiting orders. The elements have no effect on the Federal truck, and it is always in readiness to respond to a call from any dock. The gasoline consumption is small and the truck does the work much faster and covers more ground than formerly was true with horses.

BUFFALO'S FIRST TRUCK SHOW.

More Than a Score of Makes Shown at Exhibition Productive of Numerous Sales.

The show of service vehicles held at the Auditorium, Buffalo, N. Y., from March 12 to 15 inclusive, was the first exhibition of the kind ever made in that city, for in previous years they had been exhibited with pleasure cars. The Buffalo Automobile Dealers' Association decided to have the show for four days only and the show committee realized that a week would not have been too long a period, for the interest manifested was surprising and the promotive results were in every way satisfactory.

In all more than a score of different makes of machines were shown, there being close to 100 vehicles in the exhibition. In addition there was a very large motorcycle section and a considerable number of exhibitors displayed accessories and supplies.

WOULD HEAVILY TAX MOTOR TRUCKS.

Decided Opposition Develops Against Passage of Bills Now Before New York Legislature.

A determined effort has been made by the Motor Truck Club of New York City, and differing interests, either from the viewpoint of the industry and trade or from that of the owners and users, to oppose the legislation now pending before the New York legislature. The bills proposed are objected to on many grounds, one of which is that motor vehicles used for business purposes should not be subjected to additional tax, and another is that the control of drivers is not reasonable or logical. It is maintained that the application of the law rests with the courts, and individual interpretations of a bill are no criterion by which to judge its results; that to tax machines for the use of the highways is vicious class legislation, and that the requirements as to drivers are such as will cause inconvenience and in many instances hardship for business men.

The belief is that it will require careful and persistent endeavor to frame a bill that will differentiate the classes using motor vehicles and properly protect the interests of all the people. The proposed law is regarded as impractical and of such a character as would seriously affect all owners of service machines and discourage the business development that might be possible with their logical and rational use.

PORTABLE WIRELESS STATION.

New Type of Motor Vehicle Being Demonstrated to Government Officials.

A new portable type of complete wireless telegraph station has been exhibited recently to the government officials at Washington, D. C. The outfit, which includes two telescopic towers, is carried on a large automobile truck, and the two towers can be raised to an altitude of 200 feet by the same motor which propels the vehicle.

The instruments and generating apparatus are located in one of the rooms into which the body of the truck is divided. This room is also used by the operator in the sending and receiving of messages. The equipment includes a searchlight which, if necessary, can be hoisted and operated from the top of either of the 200-foot towers. At night illumination is supplied by a small electric plant operated by the truck motor.

The John Bell Company, a builders' supply firm in New York City, has placed an order for five Garford motor trucks of six tons capacity each, made by the Garford Company, Elyria, O. This firm bought a Garford machine about a year ago and the development of the Bronx borough, with its large building operations, has resulted in greatly increased business for the Bell company, which necessitated this enlarged equipment.

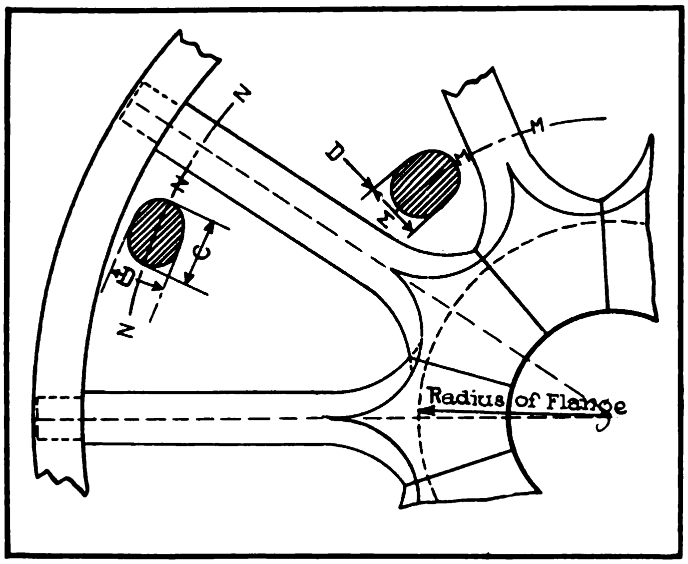
A handsome motor hearse built by the Peerless Motor Car Company, Cleveland, O., and displayed at the Chicago truck show has been purchased by the Newberry Auto Livery Company, Chicago, for use in conjunction with its 21 Peerless touring cars for funerals.

MOTOR TRUCK WHEEL CONSTRUCTION.

With No Standards for Dimensions or Stock, Designs Are Based Usually on Individual Experience or General Knowledge—Some Methods of Estimating Strength and Results From Laboratory Tests.

FOR several years the attention of manufacturers of automobile vehicles, both in this country and abroad, has been directed toward the service to be obtained from different types of wheels. The subject is not new, but the changed requirements have impelled careful study and investigation with a view of determining what would be the most enduring in the works for which vehicles may be used. For a very long period, in fact for centuries, wood was the material utilized, because of the cheapness and ease of working, and from the fact that with animal vehicles it was not subjected to great stresses.

With the construction of wagons and carriages dimensions were made without engineering knowledge, but generally were what in the judgment of the builder would serve the purpose. The staggered spoke type was adopted because of its assumed greater



Comparative Proportions of a Well Designed Automobile Wheel.

strength. Wheels were dished to resist the strain of turning and to bring the line of support more nearly vertical when the vehicle was standing or moving on an inclined surface.

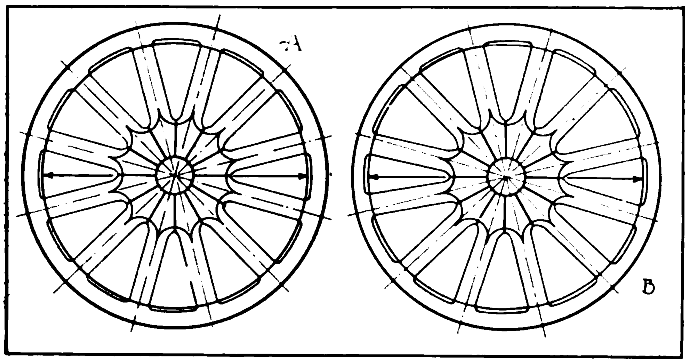
There are today no recognized standards for the construction of wheels save the felloe and rim dimensions adopted by the Society of Automobile Engineers, and the standard grading rules for vehicle wheel hickory wood stock, which were agreed to at a conference held Dec. 28-30, 1908, by the authorized representatives of the United States forest service, the wheel manufacturers, spoke manufacturers, rim manufacturers and the National Hickory Association. These grading rules were based upon the strength of hickory stock as determined by the mechanical tests of the forest service of the United States government, made at the Perdue University timber testing station at Lafayette, Ind., through the co-operation of the National Hickory Association. These tests determined that red, or red and white mixed hickory of equal dry weight and having similar defects was of the same strength as white hickory, and should be graded according to its quality regardless of its color.

These grades are known as A, B, C, D and E, and after a series of suggestions, definitions were adopted and rules agreed upon for the selection of stock for spokes and rims. So far as is known these rules are observed by all dealers in wheel stock and by those manufacturing wheels, but there are no rules for grading stock for automobile wheels. It may be accepted as a fact that the strength of hickory can be based upon weight, all other conditions being equal. But with the greatest care in the grading of hickory it is practically impossible to absolutely determine strength. This was demonstrated in the tests made at Perdue University to secure data for the conference to which reference has been made, where it was found in a long column or compression test of 45 grade C white spokes, one inch size, that the maximum load sustained before failure was 4220 pounds and the minimum load 1720 pounds, a difference of 2500. It is not purposed to discuss quality of wood entering into wheel construction, but it will be assumed that stock is as nearly uniform as it can be selected with careful observance of the standards for grading.

It should be stated, however, that it is hardly possible to make exact comparisons between wheels of European and American manufacture, because there are no known standards abroad, and it is impossible to find there wood that will compare in quality with the hickory of this country. In England especially the wood that would be suited for wheels is not obtainable from native stock, and for that reason it may be said that wire and metal wheels are regarded with more favor than they are elsewhere and are more generally used. In continental Europe woods that are much more suited to wheel construction, and which have much greater enduring qualities, are obtainable, this being especially true of France and Germany.

The building of wheels for animal drawn vehicles was generally by a "rule 'o thumb" and while every manufacturer probably will make recommendation as to dimensions that would give a reasonable or perhaps an entire satisfaction in service, it is extremely improbable that there would be agreement as to dimensions. There are, however, makers who have very carefully determined stresses and strains that must be endured by wheels and in constructions that are produced to meet with specified requirements the strength is sufficient and the stock is as uniform as it

is possible to select it. Some of the makers of the best wheels, which are built for the manufacturers of high class automobile vehicles, make the statement



Well Built Wheels: A, Felloe Joints Correct and Spokes Lined; B, Faulty Construction, with Joints and Spokes Not Correctly in Line, Weakening the Strength Materially.

that they seldom if ever determine the specifications of their products. The detail of the work is prepared by the builders of the machines and the wheels are turned out to the proportions wanted. These specifications vary materially. For instance, one of the makers of a three-ton truck specifies that the front wheels shall be 36 inches diameter with a 2.25-inch spoke, and the rear wheels with a 3.5-inch spoke, the front wheel to be equipped with a single and the rear with a dual tire. For the same size vehicle orders have been received for a two-inch spoke for the front wheel with a four-inch tire, and rear wheel a 2.75-inch spoke with a four-inch dual tire.

These instances are cited to illustrate the variance of the requirements of the builders of motor wagons, and to make clear that it is not possible to regard the wheel equipment as being uniform or standard. It is not for the wheel makers to question the specifications sent to them. These are prepared very generally by the engineers of the automobile manufacturers, and occasionally by the engineers employed by the axle builders, but these are not based on standards as are estimates for metal construction. It is stated by men who may be regarded as authorities that the sizes and dimensions for carrying different weights appear to be the deductions or opinions of architects and engineering draftsmen, and that it would seem practically impossible to determine these dimensions accurately.

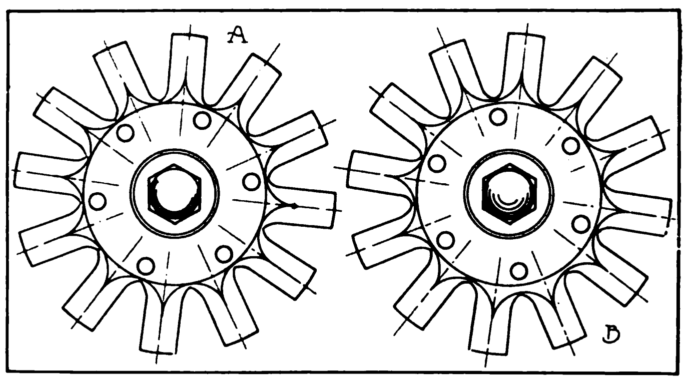
One manufacturer, in writing of the subject, makes the statement: "You will find that cars of from 1000 to 1500 pounds will use a 1.24 to 1.375-inch spoke, with a corresponding height of wheel and width of tire. A car weighing from 1500 to 2000 pounds will use a 1.5-inch, 1.675 to 1.75-inch spoke. Very few cars of this weight will use a spoke larger than 1.75 inches.

"We have had occasion to quote upon a great many different styles of truck wheels, and there is such a variation in them owing to the varying opinions of the manufacturers, that it would be absolutely impossible to give you standard dimensions per weight or per load carried."

It must not be assumed, however, that the wheel manufacturers are unmindful of wheel requirements. It is extremely probable that were they regarded as the authorities, with their experience and engineering data they would produce what would eventually be standards. As conditions now are they are compelled to accept any design submitted to them by the hundreds of engineers or engineering departments of automobile manufacturers. The wheels are guaranteed to endure under the service for which the vehicle is designed by the customers, which does not mean abnormal use or abuse by extreme overloads, and with firms that give these guarantees the wheels are fully checked as to strength under compression, dishing and torsion.

There is absolutely no standard for dimensions of spokes and felloes for the different diameter wheels for pleasure vehicles, and the dimensions of the spokes for service wagons are not standardized, but the felloes for such machines are standardized by the Society of Automobile Engineers. The dimensions for spokes are usually determined by the cross sectional area of the spoke and the weight of the vehicle on which the wheel is to be used. The dishing strength is figured from the hub flange diameter and the speed at which the vehicle is driven. There are principles recognized for pleasure vehicle wheel building that may be regarded as standard requirements, and in this respect there has been more attention given to such wheels than to those for service wagons. For instance, the angle of inclination allowed wheels when dishing is from 1.5 to two degrees from the full length of the spoke.

The weight of wood wheels for pleasure vehicles depends entirely upon the rim equipment, that is, the wood parts will remain practically the same, while the band is either heavier or lighter, according to the type applied. The sizes of wheels usually recommended for service wagons are often if not generally recommended by the tire companies, for these concerns are compelled to guarantee their tires for a specific mileage or service. For this reason the determination of sizes and proportions of wheels is frequently not left to the



Spoke Arches Correct and Incorrect: A, Equally Spaced from Outside Edge of Hub Flange; B, Unequally Spaced, a Guess Job and Poorly Done.

wheel makers, but the needs are established by those who cannot have the experience and the actual knowledge of working requirements.

In establishing load capacities it may be taken as a general rule that the rear wheels endure about 50 per cent. more weight or work than a front wheel. While this is, of course, a very broad statement, and should only be accepted as such, it will serve to illustrate the difference in the requirements and the strength ordinarily demanded. In some cases, according to the design of the vehicle, the rear wheels are made to carry a much greater percentage of the load than has been stated. The stresses upon a rear wheel in addition to those upon a front wheel are purely of those torsional strains given by the driving sprocket and the brake surface, to which must be added the side thrust when making turns and when the wheel is moving on a surface that is inclined. The front wheels, of course, have the same side strains and compression strains, and the driver lacks control or the machine becomes unmanageable for an instant it begins to skid. Assume that the inclination to the centre line of the road or the original direction of movement of the machine is 45 degrees and that the skid is in that direction. On most country roads the vehicle would not skid a much greater distance than four feet without striking soft earth or some other obstruction at the side of the roadway. Taking the weight of the machine, the speed, the angle, the coefficient of friction of rubber upon earth, and assuming that the car must be stopped within four feet will be the factors from which can be determined the side strain that must be withstood by the front and rear wheels. From this result may be figured the flange diameter that will give the cross sectional area in the miter surface to withstand the strain.

Summary of Tests of 12 Wheels for the Hayes Wheel Co., Jackson, Mich.

Testing Laboratory, Univ Mich

1911-July 19 C J [illegible] Engineer

same torsional strains that are due to revolution.

The overload that a well constructed wheel will endure is limited to the bearing area of the spoke upon the felloe. Taking the material from which the wheel is constructed, figuring the cross section area of the spoke and the strains a square inch, the amount of load that can be carried without failure can be fairly determined. To find strength or capacity of a wheel, the dish strength is determined from the speed at which the machine is to be driven and from the weight of the vehicle. In computing the dish for a pleasure vehicle wheel, for instance, the following illustration will serve:

It may be assumed that the machine is driven at a speed of 20 miles an hour on a country road that is comparatively smooth in the centre. Because the

The compression strains are figured as above stated, according to the cross sectional area or the bearing surface of the spoke upon the felloe. The construction for the best or greatest strength is a matter that may be stated in the following manner: The material of which the wheel is constructed must be absolutely dry, so that when it is assembled and the compression placed upon the miter circles by the band or rim, there will be no lessening of size. It might be well to state that there has been no standardization of the hub flanges used for pleasure cars or service wagons.

The emphasis that has been made of dry stock will be the better understood when it is realized that practically the entire strength of the wheel depends upon the tire or rim that encompasses it and binds it together. Wood as it is seasoned will lessen in every

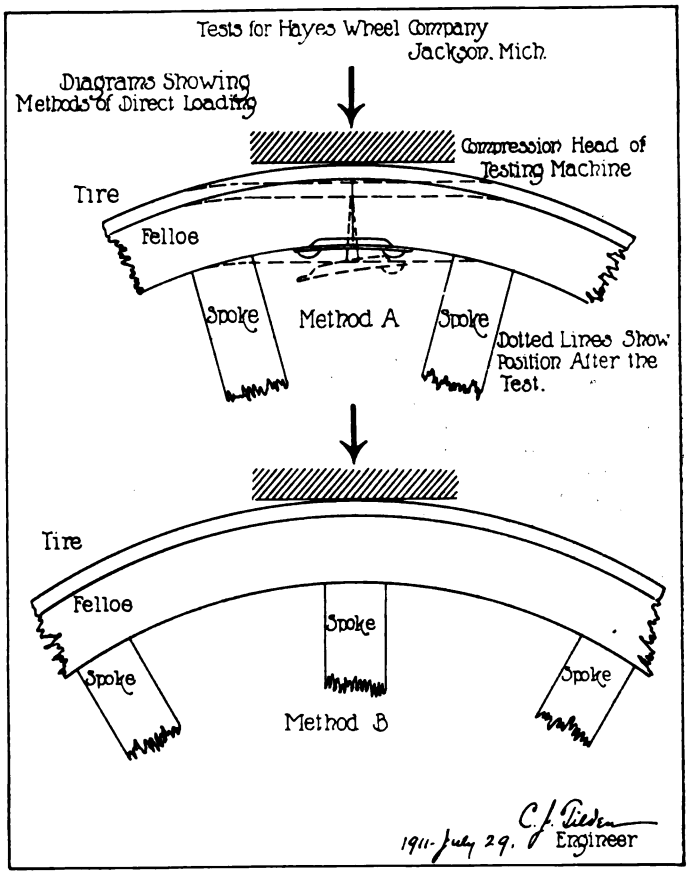
dimension, and it will shrink until all moisture has been dissipated. Seasoning or drying is best done in the open air and finished in kilns or ovens, where heated air is circulated about the lumber. Heating wood will reduce it to the smallest dimensions, and it will increase slightly when cooled and will expand to the maximum by saturation in water. Alternate wetting and drying will cause rapid deterioration of timber, but kept constantly dry or wet it will endure for an almost interminable length of time. Authorities on wood and wood working maintain that the American method of kiln drying lumber affords the best and most certain character of material, and that when built properly with reference to engineering principles there will be a minimum of changes from expansion and contraction.

Wood will contract and expand unequally, that is, different pieces will differ so far as absorption of moisture is concerned, and no matter what care is taken it is impossible to select stock that will be uniform in its changes. To secure material that will be as nearly equal as is practicable the grading rules have been adopted and weight accepted as a standard of strength. When the wheel is built the strength of the structure to resist twisting strains or side thrust depends upon the proportion of the spoke in the hub or between the hub flanges, and upon the area of the spoke cross section to carry the load. But the resistance to compression is proportional to the maintenance of the relation of the spoke and the felloe. Thus the tire or rim should bind the wheel so that it will always hold it securely, no matter what the climatic or atmospheric conditions, and the wood should be preserved so far as is possible against influences that will cause extremes of expansion or contraction.

When rear wheels are constructed they are designed for the attachment of brake drums, and these may be incorporated with the inside hub flange, or drums may be attached by clamps to the spokes or bolted to the spokes. All three of these designs are used generally, but it is probable that the last named type is the most common. By many engineers this construction is regarded as the best, provided that the bolts are centred in embosses in the spokes and the embosses' cross sectional area is equal to the cross sectional area of the remainder of the spoke. The strength of the spoke is retained in this type and the additional lever arm from the bolt head to the centre of the wheel is much greater than with other designs.

Saturation of the pores of the wood with oil will protect it, but to coat it with a thoroughly good paint, and to renew the paint as often as it is necessary, is believed to be the best protection that can be given. As only the exposed portions of the wood can be painted after the wheel has been constructed it would seem that there should be extreme care taken by the makers to paint and in every way protect the ends of the spokes in contact with the hub box and the hub flanges, the ends of the spokes in the felloe and against the rim and the felloe where it is covered with joint plates and the rims. Where these parts are not proof against expansion and contraction they may eventually decay and become weaker, to say nothing of the greater variation of dimensions from moisture and drying.

In applying the rim the wood, assumedly containing but a very small percentage of water, will shrink with the increase of temperature, and the rim, if heated, will expand, so that with the cooling of both materials a considerable degree of compression exists equally at all points. It will be noted, however, that there is a difficulty in painting the outer periphery of the felloe in that a heated rim will have a more or less destructive effect upon the pigment, and unless a rim is sufficiently expanded it will not be possible to install it or secure the proper compression. But when a rim



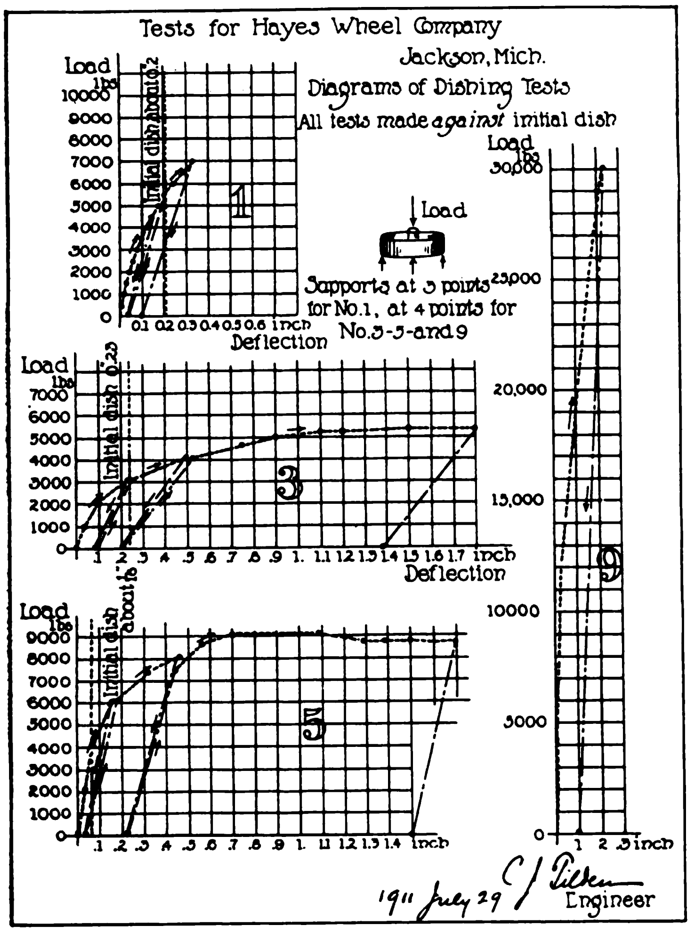
is once applied it is supposed to so bind the wheel that it will have its maximum strength when the wood has been shrunken, and will not cause distortion when the wood has been expanded by absorption. Extremes of heat will cause the wood to shrink and the metal to expand, and very low temperatures will correspondingly expand the wood and contract the rim. Heat is a factor of material importance, so far as the wood is concerned, because it causes shrinking, while moisture has the same effect with regard to expansion. The rim is not sufficiently changed by conditions ordinarily met with to justify consideration.

The shrinking and swelling of the wood from the hub to the face of the wheel as stated by a well known authority is summarized in this manner: If the wheel is of good, sound material, perfectly dried, swelling

caused by the climatic changes is not sufficient to deteriorate from the strength of the wheel. But this, of course, means that the wood shall be properly protected.

The small wheel is relatively stronger than the large against side thrust and torsional stresses because of the lessening of the lever arm, and that the members are relatively larger in proportion than those of the construction of increased diameter, but this strength is not a sufficient value to justify the rejection of the large wheel and its other manifestly good qualities.

While it is certain enough that the strength and endurance of wheels depends very largely upon the quality of the materials, there is no standard by which



a definite value may be established for varying sizes and constructions. The Hayes Wheel Company, Jackson, Mich., which has a very comprehensive engineering department, has supplemented the data obtained from the usual channels and from observation and experience, by a series of tests made at the testing laboratory of the University of Michigan. The charts included with the report of the tests made to the company are reproduced in connection with this article and the attention of the reader is directed to them.

Twelve wheels were tested, six for pleasure cars and six for service wagons, and these were subjected to dishing and compression tests to determine the elasticity of the different samples. It will be noted that there was some variance in the weights of wheels of the same type and sizes, and there was also slight difference in the diameters of the spokes and felloes. The greatest difference in the weight of pleasure car wheels of the same size was 1.25 pounds, and the variance in size of members or assembly was .05 inch. These wheels were supposedly pairs and one of each size was subjected to dishing and the other to compression stresses. The manner of applying the direct and the dishing loads are shown in the chart that gives the results, together with the points of measurement and the cross sections of spokes. It will be noted that two of the six truck wheels were tested for both dishing and compression.

The dishing tests were made by applying pressure to the hub of the wheel against the initial dish, the rim being supported at either three or four points, and the charts show the degree of deflection with varying loads, though not for all of the wheels. The chart denoting the results of the direct loading tests shows that two methods were used, these being designated as A and B. In test A the load was placed directly over the felloe joint and pressure was applied until bolts holding the joint plate failed and the rim was flattened, the felloe forced or broken down and the joint separated at the inner periphery. In this the pressure was applied between the spokes. In test B the pressure was applied directly above a spoke. It will be seen that this tested the weakest and the strongest parts of the wheels. It also will be seen that the smallest truck wheel was tested with a dishing pressure of 16,100 pounds and its mate was compressed with an external weight of 40,800 pounds. One of the next size was tested for dishing to 30,100 pounds and direct compression to 107,000 pounds, and its mate to 114,000 pounds direct compression. One of the largest wheels was tested to 48,300 dishing pressure and 133,000 direct compression, and its mate to 140,000 compression. The extreme figures for strength were 24 tons for dishing and 70 tons for compression.

These wheels were new and were tested at their best. It is probable that the strength would be somewhat reduced as they were used. It is also probable that were wood wheels in service in damp countries like England, or in the semi-tropics or tropics, there would be extremes of expansion and contraction that would eventually have deteriorating effects, so far as strength is concerned.

In the construction of wheels where the facilities are adequate a heating over is usually used to shrink the wood and heat the rim so that the assembly may be complete. As the wood is dry when the wheel is assembled, the best practise is to "prime" them with oil and lead so that they will not be susceptible to changes of temperature and atmosphere. Where wheels are cheaply made this provision may be omitted and the wood will swell and the grain raise, and perhaps other and more serious results follow. When wheels are so protected and are shipped by freight, for instance, they should be permitted to dry gradually and thoroughly before painting.

Municipal Service Equipment

COMPARATIVE COSTS IN SPOKANE.

Chief of Fire Department Presents Figures That Show Decided Economy.

Figures compiled by Chief A. L. Weeks of the Spokane fire department, Spokane, Wash., as to the comparative cost of automobile and horse drawn apparatus are taken by him to mean the gradual elimination of the horse as part of the equipment of the department. The city purchased two pieces of automobile apparatus in 1912 and will install two more during 1913, one of which will be made in the new workshop recently built and now being equipped at Spokane. The following figures from the annual report of the fire chief show the difference in cost of maintenance between motor and horse equipment:

Automobiles.	
Total maintenance, 1912, nine pieces, for gasoline, oils and repairs	$1,692.40
Average cost a machine a year	188.00
Total miles travelled	15,684
Average cost a mile	$.10
Horse Equipment.	
Total cost for 17 pieces, feed, shoeing and repairs	$7,339.19
Average cost a piece of apparatus	431.00
Total miles travelled	4,314
Cost a mile	$1.70

A combined hose wagon and pumping engine purchased recently from the Robinson Fire Apparatus Company at a cost of $8150 will replace four horses and two pieces of apparatus at the No. 10 station, and one driver will do the work that formerly required three men, a driver, stoker and engineer.

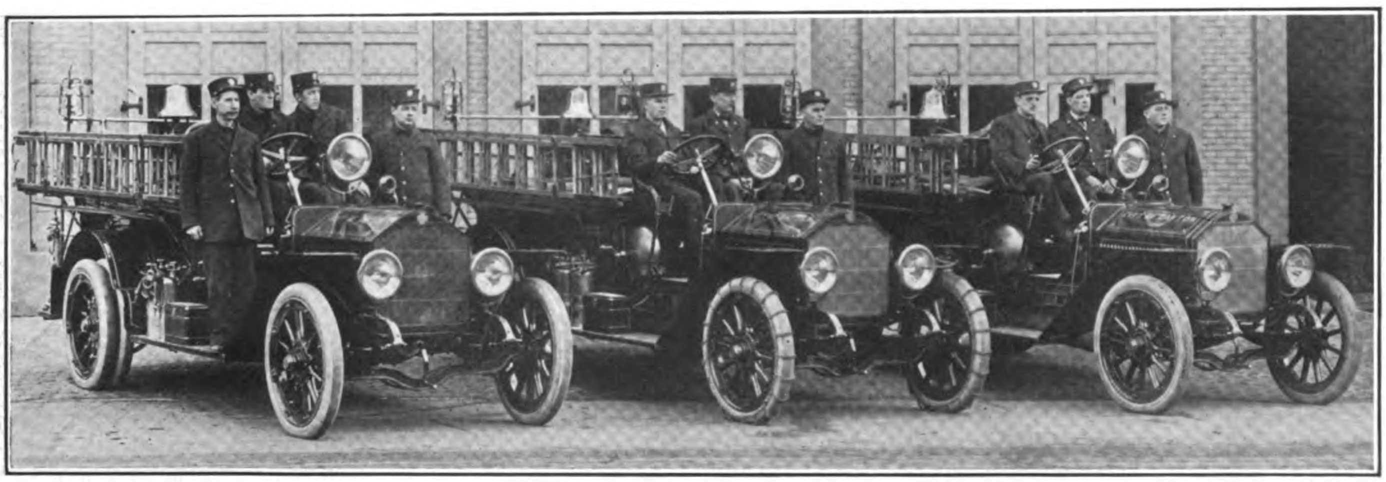
USE APLCO LIGHTING SYSTEM.

Three American-LaFrance Fire Cars in Dayton, O., Equipped with Home Product.

An accompanying illustration presents three of the American-LaFrance fire wagons in service with the department at Dayton, O., and as may be expected all three are equipped with the Aplco electric lighting system made by the Apple Electric Company of that city. In addition, these vehicles utilize the Dayton airless tires, made by the Dayton Airless Tire Company, also of that city.

The cars are the product of the American-LaFrance Fire Engine Company, Inc., of Elmira, N. Y., and are what is known as the type 10 combination chemical and hose wagon. The motor is a four-cylinder unit with bore of 5.5 inches and stroke of six, rated at 75 horsepower, brake test. The wheelbase is 140 inches, and the equipment, other than that mentioned above, includes a 40-gallon chemical tank, capacity for 1200 feet of 2.5-inch hose, 20-foot extension ladder, 12-foot roof ladder, hand extinguishers, axes and crowbars.

Of course, the photograph was taken before the recent Ohio floods, in which Dayton suffered so severely, but it serves to indicate the progressiveness that is manifested by the city in this department.



Three American-LaFrance Combination Fire Wagons in Dayton, O., Fitted with Aplco Lighting System and Dayton Airless Tires.

BUYING NO MORE HORSES.

Commissioner Johnson Announces Fire Department Will Be Completely Motorized in Five Years.

Fire Commissioner Johnson of the New York City fire department announces that no more horses will be purchased and that those now in service will be eliminated as fast as possible, automobile apparatus being substituted. He states that it will take about five years to completely motorize the department. There are now 1500 horses in use and 100 motors already have supplanted many of the animals. Before the end of the current year 100 more automobiles will be acquired. The equipment now consists of 850 pieces.

Horses die or go out of service in other ways at the rate of from 40 to 70 a year. As fast as they go they will be replaced by motors. The gradual conversion will cost about $2,500,000, and Commissioner Johnson says the money will be forthcoming at the required time. The attractive features of the change are found in that although the initial outlay is greater the ultimate cost is less, and the fire loss will be reduced because of the increased speed. Twelve tractors have replaced horses and 10 more will be delivered this year, while contracts for 28 others have been made.

FIRST IN THE UNITED STATES.

Niagara Engine Company in New London, Conn., Claims to Have the Original Motor Apparatus.

The recent 63d anniversary celebration of Niagara Engine Company No. 1, New London, Conn., was made particularly notable by the distribution of souvenirs commemorating what is claimed to be the first piece of motor apparatus ever put in service by an American fire department. This is the motor combination chemical and hose car, purchased of the American-LaFrance Fire Engine Company, Elmira, N. Y., and placed in active service Sept. 15, 1902. To each of the city officials a knife was given, bearing on one side a representation of the original automobile chemical, with the words, "First in the United States," and the date of its purchase. On the other side of the knife was a representation of the new triple combination pump, chemical and hose car, purchased the latter part of 1912 from the same company.

The old car does not look much like the apparatus in service today, but it is still doing duty, although it has never had a thorough overhauling. The machine is said to be the first piece of motor apparatus produced at the American-LaFrance factory, and is a steam propelled chemical with a Mason water-level type boiler, developing about 15 horsepower and giving about 20 miles an hour on level roads. Loaded the vehicle weighs 8000 pounds. Steam must be maintained under the boiler at all times and it takes about one minute to get up a running pressure. The members of the company, most of whom are skilled machinists, have had charge of the car, with the result that it has seen uninterrupted service and averaged about 75 runs a year since it was installed. The new machine is of 83 horsepower with capacity for 1000 feet of 2.5-inch hose and is equipped with a 40-gallon chemical tank.

It develops that the Niagara company has the oldest active fireman in the United States in George H. Powers, who has performed duty with the company for 53 years. He enjoys the unusual distinction of having worked at fires with the earliest hand drawn apparatus, then with the horse drawn vehicles and now with modern motor driven machines. It will be conceded that he is keenly aware of the progress made in fire fighting during the last half-century.

B. A. Gramm's Steel Dumping Truck in Service with the City of Seattle, Wash.

STEEL DUMPER FOR ROAD WORK.

City of Seattle, Wash., Acquires One of the New 3.5-Ton B. A. Gramm Trucks.

An accompanying illustration presents one of the new 3.5-ton B. A. Gramm trucks, made by the Gramm-Bernstein Company, Lima, O., in service with the street department in Seattle, Wash. It will be noted that the chassis is fitted with a rear dumping body and it is used in the hauling of sand, stone, etc., in road building work in the city and vicinity. It may be added that the dumping mechanism is operated by hand and the body is constructed of steel.

The 3.5-ton chassis is fitted with a four-cylinder motor, with cylinders cast in pairs, the bore being 4.5 inches and the stroke 5.5. The clutch is a multiple disc type and the transmission affords four forward

speeds and reverse. The gears are always in mesh, save when the machine is driving on the high speed, those on the main shaft being carried on roller bearings, and the dog clutches being secured by six splines instead of the usual keys. Another feature of the design is the use of the Gray & Davis electric lighting and starting system, the storage battery of which furnishes current for ignition for an Atwater Kent unisparker.

BUYS TEN MORE GARFORDS.

New York Police Department Finds Trial Machines Present Decided Saving for Year.

Police Commissioner Rhinelander Waldo of New York City, has awarded a contract to the R & L Company, eastern distributor for the Garford Company, Elyria, O., for 10 more Garford motor driven patrol wagons, to be delivered within 60 days. The police department already has three Garford machines and the big saving they have effected over the horse drawn wagons has convinced Commissioner Waldo that a complete motor equipment would be advantageous and economical for the city.

The following statistics, taken from the annual report of the police department for 1912, are extremely interesting and afford a reliable means of comparison between motors and horses:

Three motor patrol wagons were purchased and placed in service during 1912, replacing nine horse drawn patrol wagons and effecting a saving as shown below:

1911.		
Boarding 21 horses at $30 a month	$7,560.00	
Shoeing 21 horses at $5.50 a month	1,386.00	
Repairs to nine patrol wagons, $35 a year	315.00	
Repairs to nine sets of harness, $5 a year	45.00	
Eighteen patrolmen's salaries at $1400 a year	25,200.00	
Total		$34,506.00
1912.		
Automobiles kept in station house	......	
Tires, 48 at $37.05 each	$1,778.40	
Gasoline, oil and grease	595.00	
Nine patrolmen's salaries at $1400 a year	12,600.00	
Total		$14,973.40
Saving		$19,532.60

From this it will be seen that three motor wagons saved $19,532 in a year and no doubt when the additional 10 now ordered have been delivered and placed in service the resulting economy will be correspondingly greater.

NOTES FROM VARIOUS CITIES.

Fords in Police Department—Salt Lake City has placed in service two Ford cars, made by the Ford Motor Company, Detroit, for the use of the police department for making emergency calls. The plain clothes men will utilize the cars in their work, which will facilitate speed in getting to the scene of trouble when hurry calls are received.

Ahrens-Fox for Detroit—The Detroit fire department has put in service what is said to be the largest combination hose and chemical wagon ever built. The machine was made by the Ahrens-Fox Company, Cincinnati, O., and is equipped with a complete electric lighting plant, having two dynamos which are run by the gasoline engine. Three powerful searchlights are part of the apparatus, as is also a portable searchlight which will be used to light up ruins and smoky places. The wagon will carry 1500 feet of hose and a 50-gallon chemical tank.

Adams for Olean, N. Y.—A practical as well as an extremely striking motor chemical and hose wagon has been delivered to the fire department of Olean, N. Y., by the Adams Bros. Company, Findlay, O., maker of Adams trucks. The apparatus is mounted on a 1.5-ton chassis, and in addition to a 40-gallon chemical tank, is equipped with 200 feet of chemical hose, a 250-foot extension ladder, two fire axes, crow bars, lanterns, searchlight, etc.

Dubuque Motorizing Fire Department—The officials of Dubuque, Ia., have purchased a new triple combination chemical engine, hose wagon and fire engine of the Robinson Fire Apparatus Manufacturing Company, St. Louis, Mo., at a cost of $9000. The pump is capable of delivering more than 1000 gallons of water a minute. In the matter of furnishing fire protection to its citizens, Dubuque has rapidly come to the front among Iowa municipalities. On account of the hills and other natural conditions, automobile engines are said to be so much more suited to the needs of the fire department than the old horse drawn vehicles that many members of the city council are in favor of motorizing the entire equipment.

Lowell Adds Two Makes—The city of Lowell, Mass., recently put into service two pieces of motor fire apparatus. One is a Seagrave combination hose and chemical wagon, made by the Seagrave Company, Columbus, O. It has a six-cylinder, air-cooled motor and is electrically lighted throughout. The chemical tank has a capacity of 40 gallons and other equipment includes 200 feet chemical hose, 100 feet 2.5-inch fire hose and 36-foot ladder. The second machine is a Robinson, made by the Robinson Fire Apparatus Manufacturing Company, St. Louis, Mo. This is a powerful machine, capable of travelling 60 miles an hour and fully equipped and carrying 18 persons it weighs 10,450 pounds. It was the 172d Robinson car of its type constructed, but was the first installed in the East.

In the Market—The following cities are in the market for motor apparatus of various descriptions: Fond du Lac, Eau Claire, Janesville and La Crosse, Wis.; Traverse City and Kalamazoo, Mich.; Elkhart, Goshen, LaPorte and Michigan City, Ind.; Burlington, Davenport, Cedar Rapids, Des Moines, Fort Dodge and Marshalltown, Ia.; Oakland, Cal.; Westfield, Mass.; Berkeley, Cal.; Marshfield, Ore.; Springfield, Ill.; Pasadena, Cal.; Elmira, N. Y.

THE A B C OF MOTOR TRUCK IGNITION.

Part VIII---Outlining the Various Systems Utilized with the Commercial Gasoline Vehicle Their Components and Application in Practise---Explaining the Function of the Master Vibrator and Operation of Plug Transformers.

By C. P. Shattuck.

SYNCHRONIZATION is obtained by other units than the distributor, which method was discussed in the previous installment. It has been explained that with multiple cylinders it is important that the spark occur in each in proper order; that is, the compressed mixture should be ignited with each piston in exactly the same position relative to the crankshaft. While it would appear that a slight variance, a fraction of a second for example, would not affect the operation of the motor, this is not borne out in practise and especially is this found to be the case with high speed engines.

Fig. 36—K-W Master Vibrator.

When it is considered that some four-cylinder motors are capable of as high as 1700 revolutions a minute, it is easily seen that with one or more of its explosions occurring later than the others the impulses to the crankshaft are unevenly divided. Such a condition tends to destroy the balance of the engine, which at the best is not as perfect as with the six-cylinder unit. While vibration, especially at high speeds, with a four-cylinder motor is largely due to connecting rod angularity, which takes place twice each revolution, much of the unevenness may be caused by lack of uniformity in the ignition.

Value of Synchronization.

That the modern motor is more efficient than the earlier types is due in a great measure to the perfection of the magneto, which makes for synchronization of the spark mechanically. With the high-tension instrument the primary current is interrupted at the proper instant, and a distributor incorporated with it insures perfect timing of the spark.

There are, however, a large number of commercial vehicles in service which employ multiple-unit coils and utilize in connection with these a chemical source of current or a low-tension magneto. With the latter type the current is built up or converted into high-tension by the coils and synchronization is secured through the use of a master vibrator or by the distributor as previously explained. While a new high grade multiple-unit coil gives satisfactory results, practise bears out the statement that in time the vibrators lose their elasticity and that it is almost impossible to adjust the different units so that their speed will be the same. This lack of uniformity, together with the desire to economize room on the dash, has been responsible for the very general adoption of the magneto with a single coil either of the vibrating or non-vibrating type.

One of the most important functions of the master vibrator, in addition to synchronizing the spark, is that of regulating its size. With the ordinary type of multiple-unit coil in service the size of the spark will vary according to the adjustment and condition of the contact points. The results obtaining with a weak spark are well known by the operator. Not only is it difficult to start the motor, but its maximum efficiency is not developed because the charge is not ignited properly. And current may be wasted through incorrect adjustment of the contact points as well.

Function of Master Vibrator.

The master vibrator, as the name implies, replaces the vibrators of the coils, but the latter are essential to the operation of the system. Instead of four vibrators being utilized, but one is employed, the master unit, and as it performs the work of breaking the primary current at the proper instant it is obvious that synchronization must result, a condition that is not always possible when the other system is installed.

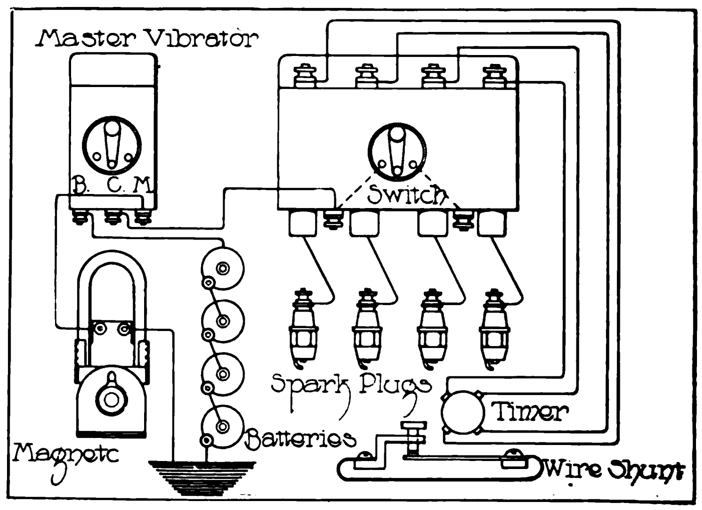


Fig. 37—Wiring Plan of K-W Master Vibrator with Magneto and Dry Cells, Also Showing Wire Shunt.

There are a number of master vibrators marketed and three conventional types are shown at Figs. 36,

39 and 43. Some idea of their compactness may be secured from the dimensions of the J & B instrument, made by the J & B Manufacturing Company, Pittsfield, Mass., and illustrated at Fig. 43, this being three inches wide and five high. Master vibrators are not always rectangular in form, as will be noted by the Briggs & Stratton, shown at Fig. 39. This member is circular and is 5.25 inches in height and 2.25 in diameter.

The J & B employs a triple-pole electro magnet, which the maker holds is more efficient than other forms in that it provides a greater surface for magnetic traction, as well as gives two independent magnetic circuits. It is also pointed out that in the construction opportunity for sticking vibrators is eliminated. The magnetic core is built up of laminated silico vanadium steel, which is held to be specially efficient for magnetic purposes where an alternating current is utilized.

Installing Master Vibrator.

A two-throw switch is utilized in connection with the master vibrator, as will be noted by referring to Fig. 36, which illustrates the K-W, made by the K-W Ignition Company, Cleveland, O., and while designed especially for model T Ford cars, is applicable to other multiple-cylinder motors. It may be employed with a set of dry cells or a storage battery, with a battery and a low-tension magneto, or with the magneto alone. This is demonstrated by the wiring plan presented at Fig. 37, which shows the K-W master vibrator utilized with a low-tension magneto by the K-W company with a set of dry cells as an auxiliary.

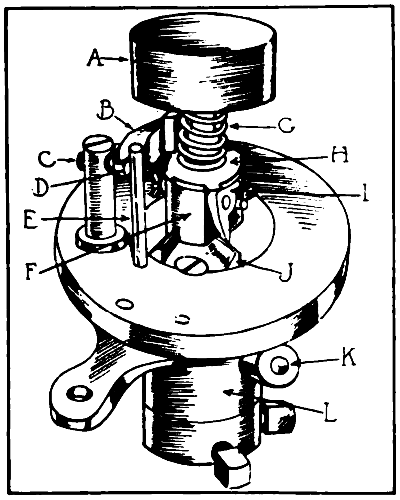

Fig. 38—Circuit Operating Mechanism of Rhoades' System.

It will be noted that the master vibrator is provided with three terminals and that these are marked B, C and M respectively. One wire from the dry cells is led to the post marked B (battery), and the other lead is grounded. The magneto is connected in circuit in a similar manner, one wire being grounded and the other connected to the terminal marked M (magneto).

Need of Wire Shunt.

As previously stated the master vibrator does not replace the usual coil. The latter is essential, but its vibrators must be short circuited or shunted as shown in the drawing at Fig. 37. This is accomplished by closing the circuit between the primary terminal post and the adjustable platinum contact screw by connecting these members with a piece of copper wire. While practically the same results may be obtained by screwing down the screw member until the contacting points are practically as one, the wiring method is recommended because there is apt to be more or less resistance when the platinum points are utilized, especially if they be pitted.

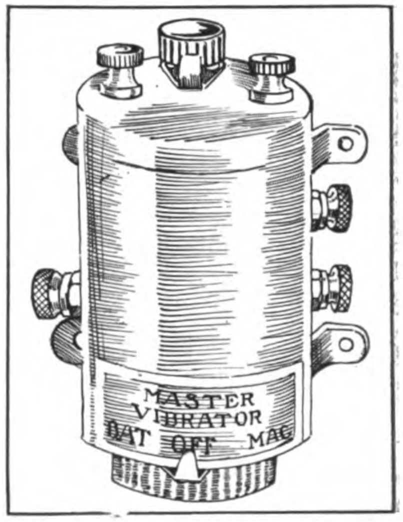

Fig. 39—Briggs & Stratton Master Vibrator.

The connections to the commutator and primary leads to the coil are not disturbed as the current is shunted to the master vibrator and the break in the primary circuit is made by the timer as usual. A wire is led from the battery terminal of regular coil to the post marked C (coil) on the master vibrator. The secondary leads are not changed in any manner, as it will be seen that the connections are the same as if the master vibrator were not used. The switch on the latter is employed to start and stop the motor and that on the regular coil is thrown to the lead connecting the coil with the master vibrator.

Wiring for Ford Cars.

When the master vibrator is fitted to Ford cars utilizing the flywheel type of magneto, the terminal M is connected with the magneto. A wire is led from the terminal on the coil switch marked "Magneto," to the post C on the master vibrator. Both the switches are consequently thrown to the "Magneto" position and that on the master vibrator is employed for starting and stopping. If dry cells or a storage battery be utilized as an auxiliary or for starting, one wire is connected to the B terminal on the master vibrator and the other grounded. A little study of the wiring plans presented herein should enable the reader to wire either system..

Rhoades' Unit Spark System.

The Rhoades' unit spark system, produced by the New York Coil Company, is of the distributor type and the breaking of the primary circuit is accomplished mechanically. The low-tension current is built

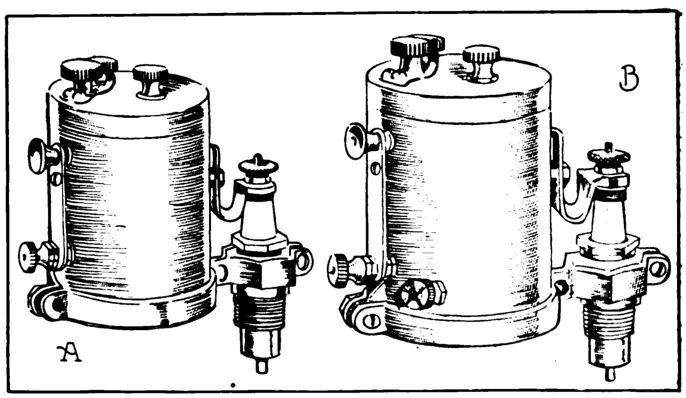

Fig. 40—Types of Plug Transformers: A, Briggs & Stratton Designed for Single-Cylinder Motors; B, Construction Adapted to Multi-Cylinder Engines.

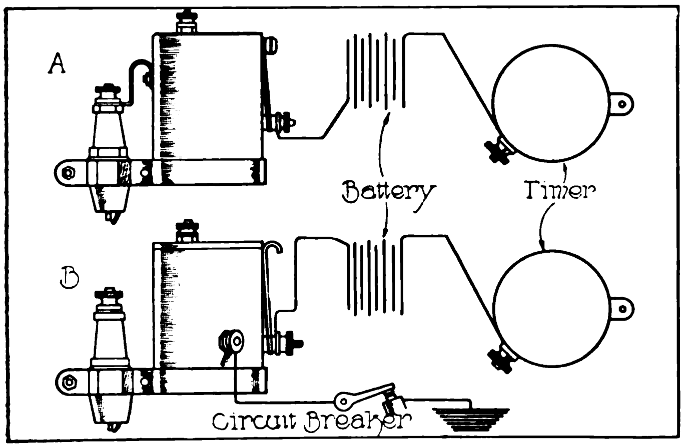

Fig. 41—Presenting Wiring Plans of Types A and B Briggs & Stratton Plug Transformers.

up by a non-vibrating coil and supplied to the various cylinders in proper order by a distributor which is incorporated with the circuit breaking mechanism. It is claimed that the system, current for which is supplied by a battery, will provide a very hot spark and that synchronization is secured through the construction of the circuit breaker.

The latter is illustrated at Fig. 38 with its cover removed and components lettered. The primary circuit is established and broken between the platinum point on the inner end of the adjusting screw C and the point B on the spring. Normally these members are separated. Their operation is as follows: The triangular pivot piece is tripped by the hardened projection J, and one, two, four or six of these are utilized, according to the number of cylinders. The upper end of I raises the disc H against the action of the coiled spring G, immediately under the distributing cylinder, and at the same time this disc is made to revolve by means of a pin. The disc H has projections, these corresponding to the number of cylinders, and the piece I allows it, under action of its spring, to snap back into the position from which it has been raised by I.

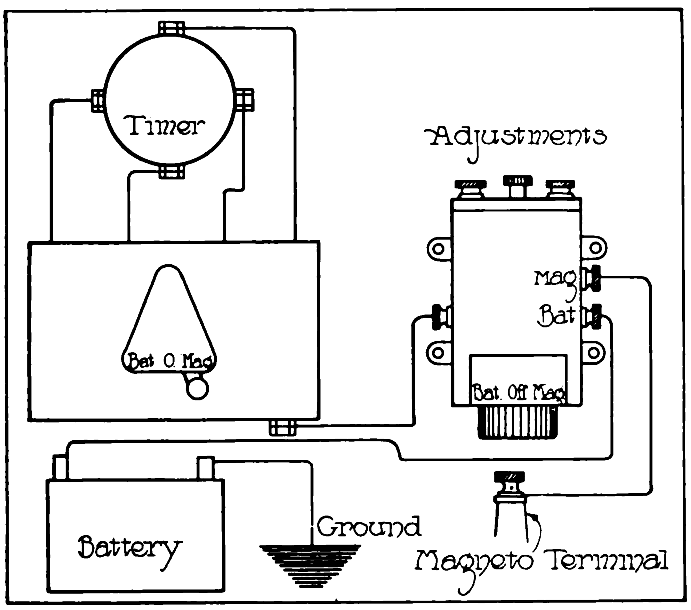

Fig. 42—Illustrating Connections of B. & S. Master Vibrator When Employed with Low-Tension Generator Utilized on Ford Cars, and with a Storage Battery.

As it snaps back one of these projections on the disc H engages on the slanting lip, which is formed on the flat lever D. To the latter is attached the contact spring B.

As the piece H snaps by the lip on B, it forces the contact members into engagement, establishing the primary circuit and keeping same closed during the transforming of the low-tension current into high by the coil. The upper portion A is the distributor, into which the secondary current is led through a pressed steel contact member, not shown in the drawing.

The combination unit is mounted on the timer shaft in the same manner as a timer or distributor and is provided with detachable secondary terminals, spring retained. The screw C is adjustable and by moving this member in or out the variance in voltage of the battery in service may be compensated for. The system is designed to be operated by a six-volt storage battery or a group of dry cells.

Plug Transformers.

There are several types of what are termed plug transformers, in which the vibrating coil, primary switch and secondary connection are a unit and the spark plug is secured to the construction. Two types of these are shown at Fig. 40, that at A being adapted to a single cylinder motor and more particularly designed for marine or stationary engines in that the switch is mounted on the transformer. It could be employed, however, with a single cylinder motor by installing a switch on the dash and carrying wires to the primary connections. That illustrated at B is suitable for service with any number of cylinders, but is provided with the same switch construction.

Fig. 43—J & B Master Vibrator.

The advantages claimed for the transformer, in addition to economy of current and a hot spark, are: Elimination of the usual secondary wires, and that only one wire is required, that running from the binding post at the base of the switch to the battery. The wiring plan is shown at Fig. 41 A.

The type B differs from that previously described only in the primary connection, which is brought out to a separate binding post instead of being grounded on the plug bracket. This adapts it to use with a ground circuit breaker and also on motors having more than one cylinder. The wiring plan is indicated at Fig. 41 B and it will be seen that one wire runs from the binding post of the switch to the battery. Another wire is connected between the circuit breaker and the other binding post on the transformer. The final connection is made between the remaining terminal on the battery and that on the timer. The same

wiring plan is utilized with either single or multiple cylinders, except that the timer occupies the place of the circuit breaker where more than one cylinder is employed. These types of transformers are illustrated to show the varying methods of obtaining a spark at the plugs.

Briggs & Stratton Vibrator.

At Fig. 39 is illustrated the master vibrator made by the Briggs & Stratton Company, Milwaukee, Wis., maker of the transformers mentioned above. It differs from those previously described in that it is circular and is very compact, being 4.25 inches high and 2.5 in diameter. It is secured to the dash by suitable brackets integral with it and the case is constructed of vulcanized fibre treated with a weather proof compound, and finished in black.

Among the advantages of the vibrator claimed are that pitting of the positive and negative platinum contact points is prevented, as the switch automatically reverses the direction of the current every time it is utilized, and that the motor cannot be started twice in succession on the same polarity of primary current. The adjustment of the vibrator is obtained by removing the cover, which is retained by two knurled screws, exposing a similar member. The connections and wiring plan are presented at Fig. 42, which illustrates that employed with Ford motor cars utilizing a low-tension magneto generating an alternating current.

As previously stated there are a number of transformers in which the spark plug is a part of the construction, but to describe these would be a repetition of those outlined in that the principle involved is similar.

(To Be Continued.)

Ed. Note—The next installment will deal with make and break ignition systems, also the low-tension magneto.

REDUCING DELIVERY COST.

St. Paul Concern Reduces Figure to 3.5 Cents a Package by Using KisselKar.

The Golden Rule department store of St. Paul, Minn., which is using four 1500-pound KisselKar trucks, made by the Kissel Motor Car Company, Hartford, Wis., in its delivery service, has issued a statement which shows that one of its machines is delivering at a cost a package of less than 3.5 cents. According to the record, the total cost for one year of the KisselKar in question was as follows: Gasoline, $283.44; lubricating oil, $49.20; tank recharges, $12; speedometer, chains, other articles and incidentals lost or broken, $33.90; tires, $474.48; tire and tube repairs, $91.65; driver's salary, $700; helper's salary, $260; total, $1804.67.

The number of packages delivered was 86,432, and an average of 49.5 miles was covered each day. When the truck was first put at work it handled 5428 packages a month. Every month has shown an increase until the number was 9109 packages in December, using the same amount of help and covering a slightly smaller area of territory than at first. The average daily delivery was 282.5 packages.

PACKARD HAULS MOTOR TRAIN.

Does the Work of Fifteen Pairs of Mules in Transporting Building Material.

Motor trucks are rapidly supplanting the mules in the mountains of North Carolina. F. L. Seely, who has charge of the construction work at Grove Park inn, on the slopes of Sunset mountain at Asheville, N. C., has adopted a Packard truck, made by the Packard Motor Car Company, Detroit, to do the hauling for that building.

The structure is being built of rough stones gathered on the mountain sides for several miles around. These are hauled on drags, sleds and wagons to the automobile road and there loaded on a motor train of 15 wagons and transported to the inn, three miles below, the Packard machine acting as an engine to the train. The truck does the work of 15 pairs of horses or mules and has been in this service for the past five months. It is working regularly from 7 in the morning until 6 at night and less than five hours have been lost during this period in making adjustments.

KNOX IS FARTHEST NORTH.

Two-Ton Vehicle Performs Satisfactory Service on Difficult Alaskan Trail.

What is claimed to have been the farthest north ever reached by any motor truck in the Western Hemisphere is the record accomplished recently by a Knox truck, made by the Knox Automobile Company, Springfield, Mass., and in the employ of the White Pass & Yukon Railroad Company in Alaska. The machine was put in operation on the Dawson-Overland trail in October, 1912, and in spite of the severe conditions along the trail, has made as high as 85 miles a day with a full two-ton load.

In the middle of December a load of Christmas freight was rushed from White Horse to Minto, a distance of 175 miles, in 2.5 days, a large part of the route having never been travelled by a motor vehicle before. Incidentally on this trip the machine covered one of the most hilly stretches of trail in the country in five hours, taking all the hills under its own power with full load of two tons, while a high powered touring car in attempting the same trail a week later required nine hours and was forced to make the hills with the assistance of block and tackle.

Farm Motors at St. Petersburg Show—It is announced that the committee of the forthcoming automobile show in St. Petersburg, Russia, in May, has decided to grant foreign exhibitors a premium of 1000 francs for each agricultural tractor installation—tractor and plow—or other agricultural machines shown.

New Commercial Car Accessories

O-Tak-A Tire Remover.

Removing large pneumatic tires is troublesome, especially when the rims have become rusted and the shoe is what is termed as frozen. Under the latter condition the casing is subjected to more or less stress in the attempt to break its contact with the rim and sometimes carelessness results in loosening the fabric in the side walls. The O-Tak-A tire remover was designed for this purpose and among its qualities is that of accomplishing the work without injuring the tire. It is adapted to clincher shoes by slipping a little attachment over the nose of the plunger, and is also applicable to quick detachable and demountable rims. When employed on clincher shoes it not only forces the bead away from the rim, but lifts the casing, permitting easy removal of the shoe. It is especially adapted to quick detachable rims in that actuating the lever makes it possible to displace easily the locking ring. A feature of the tool is that it locks automatically, allowing the operator to use both hands. The working parts do not come in contact with the paint of the wheel, acting only on the rim. The O-Tak-A comes in an aluminum or nickel finish and is marketed by J. W. Grumiaux, sales agent, Le Roy, N. Y.

J-M Fire Extinguisher.

The H. W. Johns-Manville Company, New York City, is marketing the J-M fire extinguisher, which comprises a compact metal tube filled with a dry powder guaranteed to put out any fire in its first stage, arising from gasoline, benzine, calcium chloride, etc., if utilized according to directions. The nature of the powder is such it will not injure the paint or upholstery of a car and it is also warranted not to freeze or cake within the container. It is constructed in a special size for automobiles and may be stored easily owing to its compactness.

Bay State Sticket Wrench.

The Bay State Sticket wrench, marketed by G. A. Cutter, sales agent, Taunton, Mass., comprises a double ended ratchet wrench, strapped to seven strong stamped steel sockets, strung on a square steel shank. One end of the wrench fits the shank and the other the sockets. The wrench also fits four sizes of nuts, and with the sockets 11 different sizes of nuts and cap screws. The reversible ratchet wrench is secured to the shank by a substantial leather strap and a washer prevents rattling. A 1.25-inch ball is fitted to one end of the shank, but is removable when the sockets are displaced. The other end of the shank has a ball stop and a spring ball for holding the socket in position. The wrench is adapted for a large variety of work and may be carried easily in the car. Extra sockets are supplied.

Reacto Electric Horn.

The Holtzer-Cabot Electric Company, Chicago and Boston, has perfected an electric horn which although moderately priced, is constructed of high grade material and with that care for which the products of this concern are noted. It is of the simple hammer blow type, a construction that secures a direct application of the power to the diaphragm and consequently instantaneous response. The heavy armature or hammer strikes the 5.5-inch diaphragm squarely and rebounds so quickly that rasping or discord in the sound is eliminated. The tone is clear and penetrating, but not harsh. One of the qualities of the horn is that it will respond to battery voltages 25 per cent. below normal and therefore does not require adjustment, although provision is made for altering the positions of the heavy platinum contact points. Sparking is prevented by the use of a well designed condenser. The binding posts are within the rear casing, and all carrying parts are insulated from the main structure. The horns are produced for any specified voltage from four to 125, thus adapting them for electric commercial vehicles, as well as gasoline cars. The standard finish is japan, baked on, with nickel throat, but it is also finished with polished brass throat, or full nickel or brass.

Thomas' Anti-Rim Rust Paint.

Rust is not only detrimental to the tires, but makes it difficult to remove them. The Anti-Rust Paint Company, Akron, O., is manufacturing Thomas' Anti-Rim Rust Paint, which is a compounded metallic liquid preparation, containing para rubber and graphite. It is utilized for painting the rims, preventing rust, and is also designed for painting the rim bolts and lugs of motor trucks. Another quality of the paint is that it may be employed between the leaves of springs. It is applied easily and is held to be very durable.

Vellumoid.

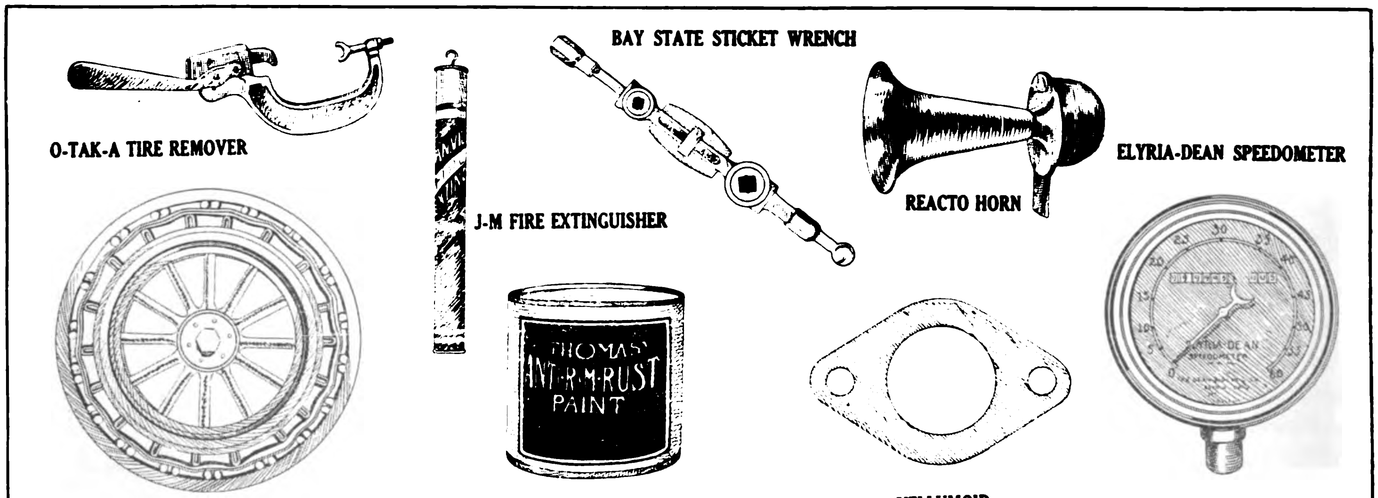
Vellumoid is a patented gasket material marketed by Charles D. Brown & Co., 49 Federal street, Boston. It is very tough, but pliable, and is impervious to the action of gasoline, kerosene, oils, water, etc. It is particularly adapted to motor cars for gaskets, either in hot or cold places, but is not suited to hot steam under pressure. It comes in sheets, or rolls, and is constructed in differing thicknesses to meet individual requirements.

Favary Tire.

The Favary tire, manufactured by the Favary Tire Company, Inc., 111 Broadway, New York City, is designed for commercial and pleasure vehicles, and resiliency is secured through pliable bands under tension. There are two of these rugged, water proof members, between which is placed a series of aluminum blocks secured by tubular rivets. The large heads of the latter rest upon the bands and their tubular section is opened on the aluminum blocks. The tread is detachable and the locking mechanism is positive. The principle involved in operation is as follows: Immediately under applied load the bands dip downward, while adjacent thereto there is an upward movement, due to the increased tension of the bands. It is held that the tension is quickly and easily adjusted to conform to the character of the roads and that resiliency is the chief feature of the tire.

Elyria-Dean Speedometer.

The Dean Electric Company, Elyria, O., is manufacturing the Elyria-Dean speedometer which is designed to withstand severe service and to record accurately the speed of motor vehicles. It differs from instruments working on the centrifugal principle in that four steel balls operate radially in grooves, so as to raise a cup shaped member and move the indicating hand over a long uniformly divided scale. This is accomplished without compensating springs or other modifying means being employed. The dial is finished in black, a reflection proof color, and the markings, letters, etc., are in white, making for easy readings. The total and trip members are actuated by separate mechanisms, serving as a double check on the mileage.



Some New Accessories, Including O-Tak-A Tire Remover, Reacto Electric Horn, Thomas' Anti-Rim Rust Paint, Vellumoid, Bay State Sticket Wrench, Etc.

FOREIGN TRUCK NOTES OF INTEREST

TO TEST FOUR-WHEEL DRIVE.

French War Office Desires to Adopt This Type of Motor Vehicle for Army Service.

The French war office has announced that it will hold trials of four-wheel drive vehicles and carriers, which should give interesting results. The trials will be held with the idea of making some very large government purchases during 1913, the French war office authorities having expressed their desire to adopt this type of machine for army service. The most noteworthy of the conditions are the following:

The vehicles must not weigh more than 5.5 tons, and must be able to carry a two-ton load; all parts must be at least 30 centimetres high above the ground; bodies must be provided with sides 60 centimetres high and must be capable of accommodating 12 men; a winding gear or capstan worked from the motor must be provided for winding 50 metres of cable; each wheel, as well as transmission, must be supplied with a brake; carburetors must be automatic and be able to use gasoline, benzol and alcohol.

ELECTRICS VS. HORSES.

Comparative Figures in Street Cleaning Work as Evolved by Department in Berlin.

At Berlin, Germany, the department in control of the city highways has placed in service 18 electrically driven washing machines, while 10 horse drawn pieces are still in use. During the last year six horse drawn vehicles were equipped with motors and six additional motor machines were purchased. The department has published the following figures bearing on the relative efficiency of motors and horses, the figures representing cost of operation for an eight-hour work day:

Electric Driven Machine.	
Driver's wage	$1.25
Electricity consumed, on the average 1.716 kilowatts an hour at 3.808 cents a kilowatt in eight hours	.52
Insurance of batteries against deterioration at $130.90 a year	.44
Repairs, figured on basis of past experience	.63
Amortization, figured at 15 per cent	1.49
More rapid consumption of rubber rollers owing to higher speed	.08
Total	$4.41

Horse Drawn Machine.	
Driver's wage	$1.12
Two horses, at $1.51 a horse	3.02
Repairs	.19
Amortization, figured at 10 per cent	.24
Total	$4.57

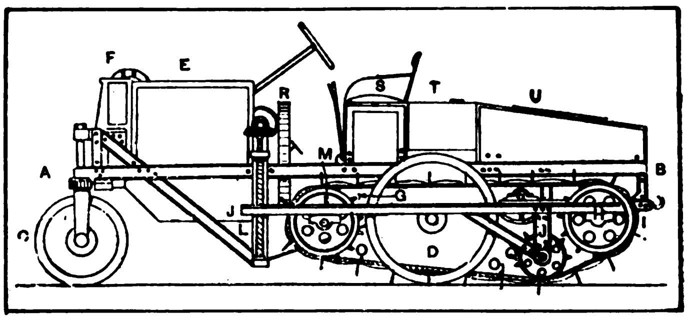
Commenting on these figures, the department points out that an electric machine cleans in an hour 6937 square yards of street surface, or in a day of eight hours, 55,496 square yards, at a cost, as shown, of $4.41, while a horse drawn machine cleans in the same time only 44,013 square yards at a cost of $4.57.

NEW THREE-WHEELED TRACTOR.

Lefebvre Product Recently Displayed at Agricultural Show in Paris, France.

Among the new agricultural motors revealed at the recent show in Paris, France, was the three-wheeled Lefebvre tractor designed for use in plowing or for hauling over soft ground. The accompanying rough sketch, which is reproduced from Motor Traction, a British magazine, indicates the construction and principle of operation, and it will be noted that the tractor is fitted with an endless chain arrangement carrying broad spike like blades which dig into the soil and provide additional traction. Of course, this arrangement is so contrived that it may be drawn up out of engagement when its service is not required.

The letters on the drawing have the following ref-



Sketch Presenting Principles of Construction and Operation of Lefebvre Agricultural Tractor.

erence: A B chassis, C steering wheel, D driving wheels, E motor (24-30 or 35-40 horsepower according to the type), F radiator, G transmission (affording four forward speeds ranging from nearly two miles to 5.5 miles an hour, and a reverse), H steel frame carrying two secondary shafts to which are fixed wheels I and J driving the endless chain. The frame pivots on the rear secondary shaft and the front portion is raised or lowered by the screw L, which is rotated by a bevel gear by means of a belt taken from the flywheel R.

When travelling on roads or in turning, the frame or chains are raised, and when working on the land the frame is lowered until the blades are sufficiently gripped in the soil to give the necessary adherence. M shows the position of a device for regulating the tension of the chain O, which is fitted with a chrome leather band, preventing it from coming into contact with the soil. The third wheel Q compels the blades to leave the soil almost vertically. T is the fuel tank and U the tool chest.

BELSIZE THREE-TON MODEL.

Type of Chassis Regarded by British Engineers as Possessing Particular Merit.

The Belsize Motors, Ltd., Manchester, England, is among the British constructors of commercial motor vehicles which have enjoyed wide recognition in Great Britain and its colonies. Many Belsize machines are being used by the government, particularly in the royal mail service, and these have given eminent satisfaction. The three-ton vehicle, shown herewith, is regarded by British engineers as possessing a number of features of merit.

The question of worm vs. chain drive is one that does not appear to have been solved definitely by a number of makers in Great Britain, and while this model is regularly supplied with the worm, an option of the chain is permitted. Of course, the body equipment is built to individual specifications, following the practise in vogue abroad.

Belsize Three-Ton Worm Driven Truck, Which Embodies Interesting Constructional Features.

Special attention is drawn by the maker to the deep radiator and the so-called Butler type of front axle. The latter differs from conventional practise in this country in that it is a straight forging. It appears to be made in two sections and the spring saddles are of separate construction, permitting easy removal and replacement in case of necessity.

Other features include the use of twin torque rods, locomotive type propeller shaft brake and a high pitched frame. The motor is a four-cylinder unit, of the T head type, with cylinders cast in pairs, the bore being 4.5 inches and the stroke five. Lubrication is by a gear driven pump. Ignition is by Bosch magneto. The clutch is a Hele-Shaw, and the transmission provides four speeds forward and reverse, with direct drive on the fourth. The wheels are of the artillery type, with 30 by four-inch solid tires in front and 34 by eight-inch dual members at the rear. The wheelbase is 138 inches.

HEAVY DUTY HALLEY TRUCK.

Interesting Six-Cylinder Machine Recently Introduced by Well Known Scotch Manufacturer.

One of the most interesting vehicles displayed at the recent show in Manchester, England, was the new Halley Colonial model, rated at six tons, made by Halley's Industrial Motors, Ltd., Yoker, Glasgow, Scotland. The machine is said to have been subjected to severe tests over all kinds of rocky, uneven and marshy land, carrying a maximum load of seven tons. As may be imagined, the construction is particularly heavy throughout, and it embodies a number of features that are of special interest.

In the first place, the motor is a six-cylinder unit, with bore of five inches and stroke of 5.5. The cylinders are cast separately with inlet and exhaust valves on opposite sides. The engine is said to have developed 75 horsepower on a brake test, and differs but slightly from that utilized in the Halley fire engines. The speed is controlled by a centrifugal type governor. Ignition is by Bosch high-tension magneto, with storage battery and coil as an auxiliary.

The clutch is a cone. The transmission gives four speeds forward and reverse, and the gears are in constant mesh, being brought into action through dog clutches. The differential is of the bevel pinion type and may be locked by a separate dog clutch to insure an even drive from both wheels on soft or slippery ground. Final drive is by side chains, and these with the differential shaft sprockets and all gearing are enclosed in oil tight cases. Exact alignment of the rear wheels is secured by strong radius rods, with a bevel and cross shaft compensating device to insure equal tension on the driving chains.

The driving wheels are five feet in diameter and 12 inches across the treads. It ought to be mentioned that both front and rear wheels are of the steel plate disc type. The rear members are provided with removable diagonal strips around the circumference to prevent slipping, and there are eight hand holes on the outside for riveting on these strips when necessary. The wheels revolve on a substantial nickel axle, with extra long bearings at the hubs, outside of which are mounted a pair of large winding drums, made to carry 150 feet of strong steel wire rope. These may be used for hauling purposes, but are specially intended to assist the vehicle in extricating itself from mudholes and the like, and the maker states that they are

capable of hoisting vertically a weight equal to that of the combined machine and load. The use of such large driving wheels has necessitated the introduction of a new reduction gear, which has been made the subject of a patent, and which is held to overcome the speed reduction difficulty.

The front wheels are three feet 10 inches in diameter and six inches across the plain treads. The front axle is of special construction, and being pivoted at the centre gives a three point suspension to the chassis. This is held to permit the vehicle to pass over obstacles 16 inches in height without any distortion of the frame. Above the axle is a strong built-up semi-elliptic spring, free to move radially on a central pivot, permitting the axle to have free vertical movement at either end, while its longitudinal position is maintained by a cast steel horn block bracket, in which the axle is free to move up or down.

FUEL IN SOUTH AFRICA.

Experiments With Motor Transportation Indicates Alcohol Must Be Used for Desired Success.

At a recent meeting of the North Charterland Exploration Company, Ltd., at London, the chairman, Sir H. F. Wilson, stated that the directors of the company felt recourse must be had in South Africa to motor trucks in order to reduce the time taken between Fort Jameson and the river in the transportation of cotton. The time now taken by wagons and carriers is from four to five weeks and unless this time could be reduced the company would find it necessary to secure a large number of teams and native carriers at exorbitant prices. Some experiments have been made with motor traction, the demonstrations proving that to enable it to become commercially practicable the fuel to be used must be alcohol, which must be distilled locally.

The company had, therefore, he stated, obtained from the administration of Northern Rhodesia permission to prepare and make use of denatured alcohol for transport purposes under certain necessary restrictions without payment of excise duty. It is proposed, in co-operation with the West Nyassaland Estates, Ltd., to establish a distillery plant at Fort Jameson to make alcohol for road motor and agricultural machines. This will be the first plant of its kind in South Africa and by its means regular motor transportation will be maintained in the dry season between Fort Jameson and Tete. The details are now under consideration.

GENERAL NEWS FROM ABROAD.

Motor Mail Service in India—A new motor mail service has been established in British India, operating between Trichinipoly and Puddukotta, a distance of about 33 miles. Four cars are utilized, each carrying a post box available to the public at the recognized stopping places.

Seeking Substitute Fuel—A special committee representing the Royal Automobile Club of Great Britain, the Automobile Association, the Commercial Motor Users' Association and the Society of Motor Manufacturers & Traders, has been appointed to investigate the subject of fuel. The outcome of the committee's deliberations thus far is a recommendation that further investigations be made into the matter of production of alternative fuels and particularly of benzol.

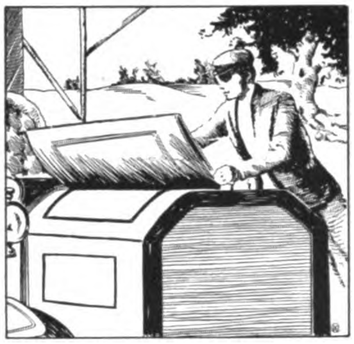
Producing Road Sweeper—One of the first motor road sweepers to be built for service in Great Britain has been produced by the Lacre Motor Car Company, Letchworth, England, for use in Glasgow, Scotland. The motor is an 18 horsepower two-cylinder unit of the firm's standard type, and means are provided for operating the revolving brush through the action of a dog clutch.

Motor Plowing Competition—A proposition is under way for the holding of a motor plowing competition in connection with the jubilee agricultural exhibitin at Konigsberg, Germany, as a part of the Prussian centenary fetes.

Office Car for Savings Bank—Gebruder Stoewer of Stettin, Germany, has just completed an office car for the Municipal Savings Bank in that city, which is intended for use in connecting the central headquarters with the several branches of the bank. It comprises a safe and shelves for arranging any documents and books that are to be transferred, and is fully protected against intrusion while en route.

Motor Traction in Java—According to the Bulletin Commercial of Brussels, Belgium, experiments made in the interior of Java with two motor trucks for transportation work on the tea plantations of the Preanger as far as Wijnkoops bay, have resulted to the entire satisfaction of the planters. A plan is now under way to increase the number of cars to five, and it is held to be probable that before long the service will be extended to a number of places now inaccessible to railroads.

New Zealand Dairy Farmers—At a recent meeting of New Zealand dairy farmers in Christchurch, an agreement was reached to adopt motor vehicles in place of horse wagons for carting milk and cream to the creamery. The Central Dairy Company reported that the annual expense of transporting cream and butter by rail had been £1942, while the use of horses in bringing milk and cream to the plant had cost £897, not counting the item of £144 for feed and shoeing. It was the opinion of this concern that the motor vehicles not only would cost less, but would bring about a decided saving through their greater speed.



HINTS·FOR·PROPER MAINTENANCE

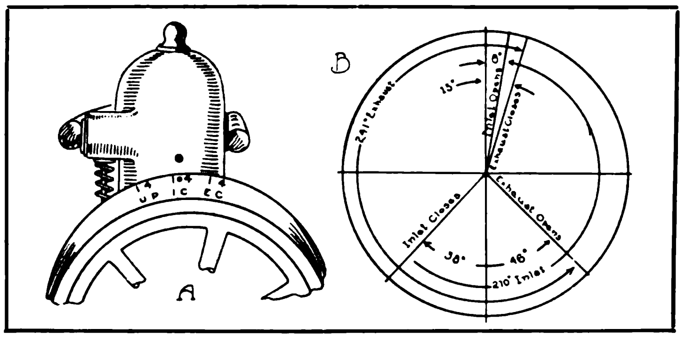
A Department for the Owner, Driver and Repairman.

TIMING WITH UNMARKED GEARS.

The correct replacement of the camshafts in the overhaul of a motor is a simple matter when the gears are marked and the majority of motors come from the factory with prick punches on the teeth of the gears. If they do not exist and the camshafts are removed without marking or the gears become broken in service it will be necessary to retime the valves and for this work the timing will have to be secured from the factory or agent.

In replacing the camshaft the gears should be so remeshed that the cam actuating the intake valve of the first cylinder begins to move and lift the valve when the flywheel is rotated a certain number of degrees.

Assume that the motor is a four-cylinder unit and



Valve Timing with Unmarked Flywheel: A, Showing How Cylinder May Be Prick Punched and Flywheel Marked After Degrees Are Laid Out by Diagram Indicated at B.

the valve timing is as follows: Intake opens at eight degrees past upper dead centre and closes when it is 38 degrees past lower dead centre. The exhaust opens 46 degrees before the lower dead centre and closes 15 degrees past upper dead centre. This indicates that the exhaust opens early and closes late and that the inlet opens and closes late.

Laying Out Degrees.

Assume that the flywheel is 17 inches in diameter and that the valve openings are not marked upon its periphery. It is a simple matter to lay out the degrees or mark it by inches. The figures will be as follows: Inlet opens late 1.1875 inches, closes late 5.65625. Exhaust valve opens early 6.84375 and closes late 2.234375. Top and lower dead centres are essential and these may be secured by turning the flywheel until the pistons of the first and fourth cylinders are at the top. Mark the flywheel for these positions and make a prick punch on the rear cylinder as indicated at A in the accompanying illustration.

Next measure off 1.1875 inches on the periphery of the flywheel to the right as the inlet valve opens late. Turn the flywheel to the left until the mark registers with that on the cylinder and replace camshaft, meshing gears in such manner that the inlet valve of the first cylinder will begin to lift. After fitting the camshaft rotate the flywheel in the direction opposite to which it travels and then move to the left to make sure that the inlet valve of the first cylinder starts to lift when the mark on the flywheel coincides with that on the cylinder.

Marking the Flywheel.

The timing may be checked up for each valve to make sure the setting is correct by measuring off the distances on the flywheel and marking these with a prick punch. Assuming that the firing order of the motor is 1, 3, 4, 2, the marks on the flywheel will be as follows:

1-4, I-O	inlet valves	1 or 4 open
1-4, I-C	inlet valves	1 or 4 close
1-4, E-O	exhaust valves	1 or 4 open
1-4, E-C	exhaust valves	1 or 4 close
2-3, I-O	inlet valves	2 or 3 open
2-3, I-C	inlet valves	2 or 3 close
2-3, E-O	exhaust valves	2 or 3 open
2-3, E-C	exhaust valves	2 or 3 close

The setting of each valve may be tested by rotating the flywheel in the normal direction until the mark thereon for the inlet valve of the first cylinder registers with that on the cylinder and the balance of the valves check in a similar manner. If the valve mechanism is adjustable, it can be changed to correspond with the marks on the flywheel.

CARE AND REPAIR OF BRAKES.

With large diameter drums and ample face, brakes give maximum efficiency and aside from an occasional adjustment do not cause trouble. There are, however, a large number of converted pleasure cars utilized for commercial purposes and the brakes and linings will require attention from time to time. If the driver is familiar with the principle of brake construction he should be able to make minor repairs as well as adjustments.

Brakes may be divided into two classes, the exter-

nal contracting and internal expanding, although these forms may be applied in a different manner; that is to say, the brake drum may be so constructed as to enclose the contracting band. The principle, however, is similar to the external design.

While it would appear that it is a simple matter to adjust brakes of either type when they do not grip properly, one might so alter the contracting or expanding mechanism that the desired result would be attained, but the brakes would drag. Friction should not exist between the linings and drums because undue wear of the former results, to say nothing of wasted power.

Bands Should Be Clean.

When brakes do not hold it does not necessarily mean that the bands need readjusting. It is possible that the friction surfaces may be covered with oil or grease, a condition that is frequently taken as an indication that new linings are required, especially after the limit in adjustment has been reached. Before assuming that new linings are needed remove the wheels and examine the linings to note if they are impregnated with lubricant. If so, clean them with gasoline and kerosene. It may be possible that the presence of the grease is due to lubricant working out from the differential into the brake drums. Sometimes this is caused by wear of the felt washers, which should be replaced with new members.

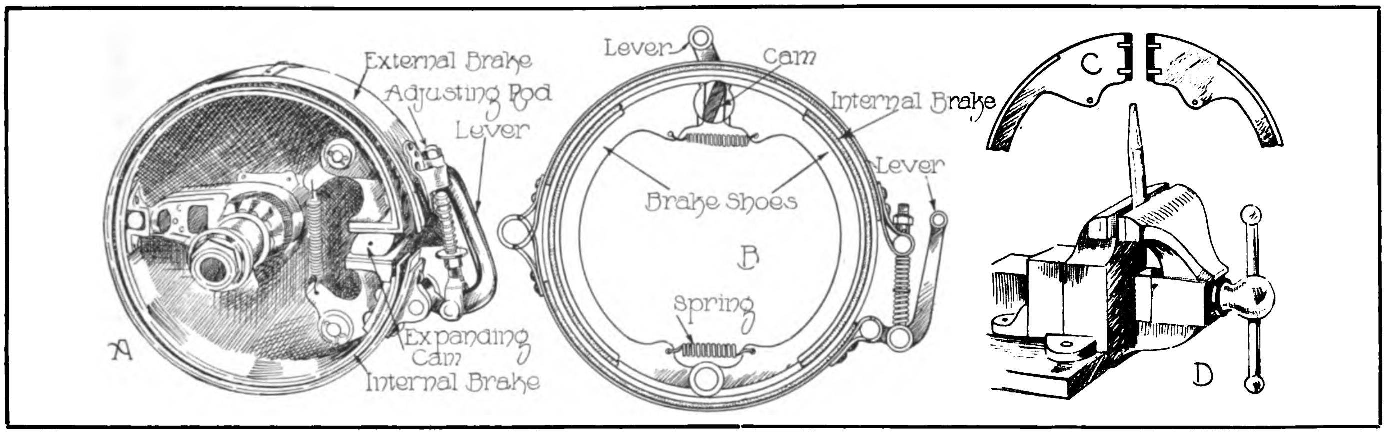
An accompanying illustration shows two types of brakes, that at A being conventional in design. As the components are clearly marked the reader should be able to understand their operation. It will be seen that the outer or external band is of the contracting type, is actuated by a lever and toggle joint arrangement and that means are provided for lengthening or shortening the rod opening and closing the brake proper. By shortening the area of the gripping band is restricted.

Repairing Worn Brakes.

The internal expanding brakes are operated by a double cam and as these are generally employed for the emergency brakes, there is little wear of the expanding mechanism. Where they are utilized for service members, however, the cams will wear in time. When badly worn it may be necessary to fit new parts, but a repair may be effected as outlined at C, this consisting of building up the face members. In making this repair care should be exercised not to increase the normal diameter of the shoe and due allowance should be made for the brake linings, else the brakes will drag and heat.

In relining brakes the first step is to ascertain the original thickness of the lining and the material used. The same width should be employed and the drum measured to obtain the correct length. This is a case of mathematics, or the drum may be measured with a string. Brake linings come in varying thicknesses, ranging from .125 to .25 inch. There are several excellent materials for this work and a list will be found in the Classified Buyers' Guide, elsewhere in this issue.

Removing the shoes is not a difficult operation, but before attempting to displace the rivets securing the lining to the shoes, the latter should be thoroughly washed in gasoline. Some employ a torch to burn off the grease, but the writer prefers the washing process. The shoe is next clamped in the vise and the peined-over rivets cut off with a sharp cold chisel and a hammer. The rivets can then be driven out easily with a punch.



Illustrating Types of Brakes: A, Showing Components of External Contracting and Internal Expanding Design; B, Those Utilized on a Pleasure Vehicle; C, Method of Repairing Worn Faces with Metal Strips Retained by Machine Screws; D, Depicting Use of Punch When Riveting New Linings to Shoes.

Relining Brakes.

Next clean the shoe and secure one end of the new lining to it by clamping the parts in the vise, taking care that the facing is even or flush with the edge of the shoe. In attempting his first relining the novice is apt to fit it unevenly, but by observing caution the band should be free from wrinkles and true.

With the shoe and lining held securely in the vise the drill is run through the rivet hole in the shoe and lining and the latter afterward countersunk so that the head will be well below the contacting surface of the lining when the work is completed. After drilling a number of holes and inserting the copper rivets the shoe is removed from the vise and a punch gripped in the jaws as shown in the drawing. The shoe is then held on the punch so that the head of the rivet is in contact with the top of the punch. The small end of the rivet may then be peined over easily. The rivets should be about as long as the total thickness of the

lining and shoe, which will be plenty long enough, as it must be borne in mind that the lining is countersunk.

In reassembling the brakes all springs should be tested to note if they have the correct tension and are holding the parts properly. When the springs have become stretched or have lost their elasticity the brakes may drag even when properly adjusted. After replacing the wheel and making the final adjustment, rotate the wheels and note if the brakes drag. A simple method is to place the hand on the brake drum after a short run to learn if the drums are unduly warm. If so the adjustments should be altered, as this is a good indication that there is undue friction.

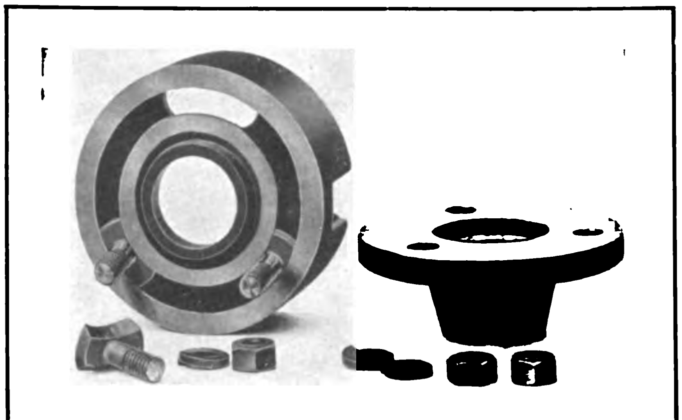


Fig. 1—Showing the Components of Bosch Coupling, Including Cone Member, Flange, Crossbar and Bolts.

As the work of relining the shoes will necessitate the removal of the hub caps, these members should be cleaned and repacked with fresh grease. In locking wheels do not forget to replace all the cotter pins.

BOSCH ADJUSTABLE COUPLING.

Announcement is made by the Bosch Magneto Company, New York City, of a new adjustable flexible coupling adaptable for driving a magneto, pump, etc., where the driving and driven members are out of alignment. The device, which is shown at Fig. 2, has another advantage in that a magneto may be displaced without disturbing the timing or any part of the driving mechanism.

The Bosch coupling comprises a cone shaped piece of steel attached to the armature shaft and terminating in a ring having diametrical fibre lined slots. To the driving shaft is secured a flange that carries a flat crossbar consisting of a large number of fine spring steel leaves or plates. The crossbar fits in the slots or recesses of the cone shaped member, as is shown at Fig. 1.

The laminated crossbar has a marked spring action and permits the two members of the coupling to have a slight relative torsional movement, which is ample to absorb the shock of varying resistance to the rotation of the magneto armature. The spring crossbar also has a slight bending or twisting movement sideways, permitting the two shafts to be slightly out of line. With a rigid coupling the driving and driven shafts must be aligned, and the shock created by the magnetic resistance is transmitted to the driving gears, producing noise. Noisy action is eliminated in the Bosch spring crossbar and ring by lining the cavities with fibre, which in addition, obviates the necessity for lubrication of the working parts.

The cone shaped member of the coupling is made with proper tapers for various types of Bosch magnetos, a recess being provided for the armature nut. This section is keyed to the armature shaft, while the other member of the coupling may be attached to the driving shaft by a key or the bolt which accompanies the coupling.

Where the adjustable flexible coupling differs particularly from the usual flexible coupling is in the construction of the cone shaped member. In the adjustable type this is made in two parts instead of one, the portion engaging the driving member having a circular groove carrying three bolts with tapered heads, as is shown at Fig. 1, which depicts the disassembled coupling.

The portion which is actually secured to the armature shaft is an ordinary flange having three holes in which the taper headed bolts register. When the nuts on these bolts are set up tight there can be no relative motion between the two portions, due to the binding effect of the taper; so that the sections become as one. Upon loosening the nuts, the magneto armature, together with its portion of the coupling, can be rotated through a complete circle.

A vernier engraved on the stationary portion permits accurate regulation to any degree and on this account the magneto may be mounted on the motor without reference to the timing and the armature set in any position after the entire apparatus is fixed. The construction permits of tests being made to secure the best results from timing without changing keyways, cotter pins, etc.; or in other words, the position of the armature may be altered slightly after installing the magneto, a condition not possible with rigid couplings without attention and considerable labor.

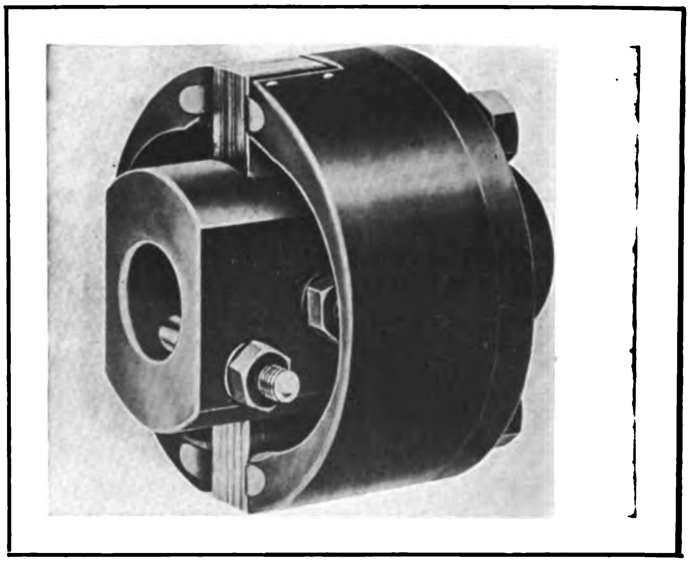

Fig. 2—Bosch Adjustable Flexible Coupling Permitting Driven Unit to Operate Out of Centre or Line, and to Change Timing Without Removing Magneto.

CORRESPONDENCE WITH THE READER.

Timing Splitdorf Magneto.

(29)—Would like information concerning the timing of a Splitdorf magneto and how it may be changed from a right to left hand drive or vice versa. Am installing the magneto on a converted pleasure car which I am using in my business.

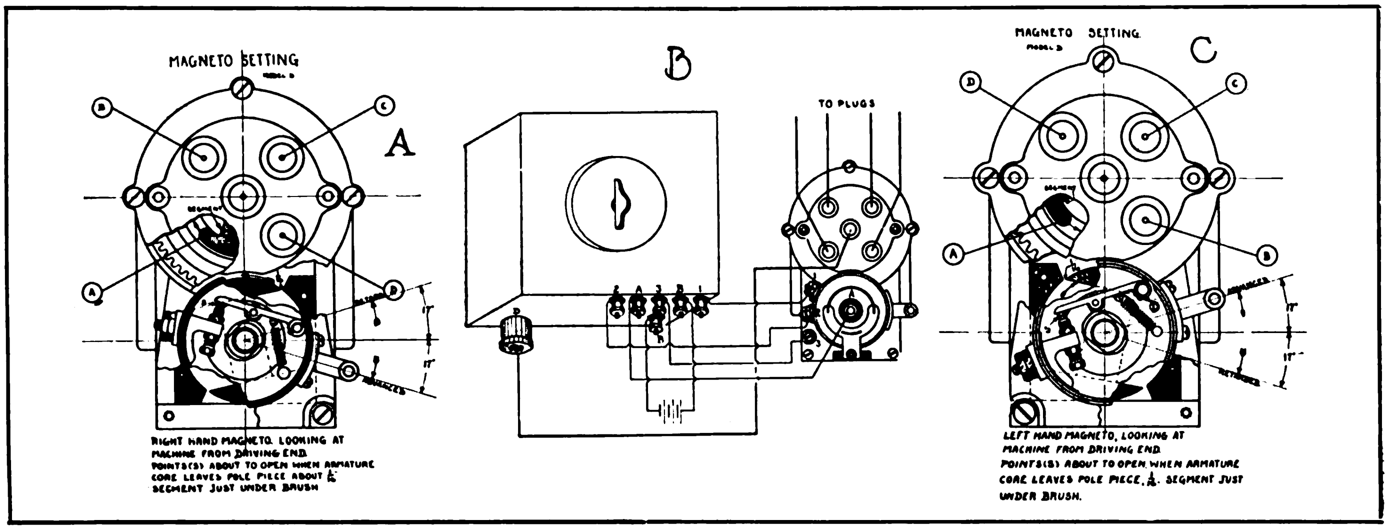
J. B. P.

New Rochelle, N. Y., March 15.

To change from one direction to the other, remove the breaker box, hold the driven end of the armature firmly with a pair of pliers and take off the small retaining or locking nut. Pull off the cam, which is keyed on with a Woodruff key, turn the cam over, replace the nut and reset it on the shaft with a prick punch so that it will not jar loose. Then remove the distributor block and the screws from the lettered ring. Remove the brass projecting cup on the distributor bearings, which will be found inside the inverted U formed by the magnets, and the top screw underneath the centre of the distributor shaft. The distributor and its gear can then be pulled forward out of mesh. Next set the distributor gear so that the position of certained and this must be observed as indicated in the drawing. It should also be borne in mind that the direction of rotation of the armature is opposite to that of the armature shaft, as the distributor is mounted upon a gear which is driven by another gear on the armature shaft.

The direction of rotation is necessary when connecting the high-tension cables from the distributor terminals to the spark plugs. The firing order of the motor must be known, and as all four-cylinder engines fire either 1, 3, 4, 2 or 1, 2, 4, 3, it is an easy matter to watch the intake valves and determine the order of explosions.

Assume that the distributor sector is in contact with the No. 1 cable indicated in the wiring plan at B, and the motor fires 1, 3, 4, 2: Here the distributor is rotating clockwise and as the next explosion occurs in the No. 3 the cup above the first member in the drawing is connected by cable with the third cylinder of



Illustrating the Setting and Timing of Splitdorf Magnetos: A, Diagram for Right Hand Direction; B, Wiring Plan of Vibrating Dash Type of Coil; C, Showing Proper Position of Armature When Driven Left Handed.

the segment will agree with A or C, as shown in the accompanying illustration.

After securing the magneto to its bracket or base on the motor, crank the engine until the piston of the first cylinder, that nearest the radiator, completes the compression stroke and is on dead centre. Next retard the spark advance lever on the steering wheel to its limit and connect the actuating rods, etc., to the spark advance lever on the breaker box of the magneto. If the armature shaft revolves in a clockwise direction looking at the driving end, the lever should be at its topmost position. If the shaft rotates anti-clockwise, the lever should be at the bottom limit and advanced upward.

Next revolve the armature shaft in its direction of rotation until the oval breaker cam comes in contact with the roller in the breaker bar and just begins to separate the platinum contact points. The points should begin to separate when the armature core leaves the pole pieces as shown in the sketch. It is important that the position of the bronze of the distributor be as-the motor. The next contact to be made in rotation is the cup to the left of the last named member, as the fourth cylinder fires next. The second cylinder is the last to be wired to the remaining terminal. It should be borne in mind in making connections that while the distributor sector makes a complete circle the cylinders do not fire in 1, 2, 3, 4 order, but 1, 3, 4, 2. By following the wiring diagram one should not have any difficulty in correctly installing the cables of this system.

The break of the platinum contact points should not be more than .03125 inch and these may be adjusted by loosening a locking nut and setting the screw member. If pitted the points should be trued up with a very fine file, taking care that a good, even contact is secured. In replacing the breaker box cover make sure that it is on properly and snugly, and that the brush member is in contact with the shaft. As will be noted by the wiring plan, both leads from the battery go to the coil and one is not grounded as with the battery and coil system of ignition.

RECENT MOTOR VEHICLE PATENTS

Hancock Throttle Control Device.

Milton T. Hancock, Jr., Los Angeles, Cal., has been granted a patent for a clutch pedal and throttle control for motor cars. It is a combination device in that the throttle opening may be controlled in much the same manner as when the conventional accelerator is fitted. A foot plate is movably mounted on the clutch pedal and is operatively connected to the throttle controlling means. Provision is also made for holding the foot plate in different positions relatively to the pedal and to retain the throttle at different adjustments. The construction is such that when the clutch pedal is disengaged the throttle may be closed automatically to prevent undue racing of the motor.

Holmes Coupling Links for Chains.

A coupling link for anti-skid chains has been patented by Edwin S. Holmes, Jr., Washington, D. C., assignor of one-half to Randolph T. Warwick of the same city. It is designed for connecting the cross chains to the side members and comprises a length of wire bent upon itself to provide a loop having parallel members and the terminal portions are bent to form oppositely disposed hooks with flaring bills. The shank or rear member of each hook projects backward at an angle to the contiguous member of the loop, one member of the latter having a hump at the inner side thereof on a plane with the bills of the hooks and the companion member of the loop having a similar hump toward the connecting portion of the loop. This forms a tortuous passage between the members of the loop.

Dobbins Tire Tool.

The tire repairing tool patented by Timothy C. Dobbins, Los Angeles, Cal., is designed to apply to tires, repairing devices comprising anchor plates adapted to co-operate with a clincher rim. The tool consists of an inserting lever having a gripping jaw adapted to engage on both sides and to support the anchor plate, while forcing the same into holding engagement with the rim. A co-operating holding lever is also included, so constructed as to engage the wheel and a pivoted link connection between the levers makes for alignment when utilizing the tool. A retaining device is secured to the levers to hold them in substantial contact throughout their length when folded together in an inoperative position.

Harper Piston Ring Remover.

In removing rings from the pistons considerable care must be exercised as the former are fragile and are broken easily. Horace G. Harper, Detroit, has been granted a patent for a piston ring remover which presents practical features and the device is simple in construction. It comprises a casing having a fixed stud which engages one end of the ring, and a movable member which engages the opposite end of the ring. These parts are inserted between the slot of the ring and by compressing a handle and ring member the piston ring is opened, permitting of slipping it over the piston. Means are included for holding the ends of the ring and to prevent slipping.

De Clairmont Spark Plug Tester.

A device for testing spark plugs has been patented by Adolfo De Clairmont, Toledo, O. It has spaced electrodes with bushings in connection and a transparent cylinder enclosing the bushings. Means are provided whereby either of the electrodes may be connected directly to a spark plug in a detachable manner, and a handle is secured to one of the electrodes.

Price Valve Lifter.

Charles Price, Clinton, Mass., has patented a valve lifter which differs from those of usual construction in that the valve spring may be held after compression by the tool, permitting of the use of both hands by the operator. It comprises a pair of levers pivoted at one end while the other extremities are provided with suitable jaws for engaging the spring and the valve tappet. The jaws of the lifter are compressed or extended by a loosely mounted screw and the upper part of the lever is provided with means for holding the adjusting screw after the valve spring has been compressed.

Dodwell Resilient Tire.

Malby George Crofton Dodwell, Wellington, New Zealand, has been granted a patent for a resilient tire having a plurality of windings, each extending throughout its length. The convolutions of each of the windings are arranged successively with respect to the adjacent members, and a second metallic member extends diagonally of the tire and intersects the convolutions of the windings of the first members. One of these is crimped at its intersections with the other member and has its convolutions lying within said crimp whereby the windings are bound together for the transmission of strains.

OTHER PATENTS GONE TO ISSUE.

Oil Can, Ralph A. Wakefield, Sacramento, Cal. The can is similar to those of conventional construction, but carries a spring actuated pin projecting from the bottom to the top of snout. By compressing the bottom of the oiler the pin is forced away from snout opening, allowing the lubricant to flow. Normally the spring retains the head member upon its seat, closing the aperture.

Fender, Charles G. Wegner, Baltimore, Md., assignor of one-third to Henry F. Sleepack and Amelia C. Wegner of the same city. It comprises a pair of parallel bars having bifurcated portions forming limbs connected to the axle and mudguards and a cross bar interconnecting the limbs, also a flexible covering.

Automobile Horn, Delroy Fifield, Cleveland, O. A horn actuated by the exhaust of the motor and comprising a tube having a partition therein and a valve disc. The latter has spring fingers embracing the partition, and is located at the mouth of the tube. A pipe is employed for conveying the gases toward the side of the disc opposite to the tube.

TRUCKS MINIMIZE FLOOD SUFFERING.

Food and Necessities Sent to Devastated Western Cities and Towns, and Quick Sanitation Measures, Save Thousands of Lives and Prevent Epidemics of Sickness.

THE world little realizes the extreme necessities resulting from the floods that devastated large areas of Ohio and Indiana, the rescue of people from places of peril, the transporting and distributing of supplies of food, clothing and fuel, and the removal of dead animals and refuse that might become sources of disease and even pestilence. With the railroads generally inoperative, save in sections, from destruction of roadbed and bridges, with telephone and telegraphic communication interrupted, with highways often washed away and seriously obstructed, the really prompt relief given was largely through the use of automobile vehicles. The haulage was by motor wagons and trucks, and driven by willing men these machines were worked almost continuously so long as there was pressing need.

The first attention was given to the collection and distribution of food, and when appeals were made to communities that were more fortunate, and whose people could give, motor trucks were loaded and sent over the roads with instruction to the drivers to go on if progress could be made. The national guard, the life saving crews and the officials of relief organizations followed, and with systematized endeavor the trucks and wagons were even more necessary and the work was extended wherever help was needed.

Dayton, O., the city that suffered the greatest from flood and fire, was the centre that demanded the largest measure of attention, and it was toward this community that the aid of the nation was extended. Food and clothing were the first essentials, then medical supplies, and with the subsiding of the water, sanitation was imperative because of the threatened danger from the accumulated refuse and the bodies of dead animals that were piled in hundreds in the streets and buildings.

The trucks and wagons from outside of the city were absolutely necessary in Dayton, for the larger part of those owned or used by inhabitants were wrecked or disabled by the flood, and some were submerged and could not be reached. Gov. Cox and J. H. Patterson, chairman of the Dayton relief committee, appealed to manufacturers of trucks to send vehicles there to be used in the relief and sanitary work. March 29 a series of telegrams were sent to different concerns and within two hours after receiving a wire General Manager Alvan Macauley of the Packard Motor Car Company had eight trucks on a special train. The following day at noon the machines were at work in the streets of Dayton, manned by expert drivers sent from the factory. The first one off the car carried a score of Red Cross nurses and their baggage to the National Cash Register relief station two miles distant, and the others followed with supplies of food, cots, clothing and medical stores. Following these machines came others sent by other manufacturers, and these were all delivered for service under the direction of the local relief committee.

March 31 the committee began the cleaning of the streets and the 25 Packard trucks of the National Cash Register Company, the eight factory trucks and other machines were used, while some carried supplies from the Fifth street station of the Pennsylvania railroad to the different relief stations about the city. In the sanitary work the trucks were used in pairs, skids and tackle serving to raise the bodies of the dead horses and cows from the streets to the platforms, one machine hauling the carcasses onto the other. The dead animals were taken to a temporary dump about two miles distant. With the trucks 50 carcasses could be moved daily, while with a team and wagon but 10 could be taken away. The trucks, carrying from four to six bodies, made the round trip in an hour. Occasionally the motor trucks were utilized to load the wagons.

Memorial Hall, Dayton, O., Which Was Used as a Relief Station During the Period the City Was Inundated and After the Flood Subsided.

Many of the machines were used for clearing the streets of debris and flood accumulations, others hauled the incoming supplies from the freight yards to the main relief station at the National Cash Register factory, some were used in distributing food and clothing to the different relief stations, and others were utilized

in all kinds of emergency work. In a week the trucks carried away more than 1000 dead animals, removed hundreds of tons of debris from the streets, and distributed the necessaries of life that sustained more than 100,000 people.

Had it not been for the motor trucks that were placed at the disposal of the local relief committee there would have been much greater suffering, and it is probable serious epidemic of sickness would have resulted from the retardation of sanitary work that could not have been accomplished without them. The generosity of the manufacturers in placing at the disposal of the relief committee both vehicles and men cannot be too highly praised, and the services possible by the use of the machines must be regarded as extremely valuable contributions.

What has been stated of Dayton is true, although in a lesser measure, with many of the smaller cities and towns where the relief of the sufferers was accomplished by the endurance of the tireless machines and

Removing the Dead Horses from the Streets of Dayton by Motor Truck, a Work of Great Necessity in the Prevention of Epidemic of Sickness.

unceasing efforts of the willing workers driving them.

Because of the destruction of thousands of horses by the floods, the animals in many instances being drowned in their stables, and the urgent necessity of transportation, there has been a very general demand made for motor vehicles of all kinds, especially those of the lighter types suited for fast delivery. Many manufacturers have been requested by their agents to give especial attention toward supplying this demand, and it is probable that motor vehicles will replace a good proportion of the animals. In one instance an agent made a call on a builder to have sent to him 50 light machines, there being so few animals remaining and the needs of the community so urgent. While this condition does not apply to all of the flooded areas, it may be said that the business men who have resources and require delivery or haulage service will seriously consider the utility of the motor vehicle, and it is probable there will be a very large increase in the use of machines as a result of the floods.

TO PRODUCE ENGINE PARTS.

New Concern Organized in Detroit Under Management of C. A. Goodspeed.

The Goodspeed-Detroit Manufacturing Company, Ltd., of Detroit, is a new company organized to build a factory to cost $20,000 on a $4000 site, in which will be made automobile engine parts. The concern has a paid in capital of $30,000, and the active head of the firm is C. A. Goodspeed, who is secretary, treasurer and general manager.

He was formerly connected with the Packard and Studebaker companies of Detroit, makers of high grade pleasure cars and trucks of the same names. The site of the new factory is on Harper avenue, opposite the plant of the Regal Motor Car Company, maker of Regal cars. The building will be two stories high and will afford a large floor area.

NEW ROTARY VALVE MOTOR.

Company to Be Organized to Produce Engine Designed by C. W. Sponsel.

C. W. Sponsel, formerly superintendent of the General Electric Company's plant at Pittsfield, Mass., is forming a company to be capitalized at $250,000, to manufacture the Sponsel rotary valve motor. Mr. Sponsel is working at present at Racine, Wis., but it is understood that Detroit capitalists are endeavoring to have the company locate in that city.

Mr. Sponsel has worked upon his invention for many years and his first patents were secured in 1903. It is stated that a balanced valve, eliminating about 150 parts found in a poppet valve motor, forms the principle of the new engine. A model is now being made in Detroit.

GARFORD TO HEAD CONCERN.

Well Known Truck Manufacturer Interested in Production of Aluminum Goods.

A. L. Garford of Elyria, O., formerly president of the Garford company of the same city, maker of Garford pleasure cars and trucks, is at the head of a new company recently incorporated with a capitalization of $100,000. With Mr. Garford in the venture are Walter F. Brown, chairman of the Ohio Progressive state committee, and Attorneys Sigmund Sanger and E. C. Froelich of Toledo.

The new concern is known as the Garford Engineering Company and it will probably locate its plant in Toledo. Its purpose is to develop a new process of producing aluminum with the strength of steel in all forms. Mr. Garford sold his control of the Garford company about two years ago to the Willys-Overland Company, but is understood to have retained a financial interest in the Elyria plant.

MORE THAN 50,000 SERVICE WAGONS BUILT.

INFORMATION received by the National Association of Automobile Manufacturers in response to requests sent to the 312 different listed concerns or individuals building service vehicles during February and March of this year, and collated as the second census of the motor vehicle industry, has been sent out in the form of a statistical report to the trade. It is decidedly interesting and, when compared with the figures of the first report made by the association a year ago, shows a remarkable development of the industry.

The facts contained in the report are of unusual interest. The comparison is made on the basis of reported production prior to 1911, and the number of vehicles produced during 1911 and 1912. This permits the use of three series of figures of assumedly known data, and to these are added the estimated output for 1913.

The requests for information sent to 280 gasoline and 32 electric vehicle manufacturers elicited 170 replies that were sufficiently definite to be included in the detailed report. About 40 per cent. of the firms or persons listed as manufacturers made no reply whatever, which apparently justifies the conclusion that they are not active or important. It may be that some are engaged in development or experimental work, while others may have produced vehicles in such small numbers that it was believed best to make no report, rather than have the reputation of building a few machines only.

The reports received from the 170 companies include 140 that make gasoline motor vehicles, 20 that build electric machines, one steam vehicle builder and seven makers of fire apparatus. Included in the electric classification are also the gasoline-electric machines.

In the statement relative to the production prior to 1911, 25 per cent. of the total reported has been added to provide for machines of which no record is available. To the figures for 1911 and 1912, 10 per cent. has been added to make up for any number not provided for in the reports. The estimate for the year 1913 is based on statements of anticipated production by manufacturers, and it may vary widely from the total given as the probable production.

The actual number of machines reported built prior to 1911 was 10,374, and during 1911 10,655 vehicles were produced, or a total for the industry of 21,029 up to 1912. During the year just past 21,929 wagons and trucks were turned out, this making a reported total to 1913 of 42,968. In the statement, however, 25 per cent. is added to the production prior to 1911, or 2594, which brings the total to 12,968 for that period; the same percentage added to the 1911 production adds 2664 and brings the total to 13,319, and with 10 per cent. added to the 1912 output, or 2194, the total is 24,133. The grand total of the industry until 1913 is given as 50,420 vehicles. The statement may be thus made:

Production Reported.			
To 1911	10,374		
1911	10,655		
1912	21,939		
		42,968	
Added for Discrepancies.			
To 1911, 25%	2,594		
1911, 25%	2,664		
1912, 10%	2,194		
		7,452	50,420

According to the reports received the estimated production for 1913 is 51,586, and to this is also added 10 per cent. to cover production not included in the reports, which makes the total estimated production 56,744. The valuation of the machines is given on the basis of the production reported, as follows:

To 1911	$20,485,231
1911	22,292,321
1912	42,942,828

It is estimated that the value of the production anticipated for 1913 will be $98,288,872.

The statement is made that aside from 12 to 15 companies, those that did not make report are comparatively new concerns that produced few or no machines during 1912, and the older or better established firms did not in any case build more than 50 vehicles.

It will be noted, however, that this statement applies to reported production, and it does not include a considerable number of converted pleasure vehicles, nor does it consider the number that have been built by individuals or concerns that could not be considered as manufacturers. So far as the added percentage for absence of reports, etc., it will be understood that this is apparently very large, but if this proportion will include the converted machines it will probably be very close to the actual figures of industrial vehicles in service today. The registration figures published by the MOTOR TRUCK last January, which ranged in date from Nov. 25 to Dec. 12, 1912, was the basis of an estimate of approximately 50,000 service wagons in use in the United States, and this was considered to be conservative and more accurate than anything previously published. This coincides closely with the report of National Association of Automobile Manufacturers.

The report sent out is interesting from the deductions made. According to the information supplied by 170 companies the machines built in 1912 were in number and in value as follows, in some instances the valuation being estimated:

Gasoline vehicles	20,052	$37,474,308
Gasoline vehicles	100	162,357*
Fire apparatus	140	843,900
Fire apparatus	135	813,760*
Gasoline tricars	58	23,610
Gasoline tractors	42	122,500
Electric vehicles	1,351	3,330,568
Mixed systems	59	163,800
Steam vehicles	2	8,025
Total	21,939	$42,942,828

*Production reported with no statement of value; estimate made on average price of other vehicles of the same character and capacity.

The estimated production for 1913 shows the following:

Gasoline vehicles	44,245	$83,073,200
Gasoline vehicles	1,775	2,620,847
Fire apparatus	232	1,422,250
Fire apparatus	260	1,595,200
Gasoline tricars	1,500	662,500
Gasoline tractors	800	2,125,000
Electric vehicles	2,736	6,627,750
Mixed systems	25	108,125
Steam vehicles	13	54,000
Total	51,586	$98,288,872

A comparison of the production of service vehicles is made that is based on the reports of 85 companies for the period previous to and during 1911, and for 117 companies for 1912, as well as for the estimate for 1913, with reference to number of gasoline and electric machines. This is:

	Reported by 85 companies		Reported by 117 companies	
	Sold prior to 1911	Sold in 1911	Made in 1912	Production for 1913
Gasoline	10,230	10,451	20,528	48,867
Electric	144	204	1,351	2,736
Total	10,374	10,655	21,879	51,603

Considering these for a moment it will be seen that the reports of the 85 companies are the basis for the figures of 1911 and the period previous to that time, with the addition of the 25 per cent.; that the figures of 117 companies practically are the basis of the estimates for 1913 as well as the production for 1912. There is a discrepancy in this statement of 60 vehicles as compared with the first tabulation of production, and of 17 in the number of vehicles shown in the third tabulation. While there is no doubt definite information lacking with reference to production in many instances, and the discrepancies are due to this fact, the statement relative to electric vehicles is insufficient, for it is certain that one concern alone in 1913 has built about 2700 machines, which is 1000 more than is credited as production to that time, to say nothing of the output of a number of other concerns that have produced vehicles for years in considerable numbers. The total number of electric service machines in use in the United States is uncertain, but more than a year ago a statement was made by the Electric Vehicle Association of America that 58 firms alone were using 2292 wagons and trucks, which is 600 more than the accredited production to 1913, and it is extremely probable that the aggregate of the vehicles in use is at least double the number given in the report.

The statement is made that the makers of gasoline vehicles have frequently changed models, this being demonstrated by the concerns making full report for 1912 and making estimate for 1913, where 35 types have been discontinued and 44 new models added, while during the same period 12 electric models were discontinued and five begun. With the gasoline vehicles these changes are most noticeable with machines of 2500, 3000, 5000, 6000, 7000 and 12,000 pounds, and with those of 1500, 2000, 3000 and 7000 pounds capacity in the electrics. In manufacturing the capacities of vehicles produced in largest numbers are the 1000, 1500, 3000, 4000, 6000 and 10,000 for gasoline machines, and the 1000, 2000, 4000 and 7000 sizes in the electrics.

According to the report the average price of all vehicles built in 1912 was $1957.37, that of the gasoline machines being $1868.95 and of the electrics $2465.18. The average price for 1911 for the gasoline vehicles was $2079.16 and $2759.66 for electric wagons, and the average price for the period prior to 1911 was respectively $1955.70 and $3369.72. In comparison of prices it is found that the average prices of the 1500, 3000, 4000, 8000 and 10,000-pound gasoline machines have decreased materially during the period of years, and the prices of the 2000 and 6000 sizes have increased, while with the electric vehicles the average prices of the 1000, 2000, 4000, 8000 and 10,000 sizes have been reduced, and the prices of the 1500, 3000, 7000 and 11,000-pound sizes have increased. For 1913, basing the estimate on the prices reported, the average cost of the gasoline vehicles will be $1877.57, and of the electrics $2422.44.

EXPERIMENTAL STREET PAVING.

Tests to Determine the Surfacing Most Enduring Under Traffic Proposed for New York.

Because of the agitation by some New York legislators who are interested in the enactment of a proposed bill in the general assembly of that state, and who base the claim that service wagons should be taxed at $5 a ton capacity on the contention that they are destructive of the streets and highways, men identified with the motor vehicle trade are devoting their energies toward controverting these arguments and the general public impression that might be made.

Morris R. Machol, general manager of the Hydraulic Truck Sales Company, New York City, believes that to determine the class of road that will best meet the traffic conditions, and to ascertain what particular class of traffic does the most damage to the roads, it would be well to lay experimental paving where the traffic would supply the differing conditions and closely observe the results. He maintains that the wear of a road surface is entirely dependent upon the weight a square inch upon it, and that it is in every way practical to regulate this weight by the proportions of the tires. That is, the width of the tire should be proportionate to the load upon it, and with reference to the diameter of the wheel and the speed of the vehicle. He suggests that the experiments with paving could be made by automobile engineers and road builders jointly with a view of learning what changes might be desirable, if any, in vehicles and road construction methods.

The General Motors Truck Company announces that Assistant Sales Manager E. J. Kilborn has been made general manager of the Chicago district of the company's organization, and that Otto Stoll, manager of the St. Louis branch of the company, has been appointed assistant sales manager.

BRIEF NEWS OF MANUFACTURER AND THE TRADE

The development of the plant of the General Vehicle Company at Long Island City, L. I., which has been progressing since last autumn, and which will be completed during the present year, will involve an expenditure of nearly $1,000,000 in new buildings and equipment. The demands upon the manufacturing department which were considerably in excess of the facilities a year ago, and the acquisition of the American rights to manufacture the Mercedes gasoline trucks, compelled a very large increase of the manufacturing plant. The original building is a two-story brick structure 100 by 520 feet, having a floor area of about 105,000 square feet, in which until the completion of the new buildings the general offices and the production departments will be located. Contiguous to this a structure 75 by 500 feet, six stories, is now being erected, and this is to be one of the finest in the world. It has a steel frame and is of concrete faced with red brick. It has as a foundation 1206 concrete piles of an average length of 32 feet. The purpose is to devote the five lower stories to the production of electric vehicles, and the sixth floor to the general offices. In this will be four elevators, two for passengers and two for vehicles. The building will cost, without tools, at least $500,000. When this structure is ready for occupancy the electrical division will be moved to it, and the present building will be remodelled and will be a machine shop and assembly room for the Mercedes truck division. The third building, which is yet to be built, will be of brick and concrete, one story, 50 by 240 feet, and this will also be given over to gasoline truck production. The machine equipment of the buildings will be in every way complete and every labor saving and economical tool will be utilized. When the plans were originally made it was expected to rapidly complete the buildings, but numerous delays have been experienced, including engineering problems and uncertainty of street changes, which would affect the large real estate holdings of the company.

The Kissel Motor Car Company, Hartford, Wis., maker of KisselKar trucks and pleasure cars, has appointed the following distributors: Brooks Auto Company, Turlock, Cal.; F. H. Davis, Placerville, Cal.; Geyer & Boroski, Colusa, Cal.; J. S. Gill, Pleasanton, Cal.; W. W. Head, Chico, Cal.; W. J. Booth, Lebanon, Ore.; C. R. Canfield, Willamina, Ore.; John Gray, Roseberg, Ore.; E. E. Leas, Oakland, Ore.; W. J. Benbenick, Bremerton, Wash.; G. A. Thomas, White Salmon, Wash.; B. N. House, Cle Eluni, Wash.; McGhee Auto Company, Kent, Wash.; Hugo A. Gutenkunst, Owen Sound, Ont.; Morrin-Thompson Company, Phoenix, B. C.; J. F. Austin, Monterey, Mexico; C. R. Miller, Stockholm, Sweden; Saskatchewan Garage, Moose Jaw, Saskatchewan; B. E. Munson, Crow's Landing, Cal; E. T. Neal, Paso Robles, Cal.; F. O. Taylor, Ukiah, Cal.; Wisnom-Bonner Hardware Company; San Mateo, Cal.; F. M. Wyatt, Winters, Cal.; Western Auto Supply Company, Reno, Nev.; Elko Auto Company, Elko, Nev.; McCoy & Veazie, St. Helena, Ore.; S. A. Mills, New Berg, Ore.; Newmith Auto Company, Salem, Ore.; A. Wilhelm & Sons, Monroe, Ore.; J. J. Wirtz, Forest Grove, Ore.; Ernest Peterson, Mt. Vernon, Wash.; M. M. Stewart, Aberdeen, Wash.; Twin City Auto Company, Chehalis, Wash.; Yakima Auto & Supply Company, North Yakima, Wash.; Knueppel & Ott, Davenport, Ia.; Barre KisselKar Company, Barre, Vt.; Johnson & Stevens, Booneville, Mo.; Hodge's Garage, Greenpoint, N. Y.; Edward J. Deasy, Glen Cove, N. Y.; Hackensack Auto Service, Hackensack, N. J.; O. R. Hukle & Co., Lexington, Ky.; Chandler & Hightower, Ft. Worth, Tex.; Boulevard Garage, Bridgeport, Conn.; Taximeter Auto Company, Paterson, N. J.; W. A. Platt, Mountain View, Cal.

The Summit Auto Company, Akron, O., has been incorporated, with a capital of $10,000 to deal in trucks and pleasure cars, by E. J. Eblen, J. M. Lauder, F. L. Matz, Rachel Lauder and Almira Eblen.

The Available Truck Company, Chicago, has moved to a larger factory in which its capacity will be doubled. New machinery has been installed. The officers of the concern are: President and general manager, John Rath; secretary and sales manager, E. F. King; treasurer, R. C. Blume.

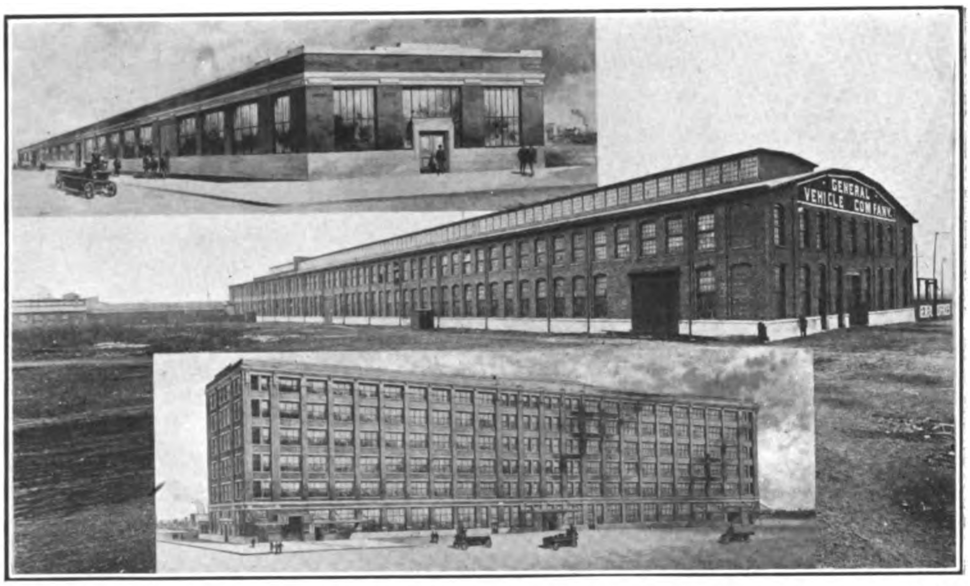
The Manufacturers' Association, Chattanooga, Tenn., is negotiating for the establishment of a motor truck factory in that city. The company will be capitalized at $100,000.

The Four-Wheel Drive Auto Company, Clintonville, Wis., maker of Four-Wheel Drive trucks, has increased its capital from $50,000 to $250,000. The additional stock has been sold and extensive additions will be built to the factory. The plans call for three buildings and 500 men will be employed when they are ready for occupancy.

The F. L. Moore Motor Truck Company and the Pacific Metal Products Company, San Francisco, Cal., have consolidated under the name of the latter concern. The capital stock is $1,250,000 and plans are being made for a large truck factory at Torrance, Cal.

The Kardell Motor Car Company recently took over the business of the Chase Motor Truck Company of St. Louis, Mo., and will handle the Chase line, made by the Chase Motor Truck Company, Syracuse, N. Y.

George H. Albertson, formerly president of the Duquesne Sanitary Company, Pittsburg, Penn., and his son, Wilbert Albertson, have opened an establishment at 429 Liberty avenue, that city, known as the Vulcan Service Motor Truck Company. The concern handles the Vulcan service truck, made by the Driggs-Seabury Ordnance Corporation, Sharon, Penn., and the Service motor truck, made by the Service Motor Truck Company, Wabash, Ind.



General Vehicle Company's Plant at Long Island City, L. I., and the Buildings Now Being Erected: In the Centre, the Present Building; Above It the New Structure for the Gasoline Truck Department and Below It the Building to Be Occupied by the Electrical Division.

H. P. Barnstetter has been appointed assistant sales manager of the Chicago branch of the Kissel Motor Car Company, Hartford, Wis., maker of KisselKar trucks and pleasure cars.

L. H. Wessels has been appointed Philadelphia branch manager of the Chase Motor Truck Company, maker of Chase trucks, at Syracuse, N. Y.

The Standard Roller Bearing Company has opened a branch office in the State Life building, Indianapolis, Ind., in charge of L. M. Watkin, Jr.

C. Robert Hoyme, prominent in the automobile business of Philadelphia for the past seven years, has been appointed manager of sales and service of Alco trucks, made by the American Locomotive Company, New York City. Mr. Hoyme previously was sales manager of the International Motor Company

branches at Philadelphia, Baltimore and Washington, and before that he was associated with the Autocar Company.

The Standard Welding Company, Cleveland, O., maker of Stanweld rims, seamless steel tube and other products, announces the resignation of R. M. Hawkins, formerly assistant purchasing agent.

Harry C. Tillotson, formerly a director and treasurer of the McDuffy Automobile Company, is now a director and secretary of the Stromberg Motor Devices Company, maker of Stromberg carburetors and motor accessories. In addition to the active duties of secretary he will have personal supervision of the sales.

Dwight Holmes of 1231 South Flower street, Los Angeles, Cal., has taken the distributing rights for his territory for Speedwell pleasure cars and trucks, made by the Speedwell Motor Car Company, Dayton, O. His son, G. S. Holmes, will operate the agency for the same line at 121 South State street, Salt Lake City, Utah.

C. E. Martling of New York City recently succeeded H. P. Childs as local branch manager of the International Motor Company, in that city, the latter being promoted to become assistant eastern sales agent.

E. A. Stone has been appointed manager of the new factory sales branch in Indianapolis, Ind., of the Republic Rubber Company, Youngstown, O.

The Studebaker Corporation, Detroit, maker of Studebaker trucks and pleasure cars, preparatory to the spring and summer business, located its branches in new homes in the following cities: St. Louis, Mo.; Atlanta, Ga.; Omaha, Neb.; Minneapolis, Minn.; Salt Lake City, Utah, and Washington, D. C.

W. T. Norton of the Selden Motor Vehicle Company, Rochester, N. Y., maker of Selden trucks, has been promoted to the position of general factory superintendent and will have complete charge of the production of both passenger cars and trucks.

William D. Paine, formerly with the United States Motor Company, Philadelphia, Penn., and recently with the Studebaker Company of that city, has joined the forces of the E. V. Stratton Company, Albany, N. Y., as representative in the Troy district of Stewart and Hudson commercial vehicles.

W. H. Wood has been appointed manager of the commercial vehicle department of the Waverley Company, Indianapolis, Ind., succeeding A. L. Dixon, resigned. Mr. Wood was formerly connected with the Westinghouse Company, Pittsburg, Penn.

The Brooks-Norton Motor Sales Company, Cleveland, O., has moved into new quarters at 2169 East Ninth street. The company handles Schacht and Modern trucks.

The E. V. Stratton Company, Albany, N. Y., distributor for Stewart trucks for eastern New York and western Massachusetts and Vermont, has leased for a term of years the premises now occupied by C. S. Ransom on Chapel street, opposite the Hotel Ten Eyck. The building will be refinished inside and out, with stock and supply department and offices fitted up at the rear, and an attractive show room at the front.

F. N. Schwab has taken the position as manager of the Chicago branch of the Speedwell Motor Car Company, Dayton, O., maker of Speedwell cars and trucks.

Arthur G. Kerrigan, for many years with the Autocar Company's branch at Boston, has resigned to join the sales force of the R. & L. Company, eastern distributor of Garford trucks and pleasure cars, at 915-921 Boylston street.

VOL. IV. PAWTUCKET, R. I., MAY, 1913 No. 5

HARDEST WORKED TRUCKS IN AMERICA.

Fleet of 67 Garford Machines in Service of the New York Mail Company, Used Practically Night and Day and Often Exceeding 100 Miles Daily, Yields Surprising Economy.

By William W. Scott.

WHAT can be regarded as the hardest worked fleet of motor vehicles in America, and there are some installations that have exceedingly hard service, is that used by the New York Mail Company, which has the contract for the haulage of mail in New York City, south of Forty-second street. The only other that parallels it is the installation of the Motor Service Company, which has a similar contract north of Forty-second street. The vehicles of the New York Mail Company are of one make, the Garford two and three-ton gasoline wagons and trucks, and in this it is also paralleled by the Motor Service Company, which has a complete electric equipment—all General Vehicle machines.

But the work that the New York Mail Company is contractor for is decidedly larger than the other, and it keeps the 67 machines at work practically every minute. It is extremely important, for the New York postoffice handles daily a far greater volume of mail than any other similar branch of the government service. There are many reasons for the enormous importance of the New York mail to the nation and the world. New York is the commercial centre of America, and it is second only to London in international commerce. The mail is the logical and generally accepted method for transacting business. Eliminate the mail and commerce and industry the world over would be paralyzed. As an illustration of the value placed upon time in the delivery of mail, one of the most forceful arguments made to attract tenants to the new Woolworth building in New York is its proximity to the general postoffice, where the mail is delivered earlier than delivery can be made in structures further away, an economy estimated to be 15 to 20 minutes in time with reference to any given round by the carriers.

Three-Ton Garford Truck and Standard Straight Side Postal Service Body Used by the New York Mail Company.

The New York Mail Company's present contract will expire at midnight, May 31, and it is probable that before that time another contract will be made by the postoffice department. The existing contract was for a period of four years and it was entered into June 1, 1909, the bids having been made on a basis of horse service. This contract provides for the transfer of the mail between the general postoffice and the branch postoffices of the borough of Manhattan south of Forty-second street, and between the postoffice and the branch postoffices and the railroad terminals, and the haulage of the incoming European mail to the postoffice, its branches and the railroad terminals.

The New York Mail Company succeeded itself as

contractor for the work. The haulage of the mail in a city of large proportions is a work that cannot be taken over by a contractor, as might be practical or possible with other work. Mail transportation is a business that requires the greatest care and intimate knowledge of conditions, and it has been customary with a contractor taking a new contract to take over the equipment and employees of the predecessor, because it would not be possible to conform to the requirements of the contract without a well trained and efficient organization. For this reason, while contractors may change, the mail service goes on without interruption.

The New York postoffice is the most important of the postal system of the United States. From this is distributed many hundreds of tons each day, and a volume that is correspondingly large is received. New York is the largest publishing centre of America. The publications, newspapers, periodicals, books, etc., to say nothing of the advertising and trade promotion literature, are distributed through the mail. The letters sent out daily number millions. It must not be understood that the contractor that is the subject of this article had to do with all of the postal service of New York, because the Motor Service Company has the contract for the northern section of Manhattan and the Bronx, and other contractors have the work in the other boroughs that include Brooklyn and Staten Island. In addition to this all the outgoing European mails are transported from the general postoffice to the different steamship lines by the steamship companies, and the collection of the mail from the mail boxes and the sub-stations is done by other contractors.

Two-Ton Friction Driven Garford Wagon, Equipped with Standard Covered Express Body with Flared Sides.

It is difficult to estimate the number of men and vehicles actually engaged in handling the mail received and dispatched from New York, but there are several thousand employees and several hundred vehicles. Besides all this there are numerous mailing companies, which prepare mail for delivery to the postoffice, and in some instances these deliveries are made to the postoffices or are sent to the railroad terminals under the supervision of clerks of the postal service. Besides this, some of the large concerns doing mail order business deliver their own mail to the railroad stations practically made up and pouched, and one of these sends a three-ton truck of mail to the Pennsylvania railroad terminal each half hour of the day from 8:30 in the morning until 6:30 or later at night.

Since the inauguration of the parcel post, Jan. 1, the work of the postoffice has been greatly increased. The New York Mail Company in its contract area handles more than 30,000 packages each day, and this number has been growing so rapidly that it is difficult to keep pace with the requirements. The small packages are pouched, but the larger parcels are handled without pouching. The bulk of the packages is one of the conditions that cannot be anticipated and of course in handling these varying requirements must be met as they become known.

With relation to the incoming European mail: This is all made up on the steamers and no less than six reports are received, the first from Cape Race and ending with one at Quarantine, where the mail is transferred to the postal lighters. In transferring the pouches there is a lighter at either side of the ship and as the mail sacks are brought up in large nets it is divided on the deck and that for the city goes to one lighter and that for other destinations to the other. The number of sacks is reported to the contractor and wagons are dispatched to Pier 13 for the city mail and to Pier 83 for the other. The city pouches are taken to the general postoffice, and the outside mail is taken to whatever railroad terminal it is dispatched over.

It is not possible to anticipate the arrival of European mail with sufficient accuracy to have it regularly scheduled, and the volume varies materially, but it is not unusual to have as many as five steamers arrive in a single day, and sometimes there will be intervals of several days between arrivals. It will be seen that the requirements fluctuate decidedly, for occasionally there are several thousand pouches in a single arrival. When mail is received it is necessary to transport it without delay, and this must be done in addition to the work of the domestic postal department.

The contract for mail transportation is always begun at midnight and continues for a definite period. The service is specified by the department, and this is usually on the basis of a certain volume to be hauled between stated points. This is to be hauled at stated trips, the time of departure from an initial point and the time of arrival and departure at the intermediate points, and the time of arrival at the objective point all being fixed. This may be applied to any number of

trips between the general postoffice and the branches and the railroad terminals, and when the work has been thus specified it is necessary for the contractor to determine how he can meet the requirements with the fewest number of vehicles. A specified price is paid for the stated service, and if it is possible to so arrange the haulage that a lesser number will do the work the postal department is satisfied. As a business proposition it is necessary for the contractor to so systematize his service that he can do it with the least possible number of men and vehicles.

It is necessary in making out the schedule for each work to have each vehicle leave and arrive on time, and in no instance is a wagon permitted to arrive or depart ahead of the time fixed, save at the final or objective point, which may be reached ahead of the time set. What is regarded as a reasonable time is allowed between points, and no matter what the circumstances, unless it is entirely beyond the control of the contractor, there is no excuse. This schedule must be maintained under all conditions, winter or summer, the only provision made for extremes of snow or sleet or fog being that when the snow is very deep a "headway" is established, which means stated intervals between trips for the period the adverse conditions obtains, and when the fog obstructs the North river and prevents the trips of the ferries with regularity the wagons are dispatched with a larger margin of time to make deliveries at the railroad terminals in Jersey City, for the contract calls for haulage to the railroads in that city.

The New York Mail Company had 520 horses in its service when the present contract was made and sufficient wagons, single and for two-horse teams, to meet the requirements. After 18 months the first motor wagons were installed. The first installation numbered 16, and the big stable at 531 East Fifteenth street was used in part as a garage. This is a five-story structure and in it at that time was a blacksmith shop, wheelwright shop, harness shop, paint shop, and the company did all its necessary work for the maintenance of the wagons and harness and the shoeing of the horses. Besides this it had another stable in East Twentieth street, where a considerable number of horses were kept.

After the first use of motor wagons the horses were gradually disposed of until about a year ago the entire service was motorized, there being now in use 67 Garford wagons and trucks, 27 of two tons capacity, these being of the friction drive type, and 40 of three tons capacity, these being of the conventional chain drive with a three-speed ratio and reverse gearset in the power transmission. These are all equipped with covered express bodies, with screen sides and rear doors, which are loaded from the rear. The two-ton wagons have an extension hood built with the body, but the others have cabs for the driver, behind which the bodies are installed. The wagons are all built with the motors under floorboards.

The company has 240 employees in its organization, there being two drivers for each vehicle and a sufficient number of drivers to provide for emergencies, accidents and the like. Each man has what is known as a "tour," which calls for 12 hours' work, and each machine is expected to cover an average of 48 miles to a tour, so that under normal conditions each machine in service will make 96 miles daily. But as a matter of fact some of them make much more than that mileage. Extra trips must be provided for and these are the result of an excess of mail. The additional vehicles are provided at notice being given, the company having an hour in which to supply what number may be required to relieve any particular route. For this extra service the company is paid a stated price a trip. The wagons are all dispatched by a dispatcher at 531 East Fifteenth street, but there are additional dispatchers at the general postoffice, and the Grand Central and the Pennsylvania railroad terminals.

No Delays Are Permitted and the Garage Repairers Work on the Trucks in the Street Unless the Job Is of Considerable Proportions.

The wagons are generally brought to the garage for an exchange of drivers, to have repairs, etc., but the company also has garages at 9 Ninth avenue and 530 East Twentieth street, and it is not infrequent that a machine will be sent out and placed on a route where it will not return to the East Fifteenth street garage for a week or more, being kept at work day and night so long as it is operative. This means that in some instances a truck will be worked 96 or more miles each day for seven or more consecutive days, and the aggregate mileage for a month is exceedingly high.

The machines are inspected as often as they reach the main garage and of course they are sent there

whenever attention of any kind is needed, but the intention is to have all the work that can be done performed during the day. The garage equipment includes a shop with all the necessary machine and hand tools and a complete stock of parts of all kinds, and a force of men experienced with the machines. The time of each vehicle is a large asset with the company and this has been accentuated by the expiration of the contract June 1, and the company has endeavored to do the work with the machines it has, not desiring to spend money for additional equipment until after the award of the new contract.

So far as possible the machines are not withdrawn from service. When it is possible to do so the work on them is done in the street, and because of the demands the vehicles are not even painted. The wagons and trucks are washed and the mechanism is given careful attention, but aside from this nothing will be done until the expiration of the contract, simply because of the inability to spare one for any length of time. As an illustration of the work that is done by the machines it may be stated that the postal department Jan. 1 last advertised for bids for the work, specifying that the contractor should have 40 3000-pound and 20 1500-pound wagons, but with the additional demands for transportation through the parcel post and the probable increase during the period covered by the contract, the specifications were withdrawn and bids were invited which specified the services of 80 three-ton trucks and 20 1500-pound wagons. The increase of capacity can be realized when it is known that the aggregate capacity for which bids were first asked was 75 tons, and the bids are now open for vehicles having a capacity of 270 tons. As each machine will be expected to haul many tons a day this will give some idea of the magnitude of the contract.

With the machines now in use it would not be possible to do the work were it not for the fact that they have the right of way through traffic and cannot be unnecessarily delayed, and that a large part of the work is done during the night, when the streets are comparatively free. The haulage is very heavy during the nights until 3 in the morning, for there are the mails for all the night trains to be transported, as well as the flood of newspapers. The newspapers alone make a good part of the mail, there being trains made up that run to Chicago and St. Louis that carry nothing else, as well as the heavy newspaper mail to practically every point in the country. Between 3 and 6 in the morning is probably the lightest part of the day. A good deal of mail is sent to the Grand Central station from the general postoffice by pneumatic tube, but when the tube service fails the company is required to transport the pouches that would be sent by other means.

The company has an emergency crew and wagons at the East Fifteenth street garage that is constantly on call. Should a loaded wagon, and they are loaded practically all of the time, be disabled, the emergency crew starts carrying whatever may be necessary to meet the requirements. If it is possible to do so the disabled machine is towed to its destination, for it requires time to make a transfer of the mail, and it cannot be done except under the supervision of a clerk, who must be sent for. If a wheel is broken, or the damage is such that a transfer must be made, this is done and the repair is made in the street that will permit the wagon to be taken to the garage, but if it can be towed the load is delivered and another wagon is given to the driver to continue his work. Then the disabled vehicle is towed to the garage. So expert have the emergency men become that they can handle a towed wagon through traffic and often keep to the schedule requirements. Sometimes, if the machine can be operated, but has not power, the emergency wagon will be driven behind it, pushing it up grades and along through snow.

Type of Enclosed Body on Garford Truck That Has Been Discarded by the Postal Service for the Standard Express Type.

With the conditions as they are, with the machines worked to the limit, it is not practical to make comparisons with what might be accomplished with animals, but it is the belief of Supt. George N. Magee that it would require more than 600 animals to do the work that is now being done with the 67 machines. The horses, wagons, harness, and other equipment would mean a very large investment, and horses do not last long in this kind of service. The animals cannot be favored and it is policy to keep the equipment at the lowest point possible. With the animals a considerable expense would be ferry charges, which run as high as 60 cents with some ferries, and with the numerous

hauls to Jersey City the aggregate is a considerable sum daily.

The company has plans made that will, if it receives the new contract, mean the purchase of additional equipment and the establishment of a large garage, but this cannot be determined until the result of the bids is announced. As the vehicles are worked it is not possible to make comparative statements that would be applicable to other service, but it is certain enough that there is not another fleet of wagons that does anything like the volume of haulage that is done by these 67 machines.

S. A. E. SEMI-ANNUAL MEETING.

Will Entertain British Institution of Automobile Engineers for 18 Days.

The members of the British Institution of Automobile Engineers who will be the guests of the Society of Automobile Engineers, and who will participate in the semi-annual meeting to be held at Detroit, will arrive in New York on the steamship Minnewaska May 26. The visitors, several of whom will be accompanied by members of their families, will number 40 or more. They will be received by the officers of the society, the general committee of arrangements and the New York local committee. The first day will be devoted to a baseball game and a dinner and the second day to sightseeing and the May session of the metropolitan section of the S. A. E.

May 28 the visitors and the S. A. E. members will go to Pittsburg, remaining there a day and leaving the evening of May 29. The morning of May 30 the company will reach Indianapolis, and will witness the races at the speedway, leaving there the evening of May 31 and reaching the city of Detroit the morning of June 1.

Monday, Tuesday and Wednesday until 3 in the afternoon, will be devoted to visiting several of the manufacturing plants, theatre party and a banquet, and then the members of the S. A. E. and their guests will embark on the steamer Detroit III, reaching Sault Ste. Marie the evening of June 5 and leaving several hours later for Mackinac island, where a stop will be made the afternoon of June 6.

The return will be made to Detroit, which will be reached at 3 the afternoon of June 7, and that evening the visitors will depart for Cleveland, where they will arrive the morning of June 8. The day will be devoted to sightseeing and the following day to visits to different plants and to tire factories at Akron. The departure will be made the evening of June 9 for Buffalo, where the day will be given over to a visit to the Pierce-Arrow Motor Car Company's plant and to Niagara Falls.

Here the party will divide, some going to New York and the others to Providence, where June 11 a day will be passed at the works of the Brown & Sharpe Manufacturing Company. That night the visitors will go to Bridgeport, where the morning of June 12 will be devoted to inspection of several manufactories, and that afternoon the journey will be made to New Haven by automobile. The night will be passed there and the following day the engineers and their guests will be driven to Hartford, where several automobile, tool and tire factories will be inspected. The return to New York will be made by boat, which will be reached the morning of June 14.

The programme of the morning session, June 5, following the transaction of business, will include reports by Henry Souther, chairman of the iron and steel division, and by David Fegusson, chairman of the ball and roller bearings division; papers by Enrique Touceda on the "Manufacture and Physical Properties of Malleable Iron," by K. W. Zimmerschied on "A New Tensile Test-Piece and Holder," by Paul W. Litchfield on "Pneumatic Tires," and by Harry Tipper on "Lubricating Oil," while the topics for discussion will be the "Design and Treatment of Leaf Springs" and "Worm Gears."

The afternoon session the same day will be devoted to the commercial vehicle section, and will include papers by T. B. Browne, president of the Institution of Automobile Engineers, on "Public Service Vehicles"; by Thomas Clarkson of the Society of Motor Traders & Manufacturers, on "Steam Buses"; by Charles Wheeler of the Institution of Automobile Engineers, on "Calculating Depreciation of Commercial Automobiles"; by Arthur M. Laycock on "Jackshaft versus Double-Rear-Wheel Brakes"; by Arthur J. Slade on "Metal Wheels"; reports by William P. Kennedy as chairman of the truck standard and commercial car wheel divisions, and "Comparative Efficiency of Solid Motor Tires" will be discussed.

The morning session of June 6 will be given to papers by F. F. Beall on "Automobile Production Inspection Methods," by F. E. Moskovics on "The Influence of the Sales Department on the Design of Motor Cars," by George W. Houk on "Wire Wheels," by Claude E. Cox on "Motor Construction"; reports by Chairman Andrew L. Riker of the electrical equipment division, by Chairman C. W. Spicer of the broaches division, by Chairman Henry Souther of the pleasure car wheels division, by Chairman Elliott J. Stoddard of the nomenclature division, by Chairman Arthur Holmes of the miscellaneous division; and to the discussion of "Electric Motor Starters," "Possibilities and Limitations of Utilization of Electricity in Operative Motor Car Function," "Possibility of Weight Reduction in Motor Car Design" and "Hobbing Methods."

The concluding session the morning of June 7 will include papers by E. B. Wood of the Institution of Automobile Engineers on "Engine Testing"; by Herbert Chase on "Motor or Carburetor Test Data"; by Prof. L. V. Ludy on "Tests of Automobiles"; a report by Chairman John O. Heinze of the motor testing division, and there will be discussion of the subjects of "Gasoline Motor Fuels," "Carburetor Nozzle Action" and "Motor Manifolds."

THE G. C. KEROSENE VAPORIZER.

NEARLY a year ago MOTOR TRUCK presented to its readers a description of the G. C. heavy fuel vaporizer, the invention of a Roumanian engineer, which was fitted to a large number of trucks in the service of an English company. Since the publication of the article the vaporizer has been improved and it is now being manufactured by the G. C. Vaporizer Company of America, Inc., 1790 Broadway, New York City.

The difficulty attendant upon the use of heavy fuels, that of vaporization, is held to be overcome by the G. C., which utilizes the exhaust gases of the motor in a novel manner. The engine is started on gasoline with the conventional type of carburetor and after being run a few minutes to obtain the desired heat, is then operated on kerosene, the vaporization of which is accomplished independently of the carburetor. A feature of the G. C. is that it may be employed with any type of internal combustion motor without alteration or interfering with the use of the usual carburetor and fuel. This is an advantage as it would permit of utilizing gasoline or kerosene as desired.

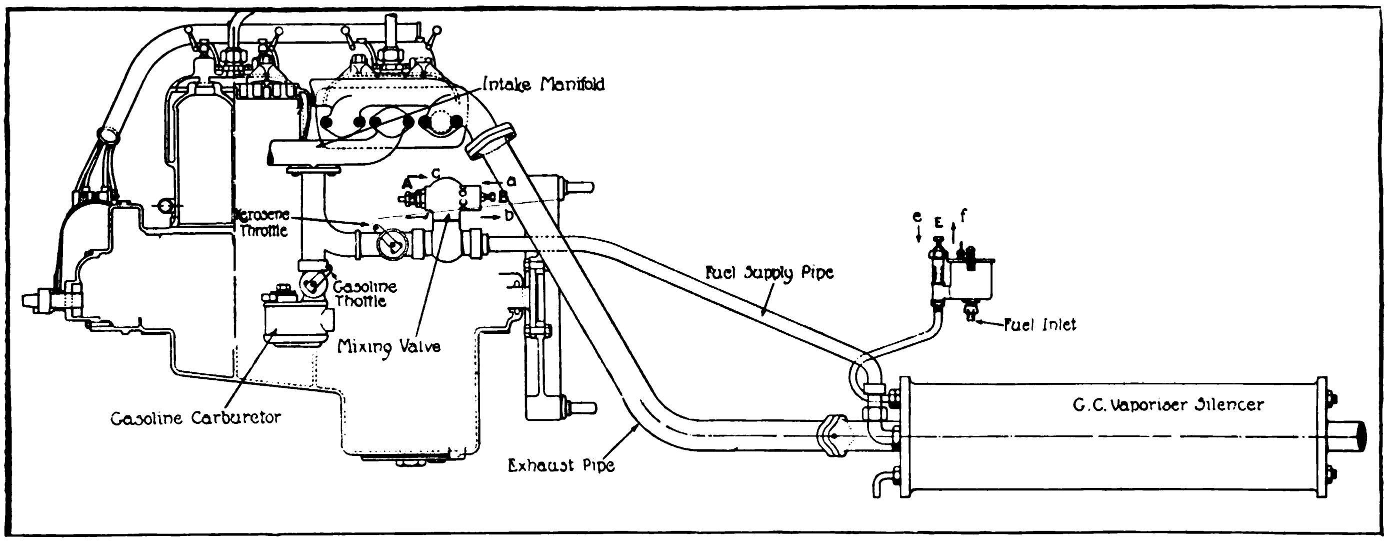

Fig. 1—G. C. Vaporizer, Replacing Usual Muffler and Vaporizing Heavy Fuels by Utilizing Heat of Exhaust Gases in a Novel Manner—Its Use Does Not Interfere with Operation of Motor on Gasoline, Making for a Dual Fuel System.

As will be noted by the accompanying illustrations the vaporization of the heavy fuel is obtained by a specially designed muffler, or vaporizer as it is termed, and the vapor is led to a mixing valve piped to the intake manifold of the engine. A longitudinal section of the vaporizer is shown at Fig. 2, also an end view and a section. The general arrangement is presented at Fig. 1. It will be seen that it differs from the gasoline carburetor in that no attempt is made to atomize the fuel as it issues from a jet. Instead, the heat of the exhaust gases is employed to slowly distill and vaporize the kerosene or heavy fuels.

The exhaust gases of the motor enter the vaporizer and go through three complete passages before passing out at the exhaust inlet. The kerosene is drawn into the vaporizer by a partial vacuum produced by the suction of the motor and passes through a horizontal pipe having a larger number of holes .145 inch in diameter. The fluid percolates through these fine openings at the rate of about 25 drops at a time, and coming in contact with the particles of cast iron utilized to retain the heat, is instantly vaporized. The metal mass is so arranged as to permit of the passage of the kerosene vapor, mixed with ordinary air, at very low speed and at a very high temperature of from 550 to 750 degrees Fahrenheit. The mixture ultimately obtained is at the comparatively low temperature of about 122 degrees Fahrenheit owing to the introduction of the outside air in the air mixing valve. The homogeneous mixture is drawn into the cylinders, compressed and burnt in the usual manner after passing through the mixing valve.

Regulation of the fuel is by a float chamber supplying a small standpipe having a normal level slightly below the top of the pipe. The amount of kerosene entering the vaporizer may be termed to be automatically regulated in that it is proportionate to the opening of the throttle or vacuum created by the motor.

Changes in the temperature due to varying motor speeds are compensated for by the heat absorbing material. At high ratios the metal pieces hold the heat in reserve, while at low ratios it is given off more freely, and retaining as it does the high temperature for a considerable length of time, it is possible to start on the heavy fuel. It is held to be possible to start the motor after it has been inoperative for as long a time as two hours.

The G. C. is not designed to permit of starting the motor when the latter is cold. The conventional carburetor and gasoline are utilized until the vaporizer becomes warm—usually after the machine has been run a mile—after which the kerosene is employed. The volume of heavy fuel mixture passing to the cylinders is regulated by a throttle incorporated with the air mixing valve. To simplify the bi-fuel control the or-

dinary carburetor level is actuated by the hand member on the wheel and the kerosene mixture regulated by the accelerator.

The adjustments of the air mixing valve and float member are simple. If the motor shows signs of smoking on a full charge the screw A is moved in the direction of d. If it backfires the screw is rotated in the direction of c. Adjustment for low speed is secured by the screw B, this being moved in the direction of a for smoking and of b for backfiring. Further adjustment is provided by moving the screw E of the float member in the direction of e and f, for smoking and backfiring respectively. After one proper adjustment it is claimed that the vaporizer will not require any further attention other than filtering of the fuel.

It is stated that there is a considerable reduction in the fuel consumption, this running as high as 30 per cent. in some instances. There is also a corresponding saving in lubricating oil due to the saturation of the kerosene vapors by light oils, and an instance is quoted in which a truck operated 4000 miles

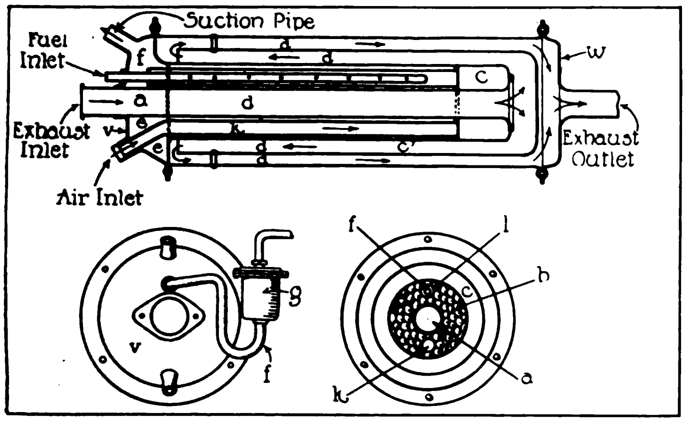

Fig. 2—Longitudinal Section of G. C. Vaporizer, End View and Section; a, c, Accumulator Jackets; b, Heat Accumulating Bodies; d, Exhaust Expanding Room; e, Gas Room; f, Perforated Tube; g, Kerosene Pipe; k, Air Pipe; l, Kerosene Pipe Protector; v, Front Cover; w, Back Cover.

with the vaporizer without sooting the plugs, valves, etc.

The use of other fuels than kerosene is possible; in fact the G. C. has been operated abroad on alcohol, ordinary methylated spirit, heavy petroleum, etc. Although new to this country the vaporizer has been successfully employed in England for about two years and in addition to being adapted to mechanical transports may be utilized on lighter vehicles. Aside from fitting a simple tee to the manifold to allow the kerosene mixture to reach the cylinders the utilization of the G. C. vaporizer does not involve any changes in the design or construction of the power plant.

The city of Huntington, Ind., has declined to grant a franchise for a street car line and has substituted in its place a motor omnibus service under a 20-year franchise. Huntington is the first American city to adopt motor 'buses to the absolute exclusion of street cars. Four machines for this service have been built by the White Company, Cleveland, O., the manufacturer of White trucks.

SUPPLANT RAILROAD SERVICE.

Large New York Grocery House Finds Garford Trucks Superior for Delivery Work.

The superintendent of delivery for the house of James Butler, New York City, one of the largest in the grocery business, recently stated that the company would never use the railroads again as the motor trucks had beaten them at every turn. Mr. Butler was one of the first business men in the United States to recognize the value of the mechanical transport, according to the superintendent. In 1909 he began, cautiously, to experiment with the motor propelled delivery wagon in comparison with the methods he then employed. A few weeks only were necessary to convince him that from an economic standpoint the horse had outlived its usefulness.

Mr. Butler's determination to discontine the use of railroads in transporting goods from his New York warehouse to the several score retail stores he maintains in New York, New Jersey and on Long Island, some of them 50 miles from the base of supplies, came when his latest order of Garford trucks, made by the Garford Company, Elyria, O., was delivered. The company now operates 16 Garford trucks, five five-ton, one two-ton and 11 one-ton machines, which have been found to be more efficient and economical than either freight or express service. Two of the lighter machines are used in special delivery work to the metropolitan branches, besides being called upon frequently to handle shipments of butter, eggs and vegetables to the suburban branches.

CO-OPERATIVE DELIVERY SYSTEM.

Three Merchants in Minneapolis Adopt This Plan, Utilizing Six KisselKar Trucks.

Now that motor delivery is a demonstrated success, merchants in several cities are using it on the cooperative plan. In Minneapolis, Minn., three of the leading concerns have a central clearing and routing station and use six KisselKar trucks, made by the Kissel Motor Car Company, Hartford, Wis., in making collections and deliveries. One of these machines makes five calls daily at each of the stores, collects the packages and takes them to the garage.

There they are sorted and assigned to the five remaining cars, each one of which makes three trips daily. The cars are each manned by a neatly uniformed driver and assistant. It is stated that the cost for delivery is about one-half that of horse haulage.

The Ritter Cigar Company of Detroit has a KisselKar truck, made by the Kissel Motor Car Company, Hartford, Wis., which in more than a year's running has not cost $1 for repairs. The operating expense of this truck, according to President H. G. Ritter, has been confined to fuel, lubricants and driver's wages.

NEW CHASSIS CONSTRUCTION DETAILS.

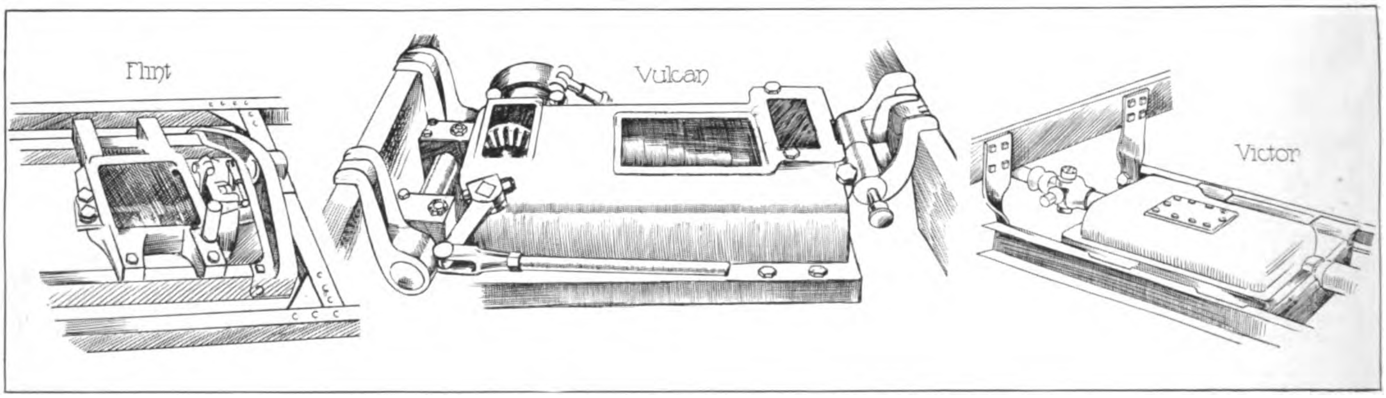
How Designers Have Improved the Suspension of Gear Boxes, Developed Torque and Radius Rods, Brakes, Mudguard Brackets, Springs and Shock Absorbers.

CAREFUL observation of the constructional details of differing motor vehicles shows that the engineers have given attention to what may appear to be factors of minor importance, and there are those who may assume that these are inconsequential in development. While it is true that no design is free from criticism when endeavor is made to combine every desired quality, and to eliminate every possibility, there is no doubt whatever that perfection of whatever may evidence the possibility of improvement generally means the strengthening of the weakest link. The items of fuel and tire expense prompt the elimination of weight through the use of better material or changed construction, and the cost of maintenance and depreciation impels a large factor of safety and the increase of wearing surfaces of moving parts. Protection of areas in frictional contact against abrasive wear, the reduction of vibratory stresses, the improvement of lubrication, making provision for adjustment and compensation for wear, the better alignment of linkage, minimizing strains from distortion, simplification of form and the reduction of production cost are some of the objects sought by the men who study vehicles constantly and in every form of service.

The protection of the transmission gearset against stress of chassis distortion, when it is not incorporated with the power plant unit, has been studied by practically every vehicle designer. One of the reasons for combination with the motor and clutch is minimizing the strains resultant from road shock, and with the assembly carried in a sub-frame varying constructions have been utilized to reduce vibration. Where the gearset is a separate unit and is located between the jackshaft and clutch, or between the clutch and rear axle, the proportions of the chassis frame are of much importance.

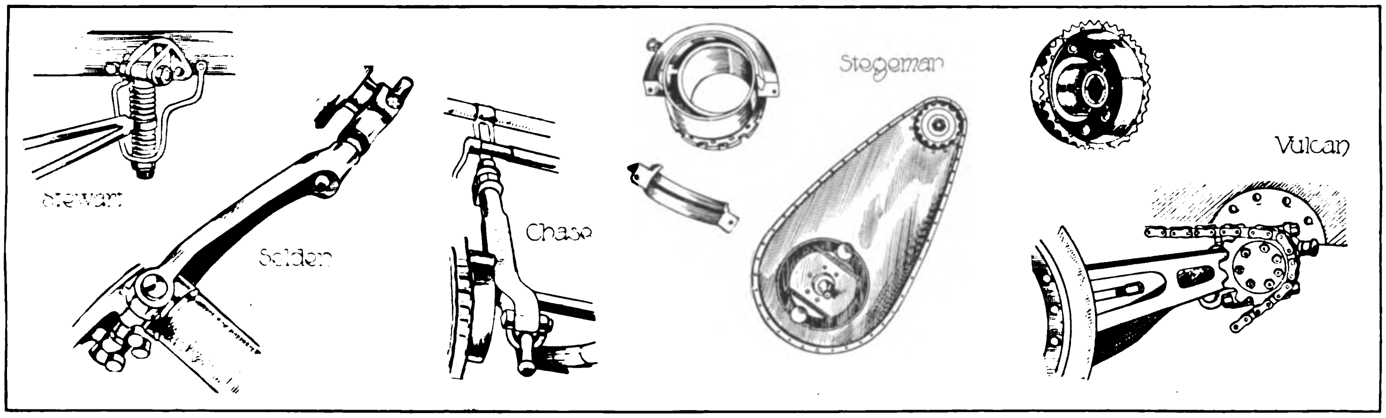
The purpose of many designers is to suspend the gearset or the sub-frame at three points, and an example of this may be noted in the Flint delivery wagon, which is shaft driven. The motor, clutch and gearset are carried in a sub-frame, the forward end of which is supported at the front end of the chassis at either side of the frame. The rear cross member of the frame, however, is curved, and is a sturdy channel section. In the centre of this member is a trunnion that is mounted in a bracket carried on the centre chassis frame cross member, there being a liberal bearing for the trunnion. The gearset is close to the end of the sub-frame and is carried on four supporting arms. Any movement of the side members of the chassis frame does not affect the gearset.

The design of the seven-ton Vulcan truck chassis gearset installation is another adaptation of the three point support. This case is in combination with the jackshaft, differential and gears, which are housed at the after end. The housing is very large and heavy, and it is in two sections, the upper having three cover plates, which may be removed for inspection or work. The forward end of the case is supported by a single bracket in the centre of a frame cross member, and at the rear it is carried on a shaft that extends through two arms forming a yoke, and two large lugs at the extreme end of the case. The rear yoke arms are secured to a chassis frame cross member. The transmission brake drums are at either side of the gearset case, inside the frame, and one of these is shown in the accompanying drawing. Another form of construction is seen in the Victor truck, where the transmission gearset is carried in a special sub-frame, this consisting of two side members of angle steel supported at either end by heavy steel straps twisted to permit easy riveting. On this frame the gearset case is carried by four long flanges at the sides of the case.



The Rear Sub-Frame Suspension of the Flint Wagon, the Three Point Support of the Vulcan Truck Gearset Case, and the Victor Gearset Installation.

The support of the forward end of the skeleton torque rod of the Stewart delivery wagon is a bracket on a frame cross member, lugs and a bolt holding the upper end of a guide for the rod, which is installed between helical springs. The lower end of the guide



The Torque Rod of the Stewart Delivery Wagon, the Selden Radius Rod, the Chase Radius Rod and Spring Support, the Stegeman Combined Chain Case and Radius Rod, and the Vulcan Radius Rod Adjustment.

carries a collar retained by a nut, and the relation of this guide is preserved by a forged yoke, the ends of which are riveted to the frame member, at either side of the bracket. While very light, the design is extremely strong and serves every purpose.

The radius rod of the Selden delivery wagon is of unusual design in that it is curved slightly to a point about a third of the length from the forward end, where there is an offset. The forward section of the rod carries a spherical bearing that encompasses the jackshaft housing, and on which it is free to move. The two sections of the rod are coupled by a right and left screw threaded into them. The rear end of the rod is clamped to the rear axle, on which it is free to move in a horizontal plane, while the spherical bearing at the forward end compensates the chassis distortion and maintains the relation of the axle. Ample provision for lubrication is made.

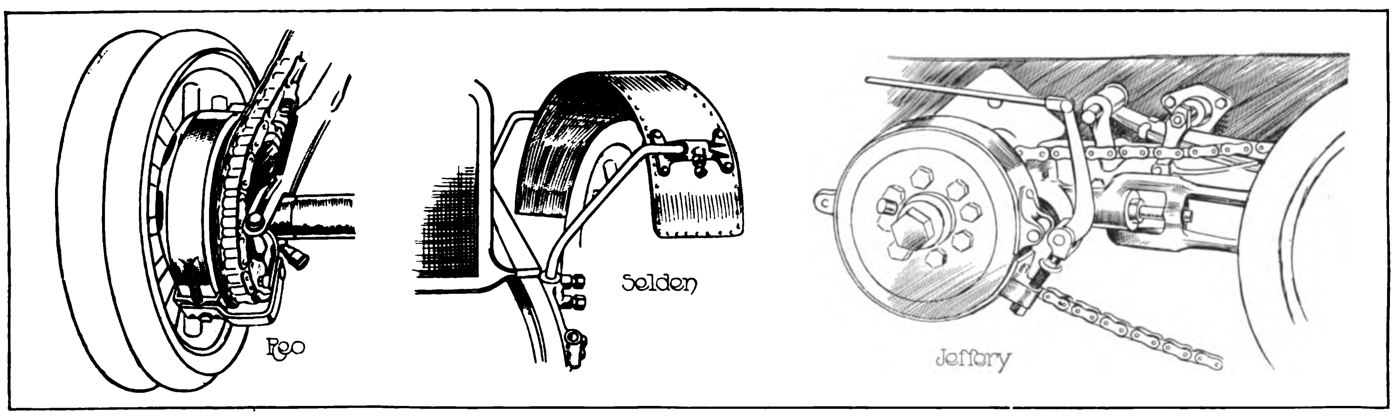
The radius rod of the 500-pound Chase wagon is designed so that it is mounted to move freely on the rear axle, the forward end being connected with the chassis frame. From the bearing on the axle the rod is curved upward, and the rear end carries a shackle in which the end of the rear cross spring of the vehicle is hung.

The chain case is made to serve as a radius rod in Stegeman wagons and trucks. The case is of pressed steel with an aluminum cover plate secured by cap screws. The case carries the shoes of the internal expanding brake, taking the place of the flange usually mounted on the rear axle, and the forward end is supported by an eccentric spherical bearing on the jackshaft housing by which adjustment may be made. The driving shaft sprockets are outside of the eccentrics. The eccentrics may be adjusted without removing the covers of the chain cases. The combination saves weight, insures the correct relation of the rear axle, and affords the fullest protection to the brake, chains and sprockets. The cover plates have inspection holes at the forward ends, through which lubricant may be introduced as desired.

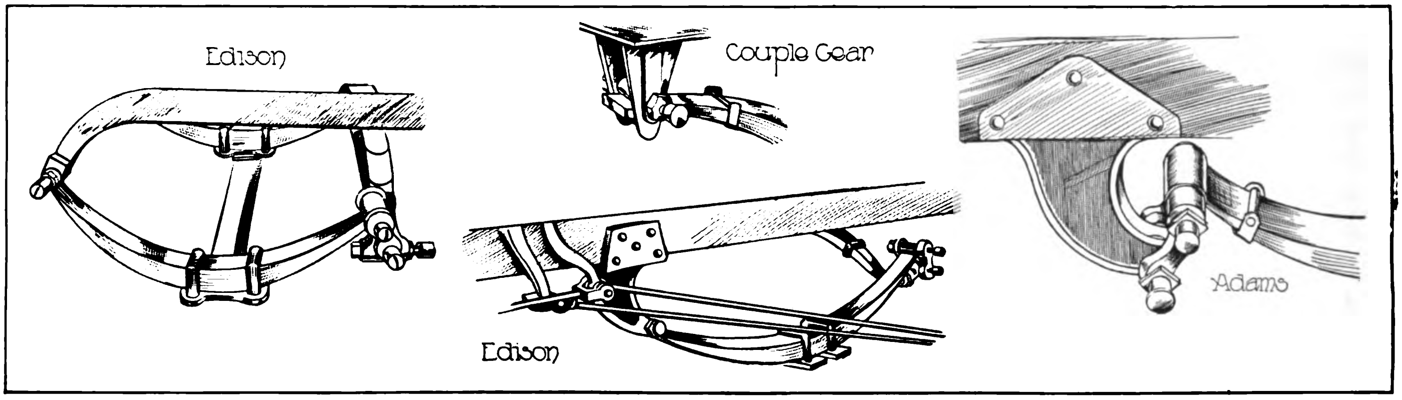
The radius rods of the Vulcan wagons and trucks are unusual in design in that the adjustment is made at the rear end by a rod that is threaded in the cross webs of the skeleton casting. This rod bears at the centre of the forward section of the bearing about the rear axle. The forward end of the rod is coupled to the jackshaft, on which it has a vertical movement, and there is horizontal movement provided for at the rear end. The end of the adjusting rod is squared to take a wrench, and the rod is held by a check nut.

The emergency brake of the Reo 4000-pound delivery wagon is the external contracting type, the bands encompassing drums 17 inches diameter and two inches wide on the rear wheels. Inside of this brake drum the rear sprocket is mounted on the wheel, and the sprocket is slightly smaller than the brake drum so that when it is desired to remove the wheel the sprocket may be drawn through the brake band without difficulty.

The manner in which the mudguards of the Selden



The Sprocket of the Reo Wagon That Can Be Drawn Through a Brake Band, the Mudguard Bracket of the Selden Wagon and the Grouped Brake, Spring and Radius Rod Connections of the Jeffery Wagon.



The Forward Platform Spring of the Edison Electric Wagon and the Method of Driving Through the Rear Side Spring, the Couple-Gear Spring Hanger and the Adams Rear Spring Connection.

delivery wagon are mounted makes for extreme accessibility. The brackets are carried higher above the frame than with the usual construction, and on the guards are riveted cast sockets. The ends of the brackets fit the sockets and are clamped by set screws. By loosening two screws a guard can be removed in a minute of time.

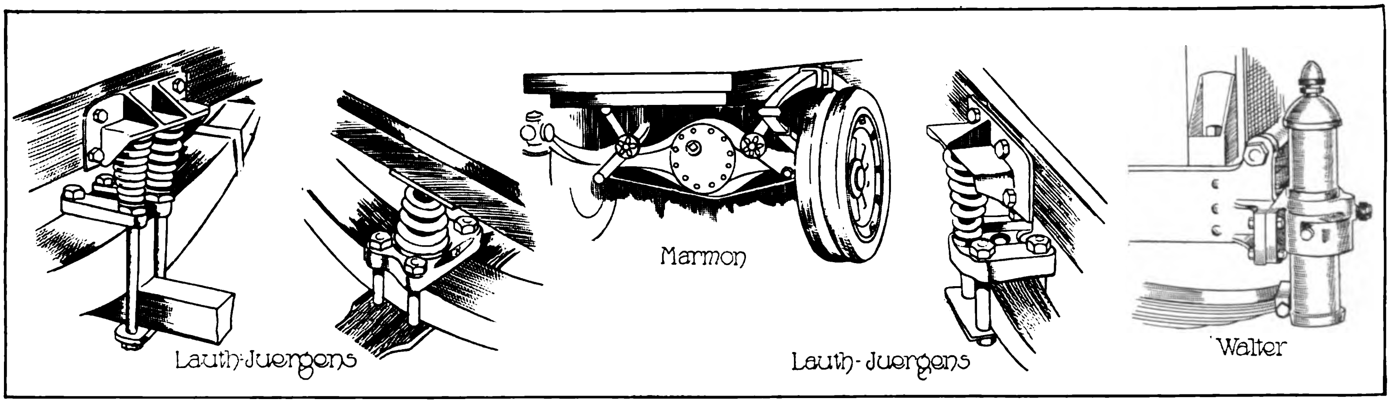
In the Jeffery one-ton delivery wagon much attention was given in the designing to minimizing the labor necessary in care and maintenance, and this is shown in the combination illustrated, where the forward spring hanger and shackle, the emergency brake shaft and draw rod, the radius rod adjustment and forward end coupling and the service brake on the jackshaft are so grouped that any of them can be adjusted or given any other attention almost instantly.

A novelty in spring suspension is the use of the platform construction for both the front and rear axles of the 1500-pound Edison electric wagon. In this wagon the spring horns are sharply curved downward and the arc of the semi-elliptic side springs is more pronounced than is usually noted in such members. The reason, however, is to bring the rear ends high, and from these to carry the shackles that couple the cross spring, which has approximately the same arc as the side springs. The rear spring construction is also unusual in that there are no radius rods and the drive is through the springs. These are bolted to the spring hanger, which has a shape that closely conforms to the arc of the spring. A large grease cup lubricates each bolt. There is a torque arm from the differential housing of the full floating rear axle to a frame cross member beside the motor, the drive being by worm and gear. It will be noted that both brake rods are outside the frame, where they are easily accessible.

The forward end of the heavy front spring of an Eldridge or Couple-Gear truck is mounted in a hanger where the weight is carried on a roll and spindle through the hanger, this permitting free longitudinal movement of the spring and yet having all of the driving strain sustained by the whole spring, and not by the master leaf. The construction of the forward hangers of the rear springs in the Adams machines is exceedingly heavy and the form is intended to afford easy movement without severe stress. Both shackle bolts and the eyes of the hanger and spring are lubricated by grease cups.

In the Lauth-Juergens wagons and trucks the auxiliary springs are of the helical type. These are coiled in cone shape and for the trucks two are used for each rear spring. The springs are installed with the small ends mounted on extensions of the bolts retaining the outside ends of the spring saddles, and the upper ends are in contact with a hood bracket fixed to the frame. With the delivery wagons one spring is similarly used at the rear springs. For the trucks one spring is used forward, but with the delivery wagon a single spring is fitted with the base of the cone secured to the spring saddle and the upper end contracting against the side member of the chassis frame.

The Marmon light delivery wagon has a well known shock absorber installed between the axle and



Some Examples of Minimising Spring Stress: The Lauth-Juergens Helical Auxiliary Springs for Wagons and Trucks, the Friction Shock Absorber of the Marmon Wagon and the Pneumatic Shock Absorber of the Walter Truck.

the chassis frame by special sittings, the absorbers having a transverse instead of a longitudinal movement. The Walter trucks are equipped with Westinghouse pneumatic shock absorbers fitted between the forward ends of the springs and the chassis frame, the installation making a novel appearance. The result is said to be very satisfactory.

ELECTRIC MEN HEAR LABOR'S VIEW.

Attitude of Union Drivers Toward Motorized Equipment Stated by General Organizer.

The attitude of labor, as represented by the Teamsters' Union, was reflected at a meeting of the Electric Vehicle Association of America held in New York the evening of April 22, when a paper prepared by Daniel J. Tobin, general president of the International Brotherhood of Teamsters & Chauffeurs of America, was read by William H. Ashton, general organizer of the brotherhood. The meeting was presided over by Arthur Williams, president of the association, who stated that there were today opportunities for 46,000 men as drivers in this country, and that before the end of the year this number would be increased to 50,000.

The membership of the brotherhood was stated as 62,000, and it was emphasized in the paper that there was no controversy so far as the members were concerned in the use of motorized equipment. To the contrary there was several times reiteration that the union realized that commercial and industrial progress made the motor vehicle necessary, and the members who were drivers found that there was a decided betterment of conditions where the machines were used. The statement was made that the union men made the best drivers because they had experience with traffic and handling loads; that they were not opposed to doing other work outside of the operation of the vehicles; that as a rule they are men who have realization of their responsibilities and are practical and care taking in their work.

It was maintained that "In our particular trade or calling our employers are breaking in their drivers or employees and transferring them from the horse-drawn vehicle to the motor vehicle. Ninety per cent. of our chauffeurs in every city and town who are members of our organization were formerly teamsters or drivers. They have been transferred from the wagon to the automobile. They are doing the same work as they were doing formerly. We are thoroughly satisfied with the change and our work in nearly every instance is becoming easier. For instance, on Sunday morning, we have no stable work to do. We can stay with our family and the horses do not have to be cared for. This applies also in inclement weather and to the very warm weather. The driver does not need to worry when going up hill about the strain on his horses if he is driving a motor vehicle. The advantages obtained from the change are too numerous to mention herein."

Another phase was developed when the paper stated that:

"When the motor vehicle was first introduced into our American lives it became a fad for the riff-raff and good-for-nothing individuals who hang around the street corners, to become chauffeurs; men who had no knowledge or judgment as to space, location, etc. Because such a class was willing to offer its services for practically nothing, employers foolishly believed they were saving money by employing this class, but the intelligent individual or employer who understands anything about commercial life knew that it was cheaper to hire a man of judgment and understanding, who has the responsibility of a home and family, who is clean in life and healthy in body and mind, than to employ a careless individual in the operation of a motor vehicle." With reference to the belief that the union opposed the use of trucks and wagons, it was maintained that the general policy of labor was to recognize that the use of machines increased labor instead of reducing it.

During the discussion that followed the paper it was developed that in New York at least there was a jurisdictional controversy between the brotherhood and the Brewery Drivers' Union, and as both are affiliated with the American Federation of Labor and there had been no determination of the difference, the interests of each organization are controlled by it. This fact was developed from the statement that there had been difficulty experienced by one man at least in selling brewery trucks from the fact that the brewery drivers required two men on each machine and would not permit the driver to assist in loading or unloading.

It was explained by the reader of the paper that the brotherhood was directly interested in the progression of its members, and he stated that the local unions of New York, Chicago, Boston and perhaps elsewhere, had purchased trucks for the purpose of teaching members to operate them, so that they would be capable of driving machines in the event of the change of equipment by their employers. This statement resulted in the educational committee of the association being instructed to assist the union in the development of its members as drivers in any manner that would be practical and beneficial.

Edgar T. Ward, for years president of Edgar T. Ward & Sons, dealer in steel at 23-25 Purchase street, Boston, has retired from active participation in the affairs of the company, which will be continued by his two sons, John and Edgar Ward, under the firm name of Edgar T. Ward's Sons. He has also retired as president of the Union Twist Drill Company, Athol, Mass. He was presented a silver loving cup at a banquet given in his honor at Young's Hotel, Boston, by the officers and salesmen of the company of which he was so long the head, and of the George Nash Company, New York, N. Y., and Chicago, Ill., and of Field & Co., Philadelphia, in recognition of his eminent success as a dealer in metals.

BETTER WORK AT LESS COST.

Forth Worth, Tex., Gas Company Profits by Use of Commerce Wagons.

The Fort Worth Gas Company, Fort Worth, Tex., has in service two Commerce motor wagons, made by the Commerce Motor Car Company, Detroit, the first of which was purchased through a display made at the Dallas fair last October, and was delivered and placed in commission Nov. 7, and the second was delivered Feb. 6 of the present year. Fort Worth and its suburbs are a community with a population of more than 100,000 and it covers a considerable area. The work of the company is widely extended and it is constantly increasing. The first machine was a model C chassis with a panel body, which was placed in service in the meter setting department, where it displaced a two-horse team and wagon and a single horse and wagon. With the installation of the vehicle it was found that the services of two men could be dispensed with.

Commerce Model C Wagon in the Meter Department of the Fort Worth, Tex., Gas Company, Saving $91.65 a Month as Compared with Horse Work.

Careful observation was made and accurate record kept of the work and the cost when the change was made, comparison being made with previous expense for the department, and it was found that doing the same work and doing it better the net saving was $91.65 a month. During the period of observation, to April 18 of this year, the mechanical expense for the machine was $3.75, the cost of replacing a fiber ring Feb. 16. The record of the machine shows that it has been driven an average of 37.2 miles each working day with a monthly expense for oil and fuel of $9.50.

The result of the use of the model C was that a model A machine, equipped with an open express body, was purchased, and this was worked in the service department. When equipped, including the weight of the men and tools, the wagon weighed about 3000 pounds. This wagon has been driven an average of 25 miles each working day, and the fuel expense thus far has been $11.50 a month. The additional weight carried and that the service work is generally in sections of the city where the streets are unpaved are the reasons for the greater cost for gasoline and oil. The two wagons are doing the work for which five horses were used, and there is a considerable saving and the work is better and more rapidly accomplished.

NEW WORM DRIVEN MODEL.

Company Formed in California to Produce Machines Designed by Joslyn and Walton.

The Los Angeles Motor Truck Manufacturing Company, Los Angeles, Cal., has been formed to build a new type of motor truck, with underslung chassis, with a low centre of gravity and loading platform 21 inches above the ground, but having 11 inches road clearance. The company has purchased a 30-acre tract of land at Bangle Station, near Wilmington, Cal., Los Angeles harbor. Plans are being drawn for five large, reinforced concrete buildings, which will cost, together with machinery, materials, etc., over $300,000. About 250 men will be employed.

W. B. Joslyn, E. E., A. E., who has been connected with the automobile industry practically from its inception, and who for several years was in charge of the experimental department of the Studebaker Corporation, Detroit, maker of Studebaker commercial and pleasure vehicles, is vice president and general manager of the company. Mr. Joslyn and M. S. Walton, M. E., A. E., a designer of many years' experience, have worked out the new type of truck. The drive is by worm with all parts housed and protected so as to be dirt and dust proof.

The Spokane Grain Company, Spokane, Wash., recently replaced several of its horse delivery trucks with a five-ton Garford motor truck, made by the Garford Company, Elyria, O., having found the operation of the latter vehicle a considerable saving over its former methods. The truck covers more ground and does more delivery work than horses.

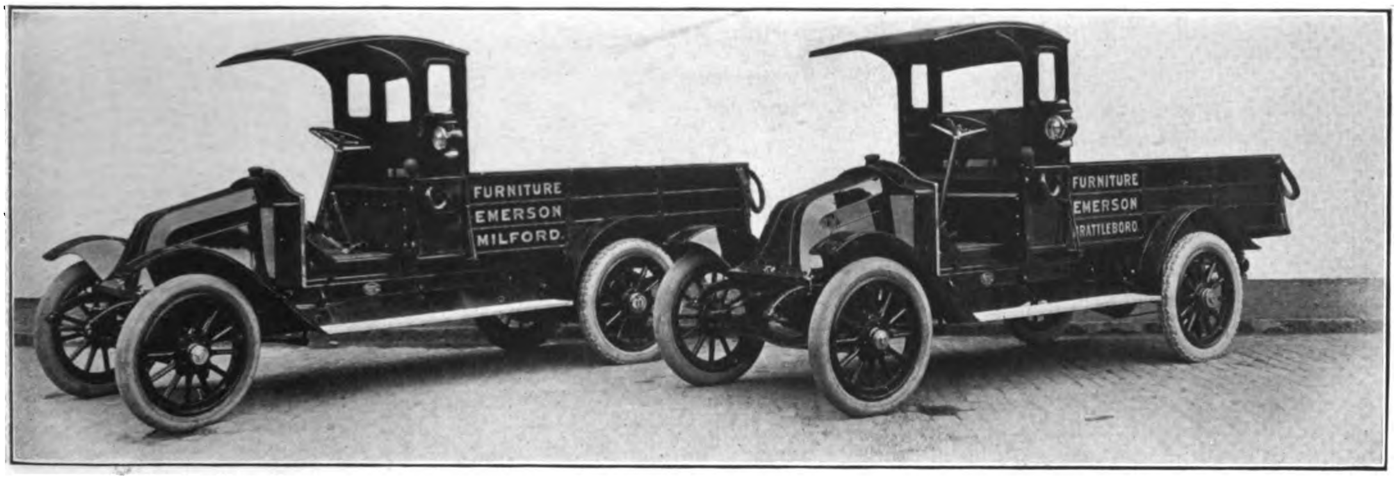
Charles E. Grace, manager of the White Motor Company, which is the Baltimore, Md., branch of the White Company, Cleveland, O., has been notified of the purchase of 15 trucks by the Atlantic Ice & Coal Corporation of Atlanta, Ga. The order calls for immediate delivery of the machines of three different capacities, 1.5, three and five tons.

STEWART 1500-POUND DELIVERY WAGON.

THE policy of concentrating its entire endeavors in the production of a single type of chassis which would be adapted to very widely differing service, has been followed consistently by the Stewart Motor Corporation, Buffalo, N. Y., maker of the Stewart delivery wagon. In keeping with this is the purpose to build as high a grade machine as is possible for a price that will appeal to those who desire a thoroughly dependable vehicle. The capacity has been fixed at 1500 pounds, and the speed permitted is proportionate to the load and the construction of the chassis. The head of the corporation is T. R. Lippard, president and manager, and R. G. Stewart is vice president and engineer, both having had long experience in motor manufacturing. The corporation will not build different types, but has standardized its vehicles and it is intended to continue the one chassis until the possibility of improvement shall be realized, and changes made will be without reference to seasons or years. units, and the design is such that any one group may be removed without dismantling or removing the others.

The motor is a Continental product, of the vertical L head, four-cylinder, water-cooled type, with bore of 3.75 inches and stroke of 5.25 inches, this having a rating of 22.5 horsepower by the S. A. E. standard, but with the bore to stroke ratio of 1:1.40 the statement of the maker that it will develop 30 horsepower is in every way conservative. This motor is believed to be in every way sufficient for a vehicle of 1500 pounds capacity.

The cylinders are cast en bloc from a fine quality of gray iron, with the water jackets integral. The entire top of the block is open, this permitting the water spaces to be cleaned, insuring that there shall be no obstructions and that the water shall freely circulate. The block is completed by the installation of a large cover plate in which is incorporated the water outlet



Two Stewart Delivery Wagons, Built for the Emerson Furniture Company, Brattleboro and Milford, Vt., Fitted with Open Express Bodies and Special Drivers' Cabs.

The Stewart delivery wagon was designed to meet what was regarded as the greatest requirement of the market, and to be suited to practically all forms of service where comparatively high speed is absolutely necessary. The chassis is fitted with six types of standard body equipment by the company, these including panel, express, open box, special express, stake platform and undertakers' installation. The express body is provided with a top, the open box body has a cape top and the special express body a standing top and wire grating sides. The chassis are sold without body when desired, and the bodies cost from $125 to $550 additional.

To insure the character of service—continued operation being the most important—sought by the designer, extreme care was taken to have the mechanism of the vehicle extremely simple and as accessible as was possible, it being realized that in many instances care and attention is more or less dependent upon the time required for the work, so far as the operator is concerned. Another factor was the independence of the manifold, there being a channel that increases in depth from the rear to the front of the plate, in which the movement of the water is directed to the outlet. The plate is retained by a series of cap screws, a gasket making a water tight joint.

In the manufacture the cylinder block is first bored and aged to eliminate danger of casting strains, after which it is reamed to size and ground and polished. The pistons are of the same material as the cylinder casting. These are turned and carefully ground. The pistons are five inches length. They are grooved for four rings of the diagonally split eccentric type, the rings and grooves being ground to careful fit, and there are five oil grooves that insure a perfect distribution of lubricant on the walls of the cylinders. The pistons are weighed and balanced before fitting.

The crankcase is constructed of high grade nickel aluminum alloy, in two sections, the upper half having four supporting arms and carrying the main and camshaft bearings, and the lower section having an oil reservoir below the base, a transverse web dividing it.

In this web are four channels into which the big ends of the connecting rods sweep. There is a large outlet in the oil reservoir by which it may be cleaned. The lower section may be removed for examination of or work on the crank and camshafts, bearings, etc.

The crankshaft is a .35 to .45 carbon steel drop forging that has a tensile strength of 90,000 pounds to the square inch, that is carefully hardened, heat treated and ground. It is mounted on three main bearings, which are respectively 2.75, three and four inches length from front to rear, and the shaft is 1.75 inches length. The total bearing surface length is 9.75 inches. This shaft is flanged back of the rear main bearing to take end thrust and prevent undue wear on the bearings. The bearings are high grade nickel babbitt, and after these are fitted they are extended in special extension arbors and reamed and scraped by hand. They are retained by brass retaining screws.

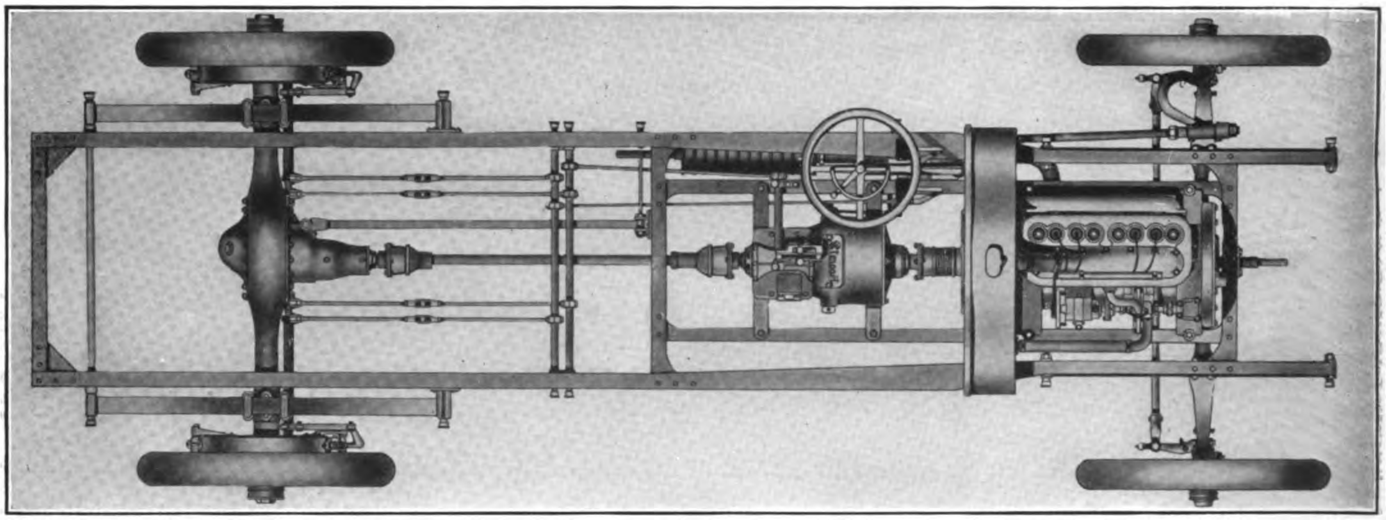
The connecting rods are drop forged steel I sections 10.5 inches length, and they are formed to carry big end bearings 2.5 inches length. The rods are heat treated to insure the greatest strength. The big end bearings are nickel babbitt, which are clamped by caps retained by nickel steel bolts and a special locking device. The bearings are fitted with steel shims, that they may be adjusted when worn, and similar provision has been made for the adjustment of the main bearings. The wristpins are of nickel steel and the generous bearings are of nickel babbitt. The camshaft is drop forged with the cams integral from a low carbon steel, and in making it is carefully ground, hardened and heat treated. The shaft is 1.0625 inches diameter and it is carried on three bearings, these being 2.3125, 1.5 and 1.25 inches length respectively from front to rear. These bearings are of nickel babbitt and are prepared as are the other principal journals of the motor. The design is such that the camshaft may be removed at the forward end of the motor by the removal of the cover of the timing gearcase.

The timing gears are contained in an extension of the crankcase and enclosed with a plate in the usual manner. The timing gears are large in size and wide of face, and are helically cut to prevent noise.

The valves have two-inch ports and the valve heads are of nickel steel, electrically welded to carbon steel stems. The ends of the stems are hardened to minimize wear. The valves are interchangeable. The valves and valve seats are accurately ground to size, there being sufficient clearance provided for to insure effective scavenging of the cylinders and the intake of ample charges of fresh fuel. The springs are large and well tempered. The valve tappets are chrome nickel steel and are mushroom type, being case hardened, and with heads and stems ground to size. The adjustment for wear is made by hardened screws and check nuts. The valve mechanism is enclosed in pockets that are enclosed with cover plates retained by wing nuts.

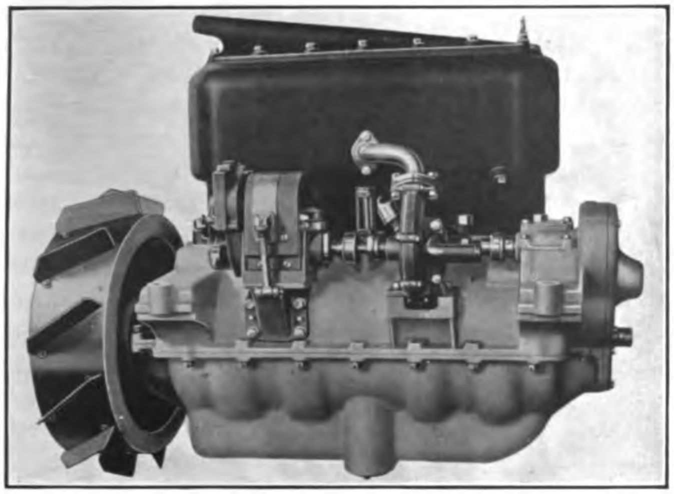
The intake manifold is integral with the cylinder block, there being a short riser by which the carburetor is connected. The exhaust manifold is a separate casting of conventional form.

The lubrication is effected by two plunger pumps that are actuated by an eccentric on the camshaft. The oil is drawn from a well in the reservoir, being filtered before entering the pumps, and is forced through a system of tubes to the rear main bearing and the timing gearcase. The drainage is into the pits or channels in the bottom of the crankcase, and the distribution to the crankshaft, camshaft and wristpin bearings, to the cams, tappets and piston and cylinder walls is by splash. Pockets accumulate sufficient oil to thoroughly lubricate the camshaft bearings at all times. The overflow of oil is carried to the reservoir, where it is filtered before it is again used.



Top View of the Stripped Chassis of the Stewart 1500-Pound Delivery Wagon.

The water is circulated by a centrifugal pump of large size that is driven by an outside shaft at the right side of the motor. The pump bearings are unusually large and the stuffing boxes are of proportions to insure long endurance. The radiator is a flat tube construction, but it has the appearance of a honeycomb design. It is mounted at the dash on helical springs to prevent damage from road shock and chassis distortion. The motor is covered with a hood of the Renault type, and the air is drawn through the radiator



The Right Side of the Motor of the Stewart Delivery Wagon Chassis.

by a series of blades carried on the periphery of the flywheel, and carried out under the floorboards. The ignition is by a high-tension magneto with a fixed spark, this eliminating a possibility of the motor being overloaded. It simplifies the system, minimizes the wiring leads, and insures against any complication. The carburetor is an automatic float feed type that will afford a satisfactory mixture under all conditions of operation.

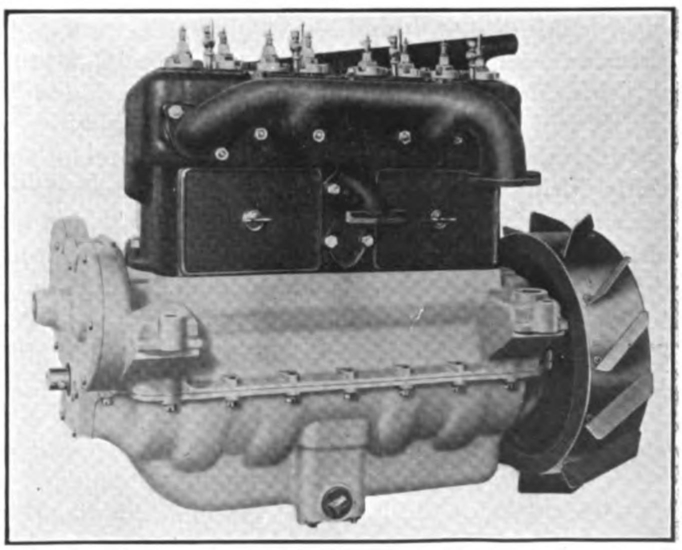
The clutch is a multiple disc design in which are 11 plates, nine inches diameter, five of which are faced either side with Raybestos and fitted between the other six. The clutch is positive and easy in its engagement, and it requires practically no attention. The clutch may be removed by taking off the front cover and removing the double universal joint between the flywheel and the clutch. The clutch case is integral with the transmission gearset case and it is a nickel aluminum alloy. The gearset is a Brown-Lipe construction that affords three forward speeds and reverse. The gears and shafts are large, of 3.5 per cent. nickel steel, double heat treated. The shafts are fitted with stuffing boxes to prevent leakage of oil and they are mounted on Timken bearings throughout.

The driving shaft is a high quality steel, 1.25 inches diameter, and there is a universal joint at either end to compensate for the changes in alignment from chassis distortion. The rear axle is a Timken construction of the full floating type, and it is carried in a pressed steel housing that is strengthened by a truss. The housing is reinforced by sleeves at either end which support the spring seats and carry the weight of the machine and its load at the wheels. The differential gears are large and are mounted on Timken bearings. The differential ratio is five to one. The front axle is a heavy I section. The pivots are fitted with Timken bearings, and this type of bearing is used with all wheel spindles. The tiebar, drag link and tail lever are steel drop forgings. They are installed behind the front axle for protection.

The frame is a high carbon steel channel section that is 4.5 inches deep at the centre and is tapered toward either end, with wide webs. This frame carries the sub-frame in which is mounted the motor and the transmission gearset, the supports of these units being designed to be easily removable if necessary. The frame is carried on semi-elliptic springs of special steel that is carefully heat treated. The forward springs are 38 inches length and two inches width and the rear springs are 50 inches length and 2.25 inches width.

The wheelbase is 126 inches and wheels are artillery type, 12 spokes, 1.625 inches diameter forward and 1.75 inches diameter rear. They are equipped with 34-inch tires, four inches forward and 4.5 inches rear, of the pneumatic type. The control is by the conventional pedals for the clutch and for the service brake, and the throttle lever is located on the steering column above the wheel. The steering wheel is at the left side. The steering gear is a worm gear construction with a worm of hardened steel, ground to size. The worm wheel is hardened steel, integral with the shaft. In this there is abundant provision made for adjustment in the event of wear. The gear changing lever and the emergency brake lever are located in the centre and are mounted above the transmission gearset case, being easily removable should there be need. The direct connection eliminates a number of parts. Two sets of brakes are installed, the service brake being internal contracting and the emergency brake external contracting in and on drums 17 inches diameter bolted to the rear wheels.

Much care has been taken to insure adjustment of the wearing parts and ample provision has been made to compensate for wear, which fact is evidenced by the use of high grade bearings, adjustable wherever necessary, and the construction of large surfaces wherever there is frictional contact. The same attention has been given to lubrication, all of the spring bolts being fitted with large grease cups, the pedal and brake shafts have grease cups outside of the frame where they are in every way accessible, and the steering gear is equally well lubricated. Wherever it is deemed necessary oil cups have been provided.



The Left Side of the Motor of the Stewart Delivery Wagon Chassis.

The standard bodies built by the company are designed with special reference to having the load well distributed, and these are suited for all ordinary purposes. The Stewart Motor Corporation has made very rapid progress since its organization and it is now building more than 50 machines a month. It is represented in 55 different cities and now has its vehicles in service from Edmonton, Alberta, to New Orleans, and from Seattle to Boston, besides having a very promising export business with various South American countries, where energetic agents are industriously exploiting them.

BUSINESS WAGON ACCESSORIES.

Chas. E. Miller Calls Attention to Some Specially Designed for This Use.

Chas. E. Miller, 97-103 Reade street, New York City, the pioneer accessory dealer, with branch stores in 15 cities and nine states, calls attention to the special fittings designed for service with motor business wagons. He suggests that this situation indicates the importance of this branch of the industry. He says:

"A few of these special fittings consist of anti-skid chains, such as the Federal, the Eureka and the Never-Skid. The first named is made with four bands, which fit almost completely around the tire and rim, and these bands are connected by chains on either side, the surface of the chain being shaped the same as the tire on either side so as not to injure the tire. The Eureka consists of a number of quadrilaterally shaped metal pieces connected by short chains so that the rough surfaces presented to the pavement have a cutting effect that resists side skidding. The Never-Skid is made for dual tires and has a series of frogs linked together, each frog being cast in the form of a cross, the central portion of which fits into the groove between the dual tires and prevents the chain from slipping off."

GEDDES SUCCEEDS KELLY.

President of Kelly-Springfield Motor Truck Company Retires on Account of Ill Health.

The many friends of E. S. Kelly, president of the Kelly-Springfield Motor Truck Company, Springfield, O., maker of Kelly trucks, will regret to learn that his health is such that he has felt compelled to retire from the active detailed management of the company. Mr. Kelly becomes chairman of the board of directors and will continue to exercise a general oversight over the affairs of the concern, but the details of the management will devolve upon James L. Geddes, who succeeds Mr. Kelly as president. He will be assisted by O. S. Kelly, who continues to be general manager.

The affairs of the company are in most excellent shape. The factory is running to its fullest capacity and the demand for the goods is sufficient to give every assurance of a prosperous future for the company. Mr. Kelly, while regretting his inability to continue as president, feels that he has secured a very competent successor in Mr. Geddes, who for many years was associated with Emerson McMillan, chairman of the board of the American Light & Traction Company, and who, with the firm of Emerson McMillan & Co., banker, holds a controlling interest in the truck company. Mr. Geddes has been connected with the Detroit City Gas Company for 14 years, joining its force in 1899, after a number of years with the Grand Trunk railroad in Port Huron, Mich., Detroit and Montreal, Can. His past business career has been such that the fullest confidence is felt as to his conduct of the truck concern.

Mr. Kelly was one of the pioneers in the rubber tire business. In 1894 he started the Kelly-Springfield Tire Company, which produced rubber tires for horse drawn vehicles. After promoting that company to a high production and financial efficiency, he retired from its board of directors and disposed of his stock. He remained inactive until about three years ago, when he purchased and reorganized the Frayer-Miller Motor Truck Company and began a campaign of development.

WINNIPEG MOTOR COMPETITION.

Annual Agricultural Contest at Canadian Industrial Exposition from July 1 to 16.

The annual agricultural motor competition in connection with the Canadian Industrial Exhibition will take place at Winnipeg, Manitoba, from July 1 to 16, and it is planned that it will be the largest and most interesting demonstration of efficiency to take place in Canada. All of the engines entered must be at the exhibition grounds the morning of July 1 and the first two days will be devoted to judging them for design and construction; July 3, 4, 5, 7 and 8 will be given over to brake tests, and July 10, 11 and 12 to plowing.

The classification will include three divisions, the first of which shall be for gasoline traction engines having a piston displacement of less than 300 cubic feet a minute, of more than 300 and not exceeding 500 cubic feet, and in excess of 500 cubic feet; the second will be for kerosene traction engines of the same classes with reference to piston displacement; the third will be for steam traction engines with piston area in square feet times 60 or less, from 60 to 100, and in excess of 100, the piston displacement to be the area of the piston in square feet times 700, which is established as the typical speed. In compound steam engines the high pressure shall be used and 10 per cent. added. The prizes will be gold, silver and bronze medals. All entries will be made on or before June 2. Competing machines must be stock construction and a blue print or photograph of a blue print of the boiler of steam engines must be approved by the Alberta inspector and accompany the entry.

THE SELDEN ONE-TON TRUCK.

THE accompanying illustration shows a Selden 2000-pound capacity delivery wagon in the service of Samuel Sloan & Co., Rochester, N. Y., a large dealer in plumbers' and steam fitters' supplies. This chassis is a regular stock production, with wheelbase of 145 inches. The body equipment was designed especially for the work required in the company's delivery, being heavily ironed inside and protected against damage and excessive wear resulting from the handling and haulage of large iron pipe and other heavy metal materials that would be particularly destructive to the ordinary unprotected wooden body.

The illustration shows the characteristics of the Selden machine, which include sturdy construction and extreme simplicity. The design was created to meet the exacting requirements of heavy haulage service, and all parts are constructed with unusually large factors of safety. Well established principles were not departed from, but endeavor was made to combine in a single machine every desirable quality and to have practical construction that is free from structural weakness and possible causes for failure.

The motor is a four-cylinder, water-cooled, L head vertical type, with bore of 3.75 inches and stroke of 5.25 inches, with the cylinders cast en bloc. The engine is rated at 22.5 horsepower by the S. A. E. rating, but it will deliver considerable in excess of this. The cylinder block is cast open and it is covered with a large plate secured by a series of cap screws. The water spaces are large and there is certainty of the motor being thoroughly cooled. The crankcase is a barrel type, with the upper section carrying the main and camshaft bearings, and the lower half includes the base and the oil reservoir, the latter being separated by a transverse web, in the upper side of which are the oil pits for the splash lubrication. The crankshaft, camshaft, connecting rods and timing gears are large and of high grade material. The bearings are of liberal proportions and designed for long endurance. The valve mechanism is protected against wear by being enclosed by plates secured by wing nuts that are readily removable.

The motor is cooled by a circulation of water, driven by a gear actuated pump of the centrifugal type, through a vertical tube radiator, and by a belt driven fan mounted on an adjustable bracket at the forward end of the construction. The lubrication is a force feed constant level system. The lubricant is drawn from the reservoir from a screened well by a plunger pump driven by an eccentric on the camshaft. It is forced through a system of tubes to the timing gears and the rear main bearing, and thence drains to the base of the crank chambers, where it is distributed by splash to all the moving parts of the engine. The excess from the crankcase is drained back to the reservoir. The ignition is by a high-tension magneto, with a battery of dry cells for starting and a reserve. The carburetor is an automatic float feed type that is said to give excellent results under any condition of operation.

The power plant is a unit construction in which the flywheel, clutch and transmission gearset are enclosed. The clutch is a multiple type with 13 steel discs, six of which are faced at either side with Raybestos and contact with the other seven plates. The clutch is operated without lubrication, and is extremely smooth in its engagement. The clutch is assembled with the transmission gearset, which is a selective construction, having three forward speeds and reverse.

A Selden 2000-Pound Delivery Wagon in the Service of Samuel Sloan & Co., Dealer in Plumbing and Steam Fitters' Supplies, Rochester, N. Y.

The gears and shafts, of nickel steel, heat treated, are of large size. The shafts are mounted on taper roller bearings throughout. The power plant is mounted in a sub-frame that protects it against the strains of chassis distortion.

The drive is by a driving shaft with a universal joint at the forward end to a jackshaft of the semi-floating type mounted in high duty roller bearings. The differential and driving gears are heavy and have an adjustment by a nut back of the thrust bearing. The drive shafts are a special alloy heat treated steel, 1.375 inches diameter. The jackshaft is supported in the frame on spherical bearings which compensate frame distortion. The drive to the rear wheels is by side chains. The frame is a steel channel section 5.625 inches width, .1875 inch thick, with wide webs. The front cross member is easily detachable with the radiator, so that the entire power plant may be removed in the event of need. The forward springs are 42 inches length and 2.25 inches width, and the rear springs

are 48 inches length and 2.5 inches width, all being semi-elliptic. The front axle is an I section and the rear axle a rectangular forging, both of heavy construction and heat treated. They are fitted with wheels shod with 36 by 3.5-inch tires forward and 36 by four-inch tires rear.

The drive is at the left side through a gear of the worm and nut type with an 18-inch hand wheel. The spark and throttle levers are under the steering wheel. The clutch and service brake are operated by pedals and change gear and emergency brake levers are at the centre, mounted on the transmission gearset case. The service brake is with internal expanding shoes operating within 10-inch drums with 1.75-inch faces on the jackshaft, and emergency brake shoes operate within 16-inch drums on the rear wheels. All brake shoes are faced with anti-friction material.

The motor is governed so that a speed of 16 miles an hour cannot be exceeded unless the seal is broken. The motor speed is 1150 revolutions a minute. The wheelbase is 125 or 145 inches. Grease cups are located wherever there is contact of moving parts and these are easily accessible. Bodies are stocked to meet the requirements of purchasers in different sizes and types suited to the two lengths of chassis.

The Selden plan of selling machines is a departure in the automobile industry, and it is meeting with large success. The Selden Truck Sales Company of Rochester, N. Y., was organized to provide the necessary financial resources to sell the vehicles on a time payment plan. This policy makes it possible for many reputable merchants and manufacturers to purchase who could not conveniently buy when a full cash payment is required upon delivery. This has opened a very large field for the sale of service wagons, for it affords a certain means for many prospective buyers to own machines without having to carry the financial burden that would be entailed by the immediate payment terms by which most wagons are sold. The Selden plan gives the purchaser a year in which to pay for a vehicle.

INTERESTING PEERLESS MACHINE.

Utilized for Transporting Vinegar in Large Quantities and Designed for Quick Service.

The Peerless five-ton truck, made by the Peerless Motor Car Company, Cleveland, O., and owned by Alart & McGuire of New York City, has the appearance of a water wagon. The firm requires in its business a great amount of vinegar, which is shipped to it in tank cars resembling those used to transport oil. The truck is used to carry the vinegar from the railroad yards to the works.

Quick loading is provided for by a centrifugal pump fitted to the vehicle by the firm's engineer. The truck is run alongside a tank car and the right rear wheel is jacked up so that it does not touch the ground. The mechanism of the pump is attached to this wheel by a belt. The hose is sunk in the tank car and the motor started. It turns the rear wheel over rapidly through the differential and 1153 gallons of vinegar, the capacity of the truck's tank, are pumped in 12 minutes.

The wheel is lowered and the load is transported to the works, the entire transaction taking about 20 minutes. At the receiving end the vinegar is run through a hose from the pipe in the bottom of the truck to another which extends from the sidewalk in front of the plant. It averages 45 miles a day and carries five loads of vinegar. The record haul for one week was 26,000 gallons. A float at the front end of the tank shows the height of the level of vinegar at all times.

WITH CONTINENTAL MOTOR.

A. H. Doolittle Leaves Thompson Agency to Take Charge of Advertising Campaign.

Albert H. Doolittle has been appointed advertising manager of the Continental Motor Manufacturing Company, Detroit and Muskegon, Mich., which is to inaugurate an extensive selling campaign. Mr. Doolittle is well known in the industry and goes to the Continental company from the staff of the J. Walter Thompson Advertising Agency of Detroit. It is understood that the Continental business will still be placed through the MacManus Company of Detroit and Toledo, O.

After studying mechanical engineering at Cornell University, Mr. Doolittle became a member of the engineering force of the Pope Manufacturing Company, Hartford, Conn., in 1904, for the experience that branch afforded. Less than a year later he entered the shops of the Electric Vehicle Company of that city for a thorough course in automobile building. There he went through every department of mechanical construction, assembling, testing, repairing, demonstrating, contest driving and selling, becoming assistant manager of the New York branch. In 1909 he made an extended motor tour of Europe, entering six countries and covering over 7000 miles. During this trip he crossed 17 of the highest passes in the Alps in an American car without trouble. He also visited a number of foreign factories and gained an insight into their methods.

Upon his return he entered the employ of the Knox Automobile Company, Springfield, Mass., and in six months became advertising manager. His copy was conceded to be of special value and his publicity stories were widely used. In this manner he was brought to the attention of the Journal Company of Troy, N. Y., where he aided in directing the advertising campaigns of various automobile concerns and became automobile editor of the Carriage Dealers' Journal. While engaged in special work for this company on behalf of a factory at Moline, Ill., he became associated with the Thompson agency.

THE BLAIR DIRECT DRIVEN TRUCKS.

THE Blair Manufacturing Company, Newark, O., which has an eastern office at 293 Northampton street, Boston, Mass., is building four sizes of worm driven wagons and trucks, these being 1.5, 2.5, 3.5 and five-ton capacities. These machines are the development of more than six years' experience and careful observation of the requirements for differing services, and are built to afford long endurance and constant use. The company began with the purpose of constructing vehicles that would be suited for practical transportation, and the designs were worked out with a knowledge of the hard use and excessive strains and stresses that a machine must be subjected to.

In the work a freight vehicle is expected to do, where it must be used with full load capacity as much of the time as is possible, and where the highways and streets cannot be chosen, it is not always practical for the most careful and skillful driver to favor it, and there are times when the greatest power must be exerted in tractive effort. When a vehicle is driven over rough streets and roads with a load the chassis is subjected to constant distortion, and the "weaving" of the frame causes stress that varies greatly. The rigid construction may result in eventual excessive wear, and the yielding design may bring about disalignment and the accompanying consequences.

Three objects were sought by the designer of the Blair machines, the one being the attainment of the highest efficiency from the power plant, the second the application of the driving effort where it would be extremely productive, and the third the protection of the wearing parts. But it was also desirable to have the mechanism of the vehicle in every way accessible, and to simplify the construction so as to minimize the time that would be necessary for making examination, adjustment and restoration. The design was intended for service, and with the realization of the duty probable large factors of safety were allowed, and the materials selected were those that would, because of quality, afford the necessary strength with a minimum of weight.

In the development of the design it was purposed to create what would be a standard, and from this to build in differing capacities, there being no variance save in proportions, each to have the same qualities and characteristics. The original size decided upon was continued for a considerable period before others were built, this being regarded as an experiment and the vehicles were very closely observed.

In the Blair chassis the endeavor has been to minimize the driving stresses and to reduce to the lowest practical point the strains from distortion, and this has been accomplished in a novel manner. The design is not in any sense experimental, for it has been tested for more than six years, and it has proven to be so important a factor that it has been patented. To illustrate the principle it may be well to instance what may be within the experience of many. Those who have ridden a bicycle understand how easily such a machine may be guided by grasping the handlebar close to the head, and how it may be pushed over obstructions of considerable height. Those familiar with boats know that one may be towed and that it will vary in direction according to the length of the tow rope, but it may be pushed along with a boat hook if the hook is forward of the centre of effort, so-called, and that as the hook is carried forward the control becomes more and more certain. If the hook is placed in the extreme bow it is possible to push the boat with the greatest degree of ease.

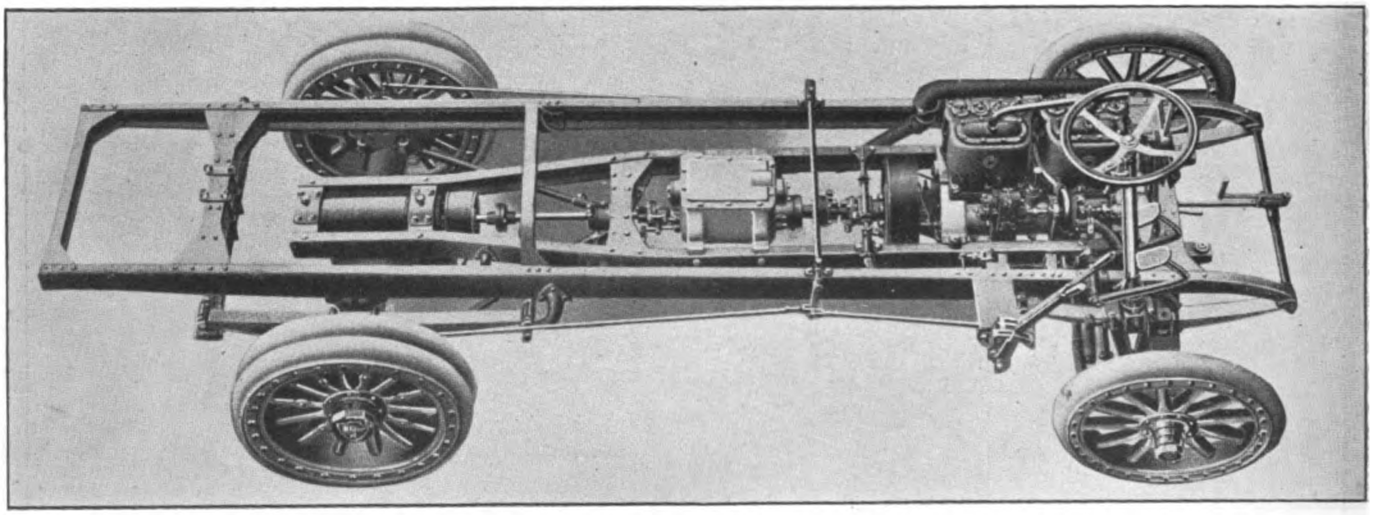
Blair 3000-Pound Direct Driven Delivery Wagon Equipped with an Open Express Body.

The design of the Blair machines is such that the driving effort is exerted directly above the forward axle, and this makes it possible to steer with the greatest ease. The wheels may be placed in a car track, for instance, and the vehicle will follow the track as though the tires were flanged. Instead of the driving thrust being directed upward through radius rods connected to the chassis frame back of the centre, or by a torsion member connected to a chassis cross frame member, in the Blair wagons and trucks the effort is directed in nearly a straight line from the rear axle to the front. This leaves the chassis free to float on the springs, and there is no undue strain brought on the mechanism by the weight of the load.

The result is surprising, because there are no universal joints in the driving shaft, which is carried in a straight line from the clutch to the rear axle, and there is no possibility of side pressure or thrust leverage, because the driving effort is directed through the frame carrying the shaft and mechanism, and it is so installed that the rear axle, no matter what the character of road shock, does not cause a strain. By reference to the chassis illustration it will be seen there is no connection between the chassis frame and the middle or subframe that will not yield to any movement without resistance. The middle frame is slightly longer than the wheelbase of the machine and it is constructed of very large steel channel section. There are four cross members, the one at the front end, the second about two-thirds of the length back, and from this member the frame is "necked" or narrowed with the remaining two members comparatively close to the rear end.

At the forward end of the frame, bolted to the cross member, are two brackets that have heavy yokes, through the arms of which are holes. Bolted to the chassis frame cross member are two brackets with lugs that fit between the yokes, and in which are holes. The brackets are steel castings. Through the holes are large pins of hardened and ground steel. This construction is in effect a hinge or joint, so that the sub-frame is free to move vertically in the joints independently of the chassis frame. The sub-frame carries the motor, which is mounted on side arms, and the transmission gearset case. Between the clutch and the gearset case, transversely on the sub-frame, is the shaft carrying the fork that operates the collar of the clutch. The clutch shaft is coupled to the main shaft of the gearset. The gearset is a selective type, with three forward speeds and reverse, and the case is carried by four arms that rest on the sub-frame. Back of this is the driving shaft, which is in turn coupled to the worm shaft.

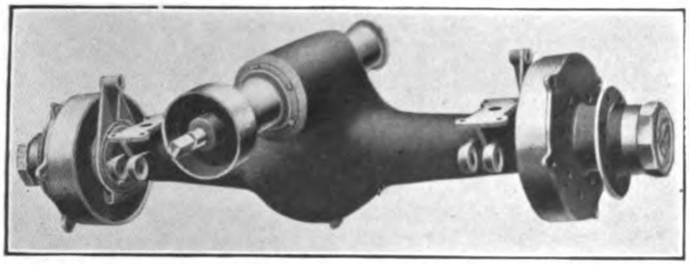
The rear axle housing is a steel casting and reference to an illustration will show its shape. Extending from the front and rear of the worm shaft case are heavy sleeves in which are the shaft bearings, the rear sleeve having a flange at its end. These sleeves are bolted to the axle housing. The worm shaft housing is installed between the ends of the side members of the sub-frame, and two members that are in effect collars are fitted around the sleeves. While the sleeves and collars closely contact, the wide bearing surfaces prevent any movement of the axle save vertically at either end. The collars are mounted on the subframe and it is against them that the driving thrust of the axle is exerted.



Blair 3000-Pound Chassis, Showing the Sub-Frame Carrying the Power Plant and Gearset, and the Means of Drive.

Under the spring seats of the rear axle are yokes into which are fitted the rear ends of distance rods. These rods may be moved vertically. The forward ends are mounted in a member carried in a swivel coupling under the second cross member of the subframe. These rods preserve the relation of the axle with reference to the sub-frame, but they do not resist any movement of the axle in a vertical direction at either end, the sleeves of the axle housing turning within the collars of the sub-frame. The movement of the axle, should either end be lifted by a road obstruction, does not affect the sub-frame, and the radius rods and the collars around the sleeves, while permitting free action, take all of the driving thrust.

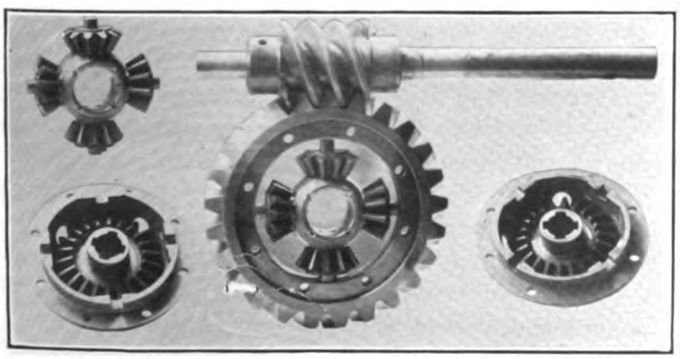
The motors are the well known Continental construction, they being four-cylinder, water-cooled types. These are in different sizes, in every instance there being abundant power. The 1.5-ton chassis has



The Blair Rear Axle Assembly, Illustrating the Rear Support of the Sub-Frame.

an engine with the cylinders cast en bloc with bore of 4.125 inches and stroke of 5.25 inches. The horsepower rating by the S. A. E. standard is 27.25, but it will develop considerably in excess of this. The motors for the 2.5 and 3.5-ton chassis are 4.5 inches bore and 5.5 inches stroke, which are rated by the same formula at 32.4 horsepower. These motors are designed for heavy duty, with a knowledge of the service that is required, and are built of highest quality material. The engines are cooled by a circulation of water driven by a centrifugal pump through a square tube honeycomb type radiator of unusually large size. The capacity of the cooling system is such that without the pump the engine would be kept at a satisfactory temperature under any circumstances by the thermo-syphon circulation.

The lubrication of the motors is by a force feed constant level system. The oil is contained in the base of the crankcase and by double plunger pumps it is forced through tube to the timing gears and the rear main bearing. The excess drains to the bottom of the crank chamber, forming pools into which the crank-pins and the connecting rod ends dip, affording splash lubrication for all other working parts. With these motors the valve mechanism is fully enclosed, and protected. The moving members of the engines are designed with large bearing surfaces and the shafts and gears are of such proportions that long endurance can be expected. The bearings are ample, the timing gears are helical cut to run noiselessly, and the provisions for adjustment include every part subjected to wear. The ignition is by a Bosch dual system, the spark being fixed. This insures a certain efficiency of operation under all conditions, and eliminates all possibility of the motor being abused, because it will pull until it is stopped through the weight of overload. The fuel supply is regulated by the usual hand throttle lever, the only control member on the wheel.



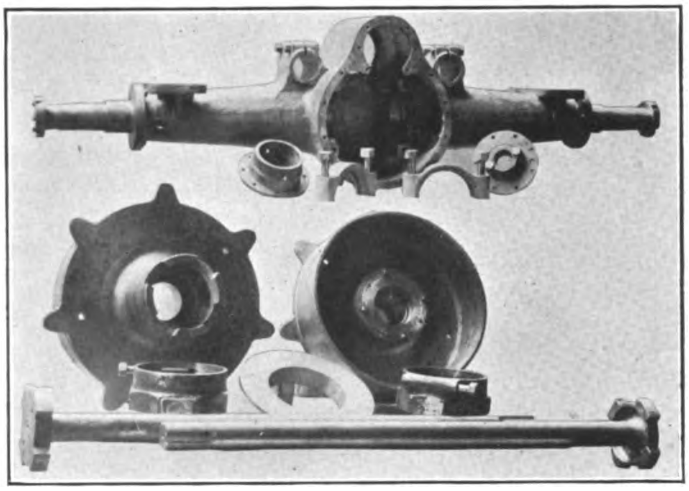
The Blair Worm, Gear Wheel and Differential.

The motor is installed at the forward end of the sub-frame and the flexible connections of the water circulation system provide for any movement of the sub-frame without strain or stress.

The carburetor is a special design of the automatic float feed type and the speed of the machines is regulated by a governor, 14 miles an hour being the limit allowed with the lighter vehicles.

The clutch is a large cone fitted with cork inserts, which insure against uneven or faulty action, and protect the engine against the strains when the machines are working under heavy load. The transmission gearset is mounted practically in the middle of the chassis and is conveniently reached through the opening in the floorboards. The transmission is so designed that all the change speed gears are constantly in mesh, being engaged with jaw clutches, but all the gears are idle when the motor is operated at high speed.

The construction of the rear axle is such that the weight of the car is carried on the ends of the housing, the driving shafts carrying clutches that engage with



The Blair Rear Axle Housing, Differential Bearings, Wheel Hubs and Driving Shafts and Clutches.

the flanges of the wheel hubs. There is no strain on the shafts. The differential gearing is exceedingly simple, the gear being mounted so that it may be adjusted or easily removed. There is a large drum mounted on the driving shaft on which the transmission brake contracts.

The chassis frame is mounted on semi-elliptic springs, the forward set, through which the driving effort is transmitted, being unusually large and strong. The rear springs are a platform construction, shackled forward and rear, so there is no restriction as to the movement of the frame. The front axle is an I section of drop forged steel of large size with unusually sturdy steering knuckles. The spring seats are forged integral. The tiebar and the drag link of the steering gear are located behind the axle to afford full protection against contact with road obstructions. The steering gear is a worm and nut type in which adjustment for lost motion can be made by loosening and tightening a single nut at the head of the housing. The emergency brake operates on drums on the rear wheels

and is a contracting band type. The brake rods, the clutch and transmission linkage are so connected that there is no strain whatever through the movement of the sub-frame.

The dash is installed directly behind the radiator and the engine is covered with a hood that rises above the floorboards back of the radiator. The seats are at either side, that for the driver at the right. The control is by the usual clutch and brake pedals and the levers for the change of gear ratios and the emergency brake are at the right of the driver. This construction makes it possible to examine the motor by lifting the hood without leaving the seats.

The wheel equipment is the usual artillery construction and they are 34 inches diameter with the lightest machine, and 36 inches diameter with the larger. The wheelbase of the 1.5 chassis is 114 inches, and of the 2.5 and 3.5 chassis 121 inches. The tire equipment is 34 by 4 inches single forward for the 1.5-ton type and 34 by 3 inches dual rear; 36 by 4 inches forward and 36 by 3.5 dual rear for the 2.5-ton, and 36 by 5 inches forward and 36 by 4 inches dual rear for the 3.5-ton chassis.

The equipment consists of the oil dash and tail lamps, horn and kit of tools. The chassis are fitted with standard stake platform or panel bodies, or special constructions may be built to meet the particular requirements of the individual purchaser.

NEW LIGHT DELIVERY ATLANTIC ELECTRIC.

THE Atlantic Vehicle Company, which has its executive offices and showrooms at 1600 Broadway, New York City, and its factory at Newark, N. J., has announced the production of the fifth model in the series of Atlantic electric wagons and trucks. The capacity of this machine is 1000 pounds, and is the smallest yet built, the other vehicles being rated at 2000, 4000, 7000 and 10,000 pounds. This model is now offered as a standard of the Atlantic line.

The Atlantic Vehicle Company builds high class vehicles, and it claims for its products extreme efficiency and mileage with reference to battery capacity. The quality of the Atlantic machines with reference to material and workmanship are well known to the service wagon industry and trade. The designs have been standardized and they represent extremely careful study of transportation needs and problems, as well as the best of engineering and the scientific determination of materials and proportions.

The Atlantic vehicles are designed with a view of affording the purchasers long and economical service under normal conditions of operation. While the quality of the materials permits comparatively light weight, there is a very large factor of safety with reference to every wearing part, and there has been extreme care taken to insure simplicity and accessibility that will minimize the labor and economize time so far as the care and attention necessary to efficient maintenance is concerned.

The 2000, 4000, 7000 and 10,000-pound machines are identical in every respect save proportions, the motor being suspended transversely in the frame, and the power being transmitted from the motor to the jackshaft by a single silent chain enclosed in an oil-tight case, and from the jackshaft to sprockets on the rear wheels by chains. The 1000-pound wagon, however, is a different design, the power being applied to a floating rear axle by the motor through reduction gearing, the motor and the axle being assembled practically as a single unit. This construction is considered to be especially simple and practical, affording high efficiency of power transmission and the fullest protection to the working parts, and requiring a minimum of care and attention.

The wagon is designed to have sufficient capacity to meet the requirements of those who desire a fast delivery service, and it has a very large mileage on a single battery charge. The general characteristics of the Atlantic design have been followed with such modifications as were necessary with the changed method of transmitting the power. The motor is a standard series wound construction that is suspended by a band encompassing it that has at either side a trunnion, these trunnions being carried in a yoke bracket that is secured to a cross member. The motor and the rear axle are coupled by a conical steel casting securedly bolted, and within this housing the shaft of the motor and the pinion shaft are connected by a sleeve that is clamped to the pinion shaft, having the necessary clearance for the motor shaft to permit end play and to eliminate the possibility of thrust upon the motor. The relation of the rear axle is preserved by radius rods and the vertical movement of the axle is compensated by the trunnions, on which the motor will move freely. There is no driving strain upon the motor. The lubrication of the axle and motor is provided for in the usual manner. Being in every way protected against the abrasive influences of dust, this construction insures minimized wear and efficient operation.

The other details of the chassis so far as practicable conform to the design of the other models, this being with reference to frame, spring, front axle, wheels and steering gear construction, the same high class materials being used throughout. The frame is a high grade steel channel section with generous cross members, which, with the electric furnace cast steel hangers, are hot riveted. The crucible steel castings conform to the S. A. E. specification; the drop forgings are a carbon steel to the same standard; the hand forgings are a manganese steel and the springs are Krupp silico manganese steel. All of these materials have the recommendation of the Society of Automobile Engineers, and are periodically tested by the Henry South

Engineering Laboratories that the standards shall be maintained. The quality of the steel is insured and such parts as are subjected to stresses are heat treated with extreme care.

The controller lever is mounted on the steering column and is connected with the controller under the toeboards, the controller being easily accessible. The combination service and charging switch is so located that the charging receptacle is dead during the operation of the vehicle. The machine is equipped with two brakes, both operating on the rear wheels, and both being actuated by pedals. The right brake pedal, that controls the service brake, with shoes expanding within large drums, is fitted with a ratchet and pawl for locking the brake. The left pedal operates the external contracting emergency brake bands on the wheel drums.

The battery cradle and compartment is another feature of the chassis. The doors of the box are divided in the centre and are hinged so that each door will swing 90 degrees, forming a shelf at the side when lowered. The battery cradle is mounted on eight travelling rollers that can be moved in guides, so that the trays can be drawn out half their length at either side, there being two stationary rollers on each, which maintain the level of the crates and facilitate handling. Six other rollers are so placed as to prevent the crates wedging in the compartment, insuring easy movement of the trays. This construction minimizes labor in examination of or work on the cells.

The provision made for the lubrication of the moving parts of the chassis is very complete, there being generous grease cups or oilers wherever necessary, and these are always accessible. The equipment of the chassis is complete, with the indicating instruments, switches, charging plug and cable, tools, etc.

ECONOMY IN HAULING MILK.

First Three Months of Service with Saurer Shows Saving of 46.7 Per Cent.

The problem of hauling large quantities of goods within a given time is pointed out as of great importance in the matter of handling perishable food products. The International Motor Company, New York City, has gathered data on the operation of motor trucks in the service of the Wa Wa farms, 18 miles from Philadelphia, Penn. These farms produce 5000 quarts of milk a day, which is delivered to customers in Philadelphia, Atlantic City and other resort towns in New Jersey. On account of its quality a large portion is consumed by babies, small children and persons not in good health. Formerly it was shipped by freight, which necessitated hauling to the local station by means of a three-horse team and again hauling from the Philadelphia milk depot or to Camden for reshipment, as the case might require.

It follows that the practicability of utilizing motor trucks was given careful consideration, and aside from the elimination of numerous handlings, the cost entered largely into the matter. During the first three months the 6.5-ton Saurer was in service it took the milk to West Philadelphia and Camden from the Wa Wa farms, collected the empty bottles and showed a saving of some 46.7 per cent. in haulage charges. Shipping by freight, including the maintenance of two three-horse teams, would have cost as follows: First month, $1078.24; second, $1135.20; third, $1131.87; total for three months, $3345.31. What it actually did cost, using the Saurer, was: First month, $486.01; second, $610.13; third, $686.66; total, $1782.80, representing a saving of $1562.51. The following tabulation is from figures supplied by Manager Stewart of the dairies:

Atlantic Delivery Wagon, One-Ton Capacity, with Panel Body, Used for the Service of A. Silz, Poultry and Game Dealer, New York City.

Truck travels 80 miles a day as follows:

	Miles
One round trip Wa Wa to Camden, N. J., 22 miles each way	44
One round trip Wa Wa to West Philadelphia, 18 miles each way	36
Total	80

Truck hauls 20 tons a day as follows:

Two loads bottled milk from Wa Wa, 6.5 tons each	13
Two loads empty bottles, one way each from Camden and West Philadelphia respectively, 3.5 tons to the load	7
Total	20

Average haul, 20 miles; average load, five tons.

Cost a day of operating, exclusive of depreciation, according to the owner's figures	$19.68
Cost a five-ton load hauled 20 miles	$4.92
Ton-miles a day	400
Cost a ton-mile	4.92c
Depreciation a ton-mile	1.09c
Total cost a ton-mile	6.01c

A reduction of 10 per cent. in the price of Goodyear truck tires was announced April 20 to take effect immediately, this being the second cut since Jan. 1.

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

OVERLOADING THE MOTOR VEHICLE.

Most owners of motor wagons believe they are economists when they overload a machine. Many will unhesitatingly carry as much more than the rated capacity as they can. They know the guarantee often depends upon keeping to the weight limit, they know they are subjecting the tires to excessive strains, they know they are incurring excessive wear, but the supposition is that so long as those who guarantee the machine and its tires do not know, they can abuse the vehicle and claim defect in the event of failure. The purchasers know the capacities of the vehicles, and if the requirements are greater than these it would be far better judgment to buy what will be sufficient to meet them rather than permit what cannot be otherwise than destructive and very expensive. Those who own motor vehicles seldom realize that one overload may badly damage a set of tires, or necessitate costly repairs. It may be accepted for all machines that the makers will establish load maximums that are all that can be carried with safety, and to exceed these is to incur certain expense and deterioration that cannot be anything else than costly.

THE TARIFF PROBLEM.

The provision in the Underwood bill now pending in Congress that will cause revision of the tariff if passed, reducing the import tax on automobile chassis from 45 to 30 per cent. ad valorem, and on finished parts of automobiles from 45 to 20 per cent. ad valorem, has aroused the motor vehicle industry to the most vigorous opposition to the measure. In consideration of the bill the importance of foreign automobiles was given hearing, and this privilege was denied to Americans, whom, it would seem in any sense of justice, should be considered first of all.

The automobile industry of the United States does not represent trusts. Every concern is in active competition with the other. The people have a choice as to the quality and type of machine and the wage earners are the beneficiaries, no matter whether or not the manufacturers themselves make profit. The manufacture of motor vehicles for pleasure has developed some large concerns, but in no instance can it be maintained that growth has been due to the taxation of imported vehicles. The industry today represents an enormous investment, and upon it directly and indirectly hundreds of thousands of people are dependent.

To attain its present proportions—for the production of automobile vehicles is one of the very large industries of the nation—to develop the machines to the highly perfected and efficient vehicles they now are in a very brief time as measured by other industrial progress, has cost enormous sums, and the actual prices charged for American automobiles are really small when the value is measured by the cost of conveyances of similar capacity built even five years ago.

The passage of the tariff bill in the form proposed will certainly benefit no one, and its effect will without doubt react upon the industry. It is too great a factor and too important to be crippled, but a change in the tariff would not mean that the people would get better or cheaper automobiles, and it might lead to such conditions that those who are now dependent upon the industry might be materially affected.

MOTOR HAULAGE AND TAXES.

The endeavors of the legislators of several states has been directed toward the taxation of motorized service wagons, generally with a view of increasing the revenue that can be expended on state highways. With these machines already taxed as property and the owners thus contributing toward the maintenance of roads, to impose a further tax is certain to discourage the use of such vehicles. This is not only a result that will necessarily retard the industry to a material extent, but it means that the public will be denied the advantages of the improved transportation. Speed in business transactions is worth more to the purchasers than the sellers, and to deny the people the benefits to be obtained through the use of motor wagons means that they must be taxed for the more expensive and less satisfactory animal haulage. The assumption may be that the owners of trucks would pay the tax, but in the end it would be the public.

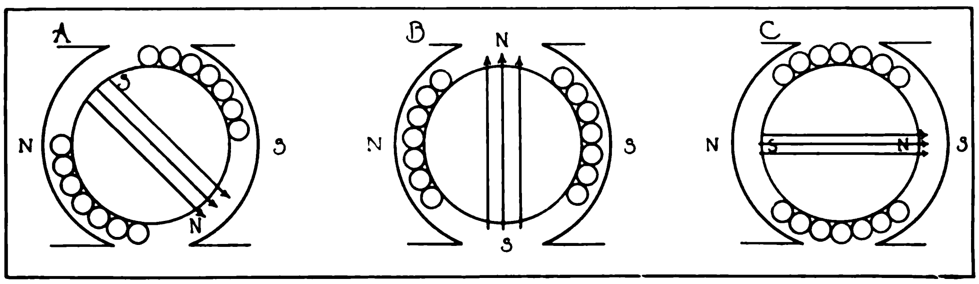
ELECTRIC VEHICLE PRACTISE.

The Transformation of Electric Energy into Mechanical Effort---The Action of the Motor, the Principles of Counter Electromotive Force, Winding Classification, and the Series Wound Construction Used for Vehicles.

By William W. Scott.

IN CONSIDERING the electric motor, it is understood that the pole or field pieces represent north and south poles, between which a magnetic current will flow or is flowing. But the field pieces are not permanent magnets and unless there is residual magnetism, or there is a current of electricity that will excite them, there is practically no flow of energy. When energized the pole pieces create a magnetic field, and it is this field that, acting upon the conductor moving within it, exercises the propulsive effort. The principle is that a conductor carrying an electric current has a tendency to move if placed within a magnetic field.

Were there no conductor there would be an uninterrupted flow of current from the north to the south poles, there being no change in the lines of force. But with the conductor interposed the lines of force passing from the segment forming the north pole to the segment forming the south pole will seek to establish parallelism with the lines of force between the poles of the field magnets. It is practical to describe an electric motor as a construction having a magnetic field, which is produced by field magnets, with conductors in the form of the armature, the armature being so suspended on bearings that it may move when it becomes influenced by the magnetic field.



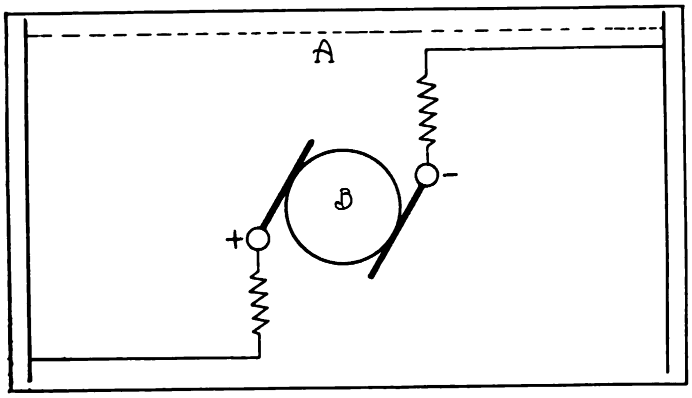
Magnetic Influence in Motor Action: A, Armature at 45 Degree Angle to Lines of Force, Has Greatest Effectiveness; B, Armature Horizontal to Lines of Force Has Least Power; C, Armature Vertical in Lines of Force Has Greatest Resistance.

The creation of a magnetic field within a loop of wire or other conductor, when influenced by an electric current, so that the loop possesses all the qualities of a magnet, is the fundamental principle of dynamos or motors, and it is practical to determine this magnetism with exactness and to anticipate polarity. Each convolution of wire in a winding carrying a given current possesses a definite magneto-motive force, and with the increase of these convolutions the force is increased, the magnetism being forced through the wire. The turns of wire intensify the current, and when they are arranged so that their effect upon each other produces motion the power resultant is proportionate to the magnetic influence caused by the arrangement of the coils and poles, and, of course, the speed of rotation.

When the lines of force of two fields meet and seek to establish parallelism, the arrangement is tangential with reference to the line of one field, and in the case of the electric motor the lines of force pass from the north to the south pole through the armature core. When the armature core is wound with wire it may have a number of positions with reference to the vertical or horizontal plane. To illustrate this it may be well to consider several positions, the first of which may be with the coil in the horizontal plane. This may be noted in the illustration. Assuming that the coil has not influenced the magnetic field, the lines of force pass from the north to the south poles of the magnet, but when the coil is energized by a current it manifests every quality of any electro-magnet despite it being within a magnetic field. The core of the armature is soft iron laminae, and the core is magnetized by the current circulating in the coil. Without the core the magnetic influence of the current would be weak, but with the core it is greatly intensified, and the lines of force of the coil are at right angles with those flowing between the poles. As the poles of the coil will seek the opposite poles of the original magnet, this causes a movement of the coil or armature in the direction governed by the location of the poles created by the ampere-turns of the horizontal coil and those of the field in which the armature core is suspended. As the tendency of the lines of force of the coil is to establish parallelism with the lines of force of the magnetic field motion is created.

But assuming that the coil is in a vertical plane, the magnetic field produced by the coil is at right angles to it, or in a horizontal plane, and these will unite with those of the field of the magnets, but if the poles are opposed the lines of force of the coil will be reduced proportionately to the magneto-motive force. But in this position no motion will be created, as the lines of force will be in parallelism. Between these two extremes another position may be assumed, where the coil and armature is at an angle of 45 degrees with reference to the horizontal and vertical positions assumed, and the magnetic field of the coil is at right

angles to the coil. Here the position of the poles of the coil field is such that movement of the armature must follow, and a strong impulse is manifested, for it



Principle of Counter Electromotive Force: Assumed Difference in Potential Between Terminals 110 Volts; Assumed Counter Electromotive Force 109 Volts; Effective Electromotive Force, One Volt.

is only through moving the coil that the lines of force of the coil can establish parallelism with those of the magnetic field. From this statement it will be noted that slightest variance from the parallel position of the lines of force will impart movement, and it follows that there is a constant tendency of the lines of force of the magnets, which have fixed relation as to influence, and those of the armature coils, to parallel when the latter are in certain position with regard to the magnetic field.

A more simple manner of expression might be to state there are permanent magnets that have generally a uniform influence, and a number of electro-magnets that may be moved, the fields of the latter having a tendency to reach such positions that their lines of force will be parallel with and in the same direction as those of the former. Consequently, as the current is increased, there is attraction of the movable electro-magnets of the armature coils by the permanent magnets of the motor, proportionate to the current. It may be well to instance that the torque of the armature becomes simply a matter of magnetic field and the current in the armature.

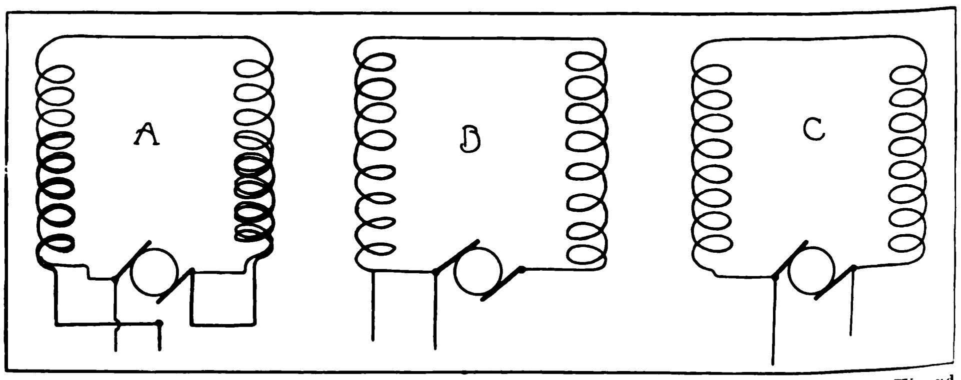
It is possible to very accurately determine the attraction of an electro-magnet and convert it into an expression of mechanical pull or effort, this being a simple equation in which the factors are pull in dynes, line of force a square centimeter, area of the poles in square centimeters, and the circumference, represented by 3.1416.

Reference has been made to counter electromotive force and its influence upon the load upon a motor and the power it will consume. That is, the motor will automatically adjust itself to conditions of use through the counter electromotive force, which moves in the opposite direction to the movement of the armature. This force is created within an armature in precisely the same manner and for the same reason that any other electromotive force is developed by conductors rotating in a magnetic field. Though the motor armature will rotate from the reaction between the field of the magnets and the field of the conductors, the armature has exactly the same influence as free conductors revolving in a field, in that the lines of force are cut and electromotive force is produced. The counter electromotive force may be accurately determined.

In illustrating this the action of a motor armature may be assumed. As current enters the motor the field magnets are energized and this current to a certain degree passes through the armature. The effect of rotating the armature creates an electromotive force within the armature conductors. But there are two electromotive forces active within the armature, one of which sends a current through it, and the other opposes the effect of the entering electromotive force. The electromotive force energizing the motor is known as the line or impressed electromotive force, and the electromotive force generated within the conductors of the armature is known as the counter electromotive force.

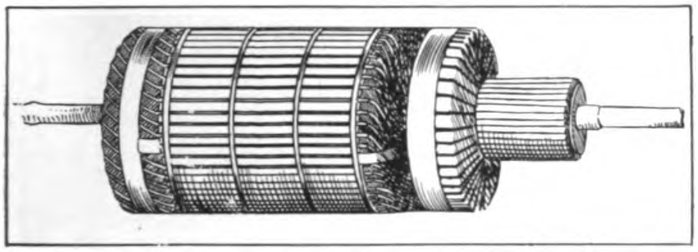
The electromotive force may be varied by conditions with reference to generation, lines of force and conductors, and increase of the number of conductors of a motor armature will create an increased or higher counter electromotive force. If the speed of a motor be changed there will be a corresponding change in the counter electromotive force, while there will be similar change through the variance in the strength of the magnetic field.

The impressed electromotive force is the result of a current sent through the field magnets and causing a field of a definite influence, and through the armature producing a rotative effect and power. A fact that is noteworthy is that when a motor is operated without a load the greatest counter electromotive force is developed, and because of this the current sent through the armature by the impressed electromotive force is at a minimum. The difference between the counter and the impressed electromotive forces is the effective electromotive force. The resistance of the armature governs the current that will be sent through it by the effective electromotive force. This may be illustrated



Examples of Motor Wiring: A, Differential Wound, Constant Potential; B, Shunt Wound, Constant Potential; C, Series Wound, Constant Current.

by assuming that an armature has a resistance of .01 ohm, the impressed electromotive force is 110 volts, and the counter electromotive force is 109.5 volts. The



Series Wound Motor with Resistance in the Circuit, Represented by Rh.

difference between the two is .5 volt, and this would be determined as to current by .5÷.01=50 amperes. This formula may be applied to any resistance and to any voltages, and the result will be the effective current. With low resistance a very small effective pressure will send a heavy current through the armature. In connection with this it should be understood that the changes of the load will vary the motor speed, and it will increase or decrease as the load is increased or decreased. With this variance there is also corresponding change in the counter electromotive force, and the current passing through the armature will vary. The effect of the counter electromotive force is to automatically resist the speed when the motor is driven fast, and its resistance is less when the motor is driven slow.

Motor classification is established by the character of the windings and the form of current by which machines are operated. Motors of the direct current type are differentiated as the constant current series wound, constant potential shunt wound and the constant potential differentially wound. These types are each distinct with reference to windings, but the last mentioned is a combination of the first two. Vehicle motors are generally the series wound machines, which are mainly utilized with direct current circuits or sources of supply whch afford constant current and constant potential. The other types are used for other purposes.

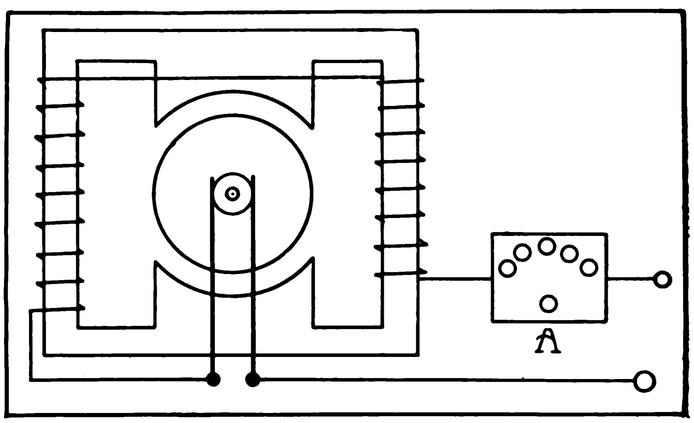
In the design and construction of a motor, speed is a very important factor, and it may be either a constant or variable speed type. It is practical to vary speed, and to control it, by using a resistance in series with a motor, which will govern the voltage and amperage it will receive. But when constant speed is required this may be best obtained by differential winding. The series wound motor will increase in speed as the load is reduced, and will reduce in speed as the load is increased, but the shunt wound motor will maintain a reasonably constant speed when the load is varied. It may be well to define the differentially wound motor as one in which the strength of the magnetic field is variable, so that the strength is the greatest when the load is small, and the field is reduced in strength when the load is heavy.

The series wound motor as developed for motor vehicle service has very long endurance and is regarded as being the most serviceable type. In considering this construction it is well to understand the effect from variable voltage, current and load. The same current is necessary for the field and for the armature, and the machine is very susceptible to the variation of the counter electromotive force of the armature. The current that is passed through the motor may be determined with great accuracy, the current being equal to the difference between the line voltage and the counter electromotive force divided by the resistance through the armature and field in ohms.

It will be understood that as the resistance is increased the current will be lessened, and the current will decrease with the increase of the counter electromotive force. More current will flow as the voltage supplied to the motor is increased, and this will increase the speed of the armature and cause a greater torque or effective movement. The electromotive force is varied by variation of the field strength, and a reduction may be effected by shunting the field winding or short circuiting a part of the lines of force, which lessen the number of lines of force cut by the armature and reduce the counter electromotive force. With the series wound motor no more current can pass in if it is fully loaded and on a constant current circuit, so that there is lessened pull from the diminished field, and speed is reduced.

But a series wound motor must never be operated without load, for the tendency of the machine is to increase its speed to such a velocity that destruction would follow. As applied to the vehicle there is always a load to be carried, and this affords the automatic regulation that follows with work of any character.

The alternating dynamo or motor is built with the windings of the armature connected with the collecting rings, and the direct current machines are constructed with the windings connected with the commutator. In usual practise the armature may be either the drum or ring type, the drum being built on a spindle or sleeve that is carried on a spindle, and the



A Typical Drum Armature and Commutator, Showing the General Characteristics of Construction.

ring being supported by a spider. The drum type is regarded as being a very desirable construction. The drum armature is constructed of a series of circular

plates of soft sheet iron that are insulated by enamel or varnish, the plates being forced into contact to make a solid cylinder. In the peripheries of these plates are notches, and the discs are so placed that when assembled there are channels or grooves extending the length of the armature. The number of channels is carefully determined, for the danger of eddy currents decreases with the increase of the grooves. The production of eddy currents causes heating and perhaps other complications, and it is essential that this danger be minimized so far as possible. The use of the soft iron plates for the core is that there may be a high degree of magnetic permeability, for it is necessary that there be the lowest resistance of the armature to insure the use of minimum current when performing a given work.

Into the grooves in the armature core the windings are laid, with proper insulation, and the power of the motor is dependent upon the character of the windings. The windings are connected with the commutator, and the commutator collects the current produced by the cutting of the magnetic lines of force, so that they may be caused to concur to a desired result. By the commutator an alternating current is transformed to a direct current. Commutators vary in design, but the application is practically the same. A commutator as it is generally built is composed of a series of copper pieces, L shaped, with the longest arm placed longitudinally, or parallel with the armature shaft, and the shorter arm connected with the insulating disc at the end of the armature drum. These segments are separated by insulators that form similar segments, and each piece of copper is a point for connection between two sections of the armature winding. This construction makes possible the collection of the currents induced in the winding at predetermined points. As has been pointed out, while the result from the magnetic induction of the armature windings is the production of an alternating current, there are points at which the induced current will always move in one direction, a condition due to the permanency of the magnetic influence at these points.

These points are defined as the points of commutation, or neutral points, and the points are the locations for the brushes which form the terminals of the outside circuit, that the current sent over that circuit may be perfectly constant. As the armature rotates the brushes bear upon the conducting segment of the commutator at the exact neutral point, which neutral lines are at either extreme of the determined diameter of commutation, and in theory, at least, the diameter is at right angles to the magnetic lines of force, as estimated for a two-pole magnet. The angle, however, is slightly varied by the magnetic lag. As stated, there is excellent reason to have the number of channels carrying the sections of armature winding as numerous as is practical, and the series of segments of the commutator is governed as to number by the character of winding. The greater the number of the collecting members in the commutator the less the fluctuation of the current and the less the possibility of arcing or sparking, but the segments must not be so numerous that brushes of sufficient diameter to carry the current will overlap and burn the armature. The size of the commutator is as important as the number of segments it contains.

(To Be Continued.)

BREWERS ADOPT ELECTRICS.

Five Massachusetts Concerns, Three in Boston, Order General Vehicle Machines.

That five Massachusetts breweries have added electric trucks to their delivery equipments, or have orders placed for machines that will be ready for service within a comparatively short time, is an evidence of the growing utilization of this type of vehicle in New England. One of these concerns is A. J. Houghton & Co., Boston, of the Vienna Brewery, which has just placed a five-ton truck, the second of the kind, in its service. The Massachusetts Breweries Company installed an electric truck a few days ago and will add to this a five-ton truck and a two-ton special delivery wagon, which will be delivered in June and July respectively. The Boylston Brewery, operated by Haffenraffer & Co., has placed in service a five-ton truck equipped with an Edison battery. The Worcester Breweries will take delivery of a two-ton wagon the present month, and the Pittsfield Brewing Association, which has now a one-ton truck in use, has ordered two more. All are General Vehicle machines.

TURNTABLE COMPANY INCORPORATED.

Michigan Concern Secures New Factory and Will Increase Its Scope and Equipment.

The T. C. Beach Auto Turntable Company, St. Johns, Mich., has incorporated with capital stock of $10,000 for the purpose of manufacturing automobile turntables. The incorporators and stockholders are: T. C. Beach, R. S. Clark, W. J. Moss and Robert H. Chapin, all of St. Johns.

The cement factory at the crossing of Lansing street and the Grand Trunk railway has been leased, a provision being included for the purchase of the building later if desired.

The Consumers' Ice Company of Boston, which has established a great artificial ice manufacturing plant at Dorchester, will utilize electric trucks for the haulage of its products, and the first of these will be delivered by the General Vehicle Company, Long Island City, N. Y., in June. The engineers of the company, after considering transportation, decided to use these machines, and the bodies will be from designs by Frank B. Carter. It is a coincidence that the Consumers' Ice Company, Sioux City, Ia., has also just ordered two General Vehicle trucks.

THE PHILADELPHIA THIN PLATE BATTERY.

By James M. Skinner.

THE purpose of the Electric Vehicle Association of America is to promote and stimulate the use of the electric vehicle by educational work. The different sections of the organization endeavor systematically to consider subjects that will be useful to the members in the sale, use and operation of electric machines, and which will especially benefit the owners and operators of such vehicles. Members are invited to present papers on topics of special interest or value, and these are followed by discussions of the different phases that may be developed. As may be assumed, these reviews and analyses of fact are extremely beneficial. The following paper, which will be presented in two parts, was read at a recent meeting of the New York section by James M. Skinner, engineer of the Philadelphia Storage Battery Company, and as it deals with advanced battery cell construction and demonstrates the progression made generally in battery engineering, it has unusual interest, although it is confined to the consideration of the cells made by the company with which Mr. Skinner is associated.

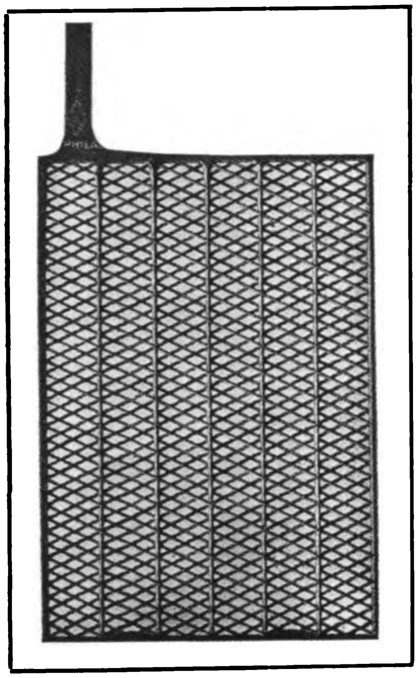


Fig. 1.

The paper is not technical and it can be applied to lead batteries in a general way. The electric storage battery is extremely practical and a great progression has been made in design and efficiency, affording greater mileage capacity and increasing the longevity materially. These facts are established in the following review:

The Philadelphia thin plate battery has now seen six years of service. In spite of the very conservative policy of its manufacturers in exploiting it, it has made good. It is the object of this paper to dig into its characteristics, and to endeavor from a semi-technical standpoint to unearth the reasons for its success. My time is limited. I cannot therefore dwell upon all types of Philadelphia thin plates. Since plates of the W size are manufactured in all of our various thicknesses (W, WM, WT and WTX), I will confine my discussion principally to these, only pausing to state that plates of other areas, such as our CM, CT and R types, are just as much thin plates as our WM, WT and WTX, and embody just the same advantages.

To avoid confusion, in case anyone present does not associate definite thicknesses with the letter names of Philadelphia plates, I may mention that the W plate is .21875 inch thick, the WM .1875, WT .17165, and the WTX .140625. When a new man comes into our laboratory, I try to impress the relative thicknesses upon his mind by telling him that the W is the thick plate; the WM, the medium plate; the M standing for medium; the WT the thin plate, the T meaning thin; and the WTX the extra thin plate, as designated by the TX.

The Diamond Grid.

The WTX is 64 per cent. as thick as the W plate. Possibly your first thought in regard to this statement will be: "Doesn't a 36 per cent. decrease in thickness result in a considerable loss of strength?" I might agree with you that the W plate is stronger than the WTX plate, but I would immediately add that the WTX plate is strong enough, that it, too, contains a large factor of safety. The question of strength was the sticking point which for so many years prevented the employment of thin plates in storage batteries. Until the advent of the diamond grid, no means had been found of securing sufficient strength to make thin plates safe. They would buckle. It was very hard to rid people's minds of that buckling bugbear. Because other thin plates, built on different lines, had been tried, and had buckled, it had become almost a storage battery axiom that buckling was an inherent, incurable thin plate disease. It took several years of non-buckling diamond grids to convince battery users that thin plates did not have to buckle, and even today the same Rip Van Winkle objection is occasionally raised. But such cases are rare. Philadelphia diamond grid thin plates have never been in the habit of buckling, and most battery users have, by personal experience, satisfied themselves that this is the case.

Fig. 1 shows the diamond grid. You can readily understand its strength by considering its construction. Due to the net work of diamond crosses, each part of the plate helps to support every other part. Take the member starting at the lower corner. It runs diagonally across to the other side, then back, and finally across again to the opposite corner. Every other member follows a similar path. A strain on one part of the plate is resisted, not only by the members in the particular region affected, but by the members all through the whole plate. The same idea is used in the arrangement of the members of a bridge truss. It works there and it works in Philadelphia thin plates.

If the diamond grid possessed no other advantage than its great buckling resisting ability, it would still be well worth using. But it does embody other advantages. Notice the arrangement of the members in a double staggered lattice work, with a space between. Notice also that the face of each diamond is backed by a cross, formed by the members of four diamonds on the opposite side of the plate. Every particle of active material is close to a conductor. This is very important. Material far distant from a conductor can never deliver its full quota of energy. Notice further that on each diamond there are four places where members on one face of the plate cross members on the other face. The ability of the diamond grid to lock the active material firmly in place depends on these

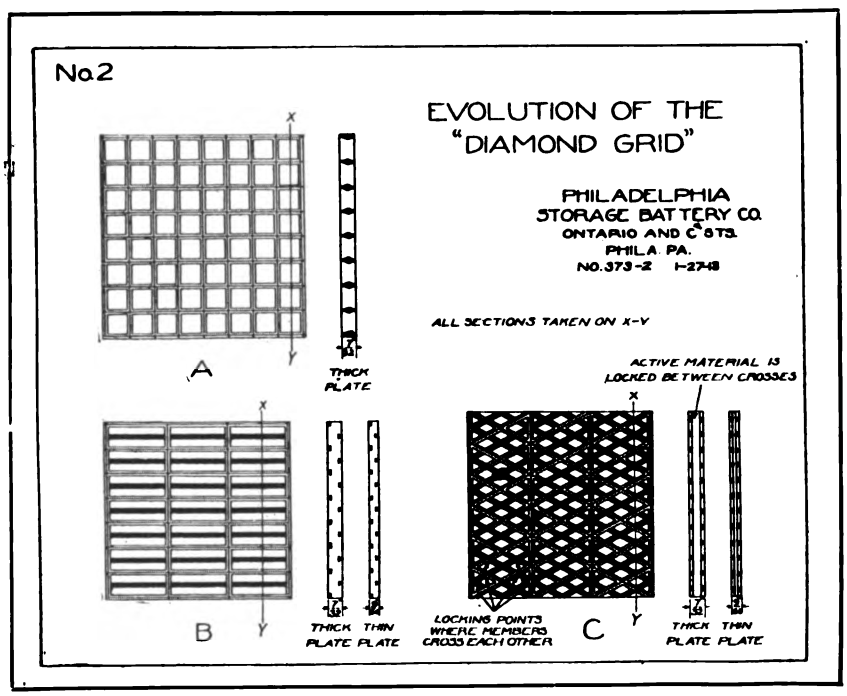

Fig. 2.

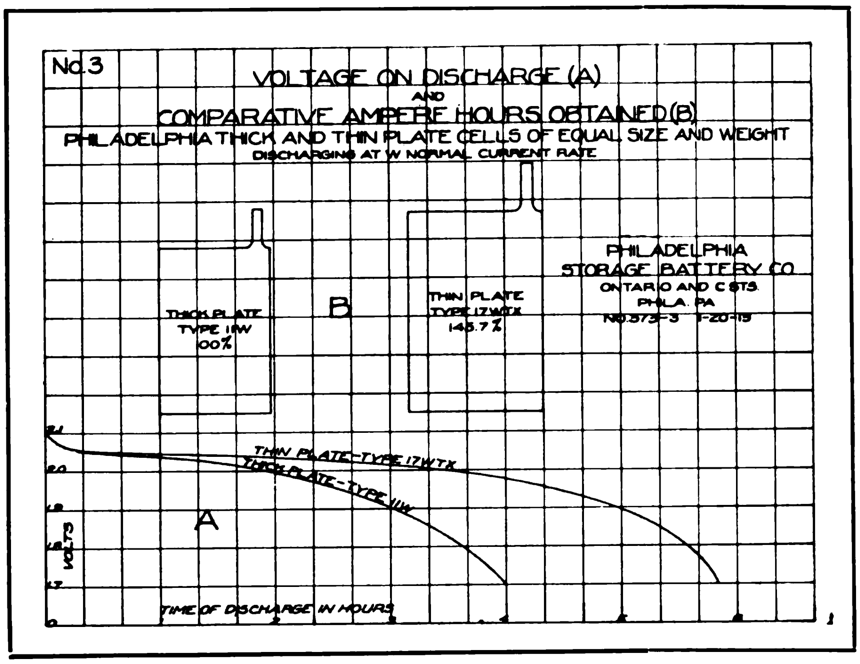

Fig. 3.

crosses. When the material expands, it only presses more tightly upon the grid members. Service jolting cannot dislodge it. It is locked in place. Members that cross each other are an exclusive feature of diamond grids.

Consider for a moment the evolution of the storage battery grid. This is shown in Fig. 2. A shows an early form, merely a single lattice work. Here the material is not locked at all. It is packed in in isolated blocks, which can easily come loose and fall out. B shows a double lattice work grid which, for thick plates, is a distinct improvement on the single lattice. The material is continuous, and offers more or less mutual support. On a thick plate there is some locking, due to the wide space between the lattices, but notice that when the plate is thinned down, it approaches nearer and nearer to the form of the obsolete grid shown in A, and the locking characteristic is practically lost. C shows the diamond grid. Notice the four locking points on each diamond. Notice further that when the plate is thinned down the same locking quality is maintained. The material is bound between the lattices in a thin plate just as firmly as between the lattices in a thick plate. It is interesting to consider buckling resistance here. Notice the diamond grid members are continuous down the plate, not separate as in A and B, and that to bend the plate the resistance of not only the verticals but of the diamond members must be overcome. This figure shows pretty conclusively that the three desirable features for a good thin plate grid, namely, strength, locking ability and conductivity, are all present in the Philadelphia diamond grid.

General Construction.

The Philadelphia thin plate battery is mechanically and chemically correct. Every element entering into its construction is subjected to thorough tests before use. Every process of manufacture is chemically supervised. Plates from every run are tested before the body of the run is O. K.ed for shipment. Extensive laboratories are maintained for these purposes.

In several features the assembling of Philadelphia batteries is unique. The wood separators extend .375 inch above the plates. There can be no short circuits due to bridges over the tops of the separators. The rubber separators are as high as the wood separators, and cannot float up and expose the bottoms of the plates. The wood separators are cut so as to insure mechanical strength. The webs are as thick as the ribs, the spaces between the ribs are only slightly wider than the ribs themselves. Wide solid margins are left unribbed, to give additional strength, to allow for trimming, and to eliminate any chance of short circuits around the edges of the separators. Philadelphia separators do not crush nor split. The initial treatment of the separators is carefully regulated so as to completely remove the impurities without any material reduction in the wood strength. Except in cases of severe ill treatment, happily rare, Philadelphia wood separators usually last the whole life of the battery without renewal.

The batteries are generally assembled in high rib jars with sufficient space beneath the plates to hold all the sediment deposited during the entire life, and cleaning is not required.

Active Material.

The active material in Philadelphia thin plates is of special Philadelphia composition, developed especially for thin plate batteries. This has always been famous for its lasting qualities, and stands with the diamond grid as a large factor in the long life of Philadelphia thin plates. It embodies high coherence and high porosity. The positive material is very slow to soften, and the negative material will not shrink and lose contact with the grid. Philadelphia thin plates maintain high capacity during their entire life.

Mileage and Speed.

The increased mileage of electric cars, due to the substitution of WTX for W batteries of the same weight and size, amounts to about 46 per cent. WT batteries will give 35 per cent. more mileage than W batteries, and WM 20 per cent. more. Fig. 3 shows a discharge, at the same current rate, of W and WTX cells assembled in the same sized jars. The average voltage of the W cell is 1.965 volts, of the WTX, 1.98 volts. Notice how the voltage of the WTX hangs up until almost the end of the discharge. This means sustained car speed.

In service the average voltage of thin plate batteries is often well over two volts, because the full capacity is not usually required every day, and most discharges are not carried down to 1.70 volts a cell. If a WTX battery is only required to give the same number of ampere-hours that a W battery can give, it will finish discharge at about 1.97 volts a cell. The average voltage will then be 2.02 volts.

The speed on any electric car will decrease as the battery discharges, and the voltage across the motor decreases. With lead batteries the percentage variation from the beginning to the end of discharge amounts to about 17 per cent., when the battery is carried down to 1.70 volts a cell. As previously pointed out, the thin plate voltage remains high until almost the end of the discharge. Hence the average speed is only four per cent. below the maximum, even on full discharges. With thin plate batteries discharging to thick plate capacity, the final speed is 96 per cent. and the average speed is 98.4 per cent. of the maximum.

WTX cells contain about 54.5 per cent. more plates than W cells of equal size. This checks rather closely the 46 per cent. capacity increase, and suggests a relation between capacity and the number of plates in a cell. Chemical analysis throws some light on the reason for this. Fig. 4 shows the distribution of discharged active material, that is, lead sulphate, in Philadelphia thick and thin plates, taken from cells discharged to 1.70 volts. These plates were analyzed layer by layer, working in from each side until the centre was reached. The heavier the shading the larger the amount of lead sulphate found. You will note that the discharge is thorough only to a depth of about .03125 inch. The layers deeper than .03125 inch show a rapid decrease in discharged material, until, at the middle of the plate, almost no discharge has taken place. Since it performs so little work it would seem to be good policy to reduce this central core to a minimum. In thin plates it is reduced to a minimum.

It is not the fact that thin plate batteries have greater capacity a plate than thick plate batteries. The capacity a plate is somewhat less, but due to the larger number of plates which can be used, the capacity obtainable from a given sized jar is much greater. A W positive plate will give 28 ampere-hours at the four-hour rate, a WTX positive will give 25.5 ampere-hours at the same current rate. The WTX capacity is 91 per cent. as great, and with only 64 per cent. of the thick-

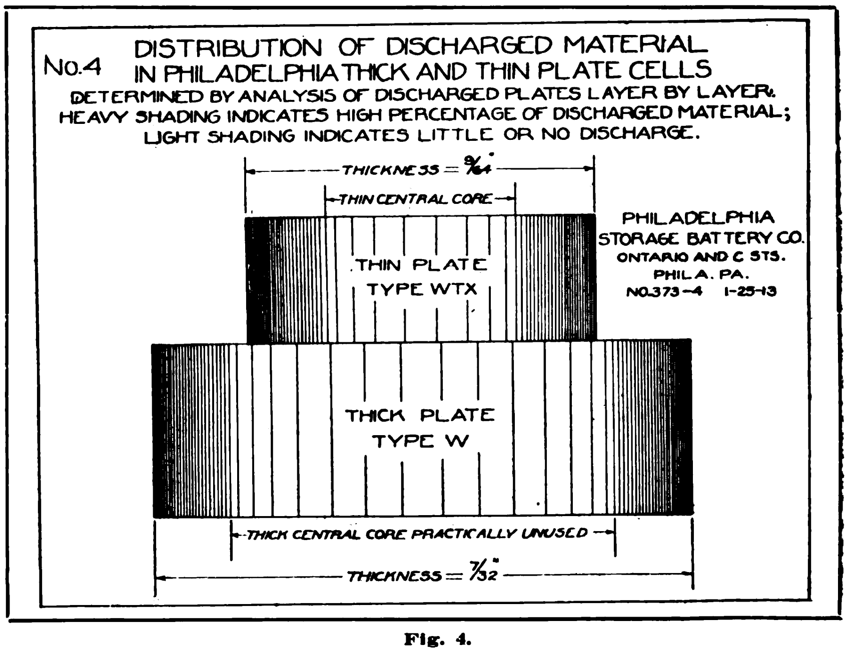

Fig. 4.

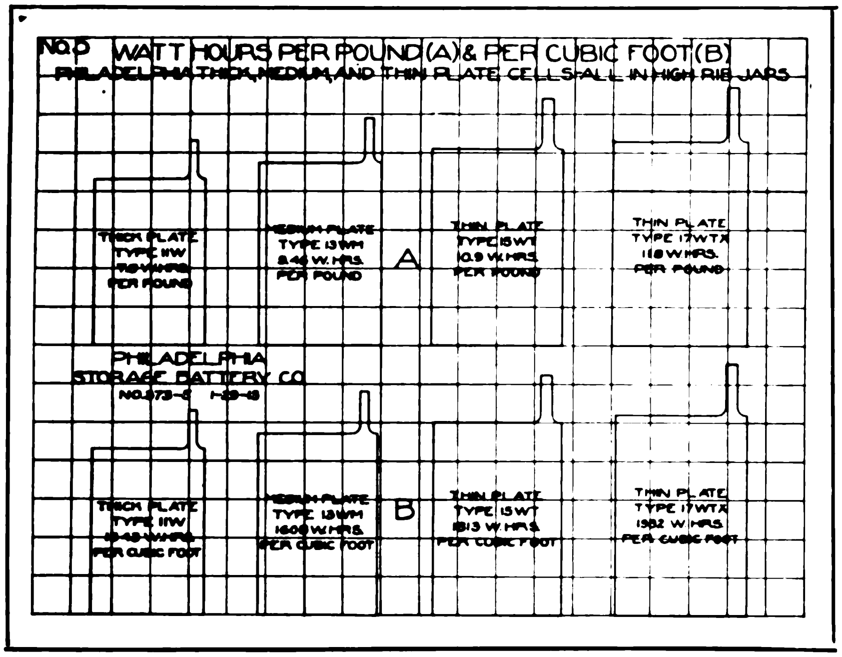

Fig. 5.

ness. In a given jar there can be installed 60 per cent. more WTX positive plates. The relative capacity obtained by substituting thin plates for thick is 160 per cent. multiplied by 91 per cent., or about 146 per cent., as against the thick plate 100 per cent., a 46 per cent. increase, as previously stated.

It has sometimes been assumed that the large central cores in thick plates would result in a better maintenance of capacity when the surface had worn away, and therefore in an increased life. This is not the case. In the first place, as the surface layer of thick plates wears away, they become thin plates. They are not as good as real thin plates, because the material is further away from conductors and cannot as easily deliver its capacity. But assume that the worn thick plates do give as great capacity a plate as thin plates. The battery is then equivalent to a thin plate battery of an equal number of plates, and the capacity is only 91 per cent. of the original thick plate capacity. Moreover the core material is not protected by the rubber separators, and it sloughs off much faster than the surface material. The life after the surface of the plates has worn away is therefore short, and the capacity is below rating. The full capacity of thick plate batteries is not great, and when it falls below rating, the mileage obtainable is usually less than the service demands, and the battery must be scrapped. Even if the low mileage can be utilized for short trips, it can be maintained for only a comparatively few discharges.

On thin plate batteries the material does not wear away as fast as on thick plate batteries. In the first place, the discharges are not carried to such a low voltage, and the material is less loosened up by oversulphation. In the second place, there is less gassing on charge, due to the greater accessibility of the discharged material to the charging current. Gassing is the most damaging factor in shortening battery life. In the third place, there are more plates over which this smaller amount of gas is distributed, and the wear a square inch a charge is less than half as great. In the fourth place, the material in diamond grid thin plates is if anything more firmly locked in position than in diamond grid thick plates. Moreover a great deal of material must be lost before the plates fall below their rated capacity. Philadelphia thin plate batteries maintain full rated capacity until almost the end of their lives.

Weight and Space.

The increased capacity of Philadelphia thin plate batteries is obtained without any increase in weight over thick plate batteries. In fact, a WTX battery is three per cent. lighter than a W battery assembled in WTX high rib jars. The W battery is, however, usually assembled in low rib jars, a distinct disadvantage, because cleaning is required. The WTX battery in its high rib jars weighs just about the same as the W in its low rib jars.

A WTX battery gives about 11.8 watt-hours a pound of cell. It does not seem, however, that this is a matter of any extreme importance. Consider a car, the weight of which without the battery is 8000 pounds. One battery for this car may weigh 2000 pounds, the other 10 per cent. more, or 2200 pounds. With battery No. 1 the car will weigh 10,000 pounds, with battery No. 2, 10,200 pounds. For a 10 per cent. increase in battery weight, there is only a two per cent. increase in car weight. Suppose battery No. 2 costs less, is a better hill climber and gives better speed and quicker starts, has higher efficiency, and gives greater mileage. The two per cent. increase in weight looks very, very small.

Philadelphia WTX batteries will give 1932 watt-hours a cubic foot of cell. This is the highest at present obtainable. Since the battery compartment space on standard cars is limited, the high capacity a unit of volume is a big point in favor of thin plates.

Fig. 5 shows the watt-hours a pound of cell and a cubic foot of cell obtained from various Philadelphia types. Note the steady increase from W to WTX.

Hill Climbing and Acceleration.

A beautiful feature of Philadelphia thin plate batteries is their ability to maintain the speed of the car on hills or on bad roads, and to get the car up to speed quickly on starts. The fundamental reason for this is the extremely large active surface that they present. The number of plates is the biggest factor here, but the diamond grid plays its part by obstructing less of the surface than usual with inactive grid.

Fig. 6 shows the relative plate surface of W and WTX cells in the same sized jars. The WTX shows a 54.5 per cent. increase. This surface is not enclosed by any material obstructing the passage of the acid and current to it. It is all cleared for action. When a battery is called upon to supply a high rate of current, the acid in the electrolyte in immediate contact with the active material is quickly exhausted. If the voltage of the battery and the speed of the car are to be maintained, it is essential that fresh acid from the body of the cell should diffuse to the active material quickly, and this is just what the large surface of Philadelphia thin plate batteries insures.

Thanks to the large plate surface and to the splendid conductivity of sulphuric acid, the internal resistance of Philadelphia thin plate batteries is very low. This is essential for good hill climbing ability. If the internal resistance of a battery is high, it cannot deliver heavy currents without a great fall in voltage, and a corresponding reduction in car speed. A high resistance battery can, of course, be short circuited with less danger, because of the great drop in voltage and the relatively small current that therefore flows. But this is of minor importance. Short circuiting is never required in service, and we can recall no instance of a Philadelphia thin plate battery having been accidentally short circuited to a sufficient extent to cause any damage.

The variation of internal resistance during discharge, in 11 W and 17 WTX cells, is shown in Fig. 7. Notice that the thin plate resistance is considerably less than that of the thick plate, and notice that it keeps low during almost the entire discharge, just as the voltage kept high.

Another result of large plate surface is high average voltage. Fig. 8 shows the average voltage of W and WTX cells, during discharges at various current rates up to six times normal. Notice how the WTX holds up at high rates. It is of the bull dog, stick-to-it nature that won't let go. It is easy to see why Philadelphia thin plate batteries are such good hill climbers, and are so well adapted to the many starts and stops of electric vehicle service.

On this chart have been plotted also curves showing the ampere-hour capacity at various rates of discharge. The ampere-hour capacity here decreases with increasing discharge current. But this is true only of continuous discharges. In

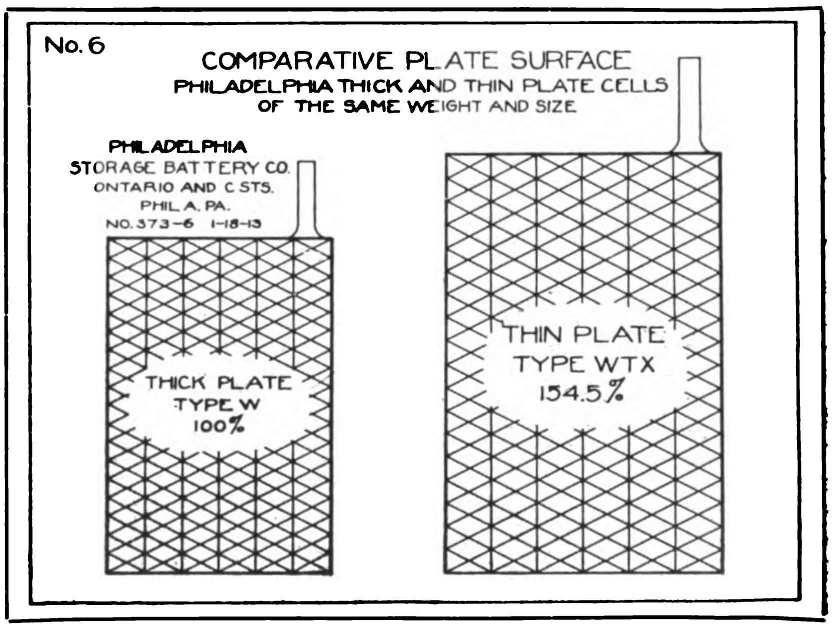

Fig. 6.

service all discharges are intermittent. The factor determining whether more or less than rated ampere-hour capacity will be obtained from a lead battery is the amount of time allowed for fresh acid to diffuse into the plates. A continuous discharge at the three-hour rate allows only three hours for acid diffusion, therefore, fewer than normal ampere-hours are obtained. On the contrary, a discharge at the three-hour current rate, but spread over six hours, allows just as much time for diffusion as a discharge at the six-hour rate, and will give more ampere-hours than the curve shows. In service, discharges often extend over periods of a day or more, and the

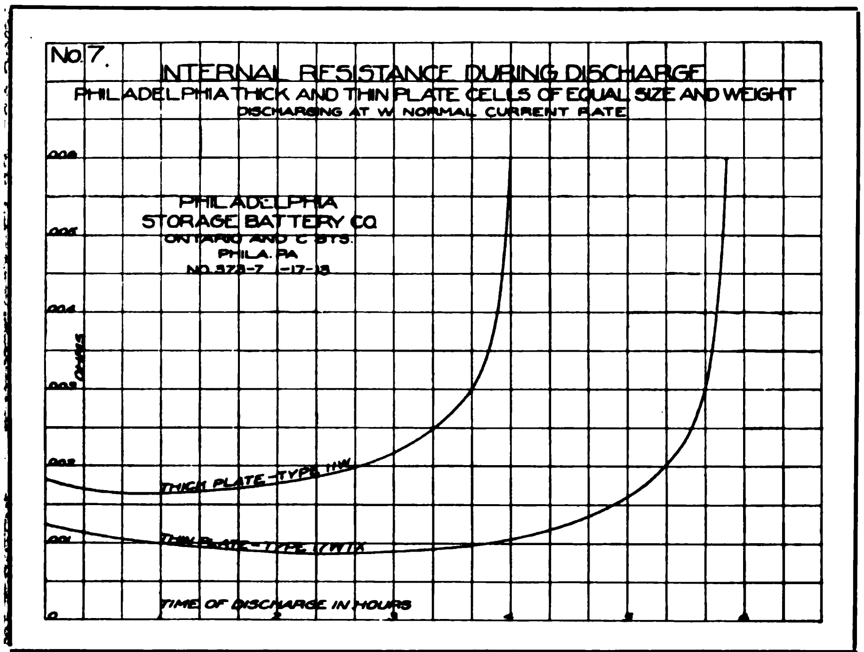

Fig. 7.

ampere-hour capacity of lead batteries may then be considerably over rating. Most electric car service does not call for normal rates of current. Either the car is drawing a high rate, or it is coasting. Thin plate batteries, with their high average voltage and low resistance, are particularly well fitted to meet these conditions.

High average voltage and low internal resistance are advantageous also from the standpoint of ampere-hour consumption. When a given car meets a given grade or a bad stretch of road, a definite tractive effort must be exerted to overcome the resistance. The tractive effort depends upon the torque of the motor. The torque of the motor depends only upon the current supplied to it by the battery, not upon the voltage. To move the car at all, against a given resistance, the motor requires a definite current regardless of the types or size or voltage of the battery which supplies it. But the higher the voltage at which this required current is delivered, the faster the motor will run, and the greater the car speed will be. If the battery voltage is high, the car speed will be high, the car will consume less time a mile, and the number of ampere-hours used a mile will be low. If the battery voltage is low, the speed will be low, the time a mile, and therefore the ampere-hour consumption a mile, will be high. To take a concrete instance, consider two cars, identical as far as make and load are concerned, and containing batteries of equal voltage at normal current draw. Suppose that one battery is of high internal resistance, and that its voltage therefore drops off considerably at high current draws, and that the other battery is of low internal resistance, and that its voltage therefore remains high at high current draws. Assume that a hill one mile long must be climbed, and that the current demanded by the motors, in order that they may exert enough torque to move the cars at all, is 100 amperes. The car with the high resistance battery may run at five miles an hour, or one-fifth of an hour a mile. The low resistance battery may give seven miles an hour, or one-seventh of an hour a mile, due to its higher voltage. The high resistance battery must deliver, on the one mile grade, 100 (amperes) x one-fifth (hours) = 20 ampere-hours; the low resistance battery 100 (amperes) x one-seventh (hours) = 14.3 ampere-hours, a saving of over 25 per cent. in ampere-hour consumption to do the same work, to say nothing of the saving in time. The ground that an ampere-hour of capacity will enable a car to cover varies widely with the type and voltage characteristics of the battery that supplies that ampere-hour.

RECENT PATENTS.

Gear Shift Lever Device, Phares W. Brubaker, West Reading, Penn., No. 1,057,524. A lever working within a slot, one side of said slot being provided with a flexible portion, means for converting said flexible portion into a rigid portion, and means whereby said flexible portion controls the movement of said lever.

Valve Gear, Daniel Appel, East Cleveland, O., No. 1,057,399. In combination with the crankshaft and cylinder of an internal combustion engine, a valve adapted to control, both the inlet and exhaust of gases from the cylinder, a valve rod connected to the valve, and a valve gear comprising a member which has a connection with the valve rod, and means for operating said member so as to impart to the axis of said connection a hypocycloidal path of movement.

Sleeve Type Two-Cycle Engine, Clarence D. Miller, Philadelphia, assignor of one-third to Harry F. Haviland and a like amount to Warren J. Miller of the same city, No. 1,057,442. In an internal combustion engine, a cylinder having in its walls an exhaust port, a sleeve within said cylinder, said sleeve provided with a pair of ports located in different horizontal planes whereby upon the reciprocation of the sleeve in the direction of its axis, the sleeve ports will register successively with the cylinder port, to provide initial and final discharge of the exhaust gases.

Vehicle Wheel, Thomas B. Jeffery, Kenosha, Wis., and Kate E., Charles T. and Harold W. Jeffery, executors, No. 1,056,278. In a vehicle wheel, the combination with the spokes thereof, a two-part spoke head secured to the end of each spoke, flanges on the upper ends of the two parts of each spoke head forming a dovetail channel between the same, a tire rim removably surrounding the spoke heads, dovetail lugs on the inner surface of the tire rim engaging the dovetail channel in the spoke heads and means for forcing the flanges on each spoke head toward each other and against the interposed lug.

Cushion Tired Wheel, Norman Gratz, Boise, Idaho, No. 1,056,167. A wheel tire, comprising an inner rim having radial side flanges, an outer rim composed of segmental sections having inwardly extending side flanges formed with radial slots, means for pressing the outer rim sections outward yieldingly, channelled cross bars secured to the side flanges of the inner rim and extending through the slots in side flanges of the outer rim, rollers carried by the cross bars and arranged in said slots, and with which said channels communicate, a lubricant receptacle and connections between the receptacle and the channel of the cross bars.

Life Saving Apparatus, Clayton E. Frederickson, San Francisco, Cal., and Ivy Baldwin, Alameda, Cal., No. 1,056,271. A portable body catching apparatus, mounted on a motor vehicle, comprising a bed frame, arms rockably mounted at each side of the frame, a crankshaft, devices connecting said shaft to said arms at each side of their fulcrums for swinging said arms inwardly and outwardly in a plane at right angles to the frame, and a flexible body connected to the side arms and adapted to form a net or apron for receiving a falling body thereon.

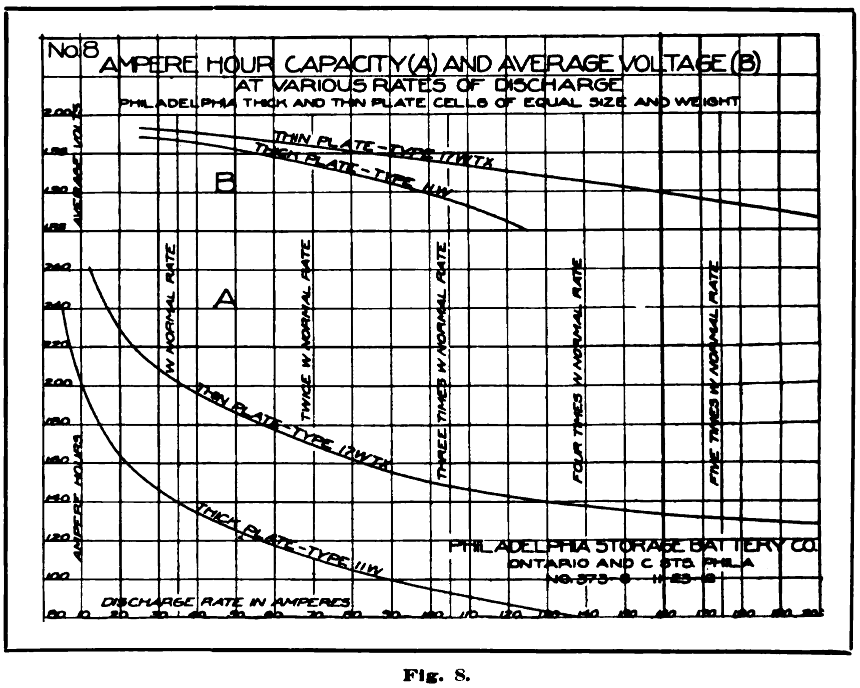

Fig. 8.

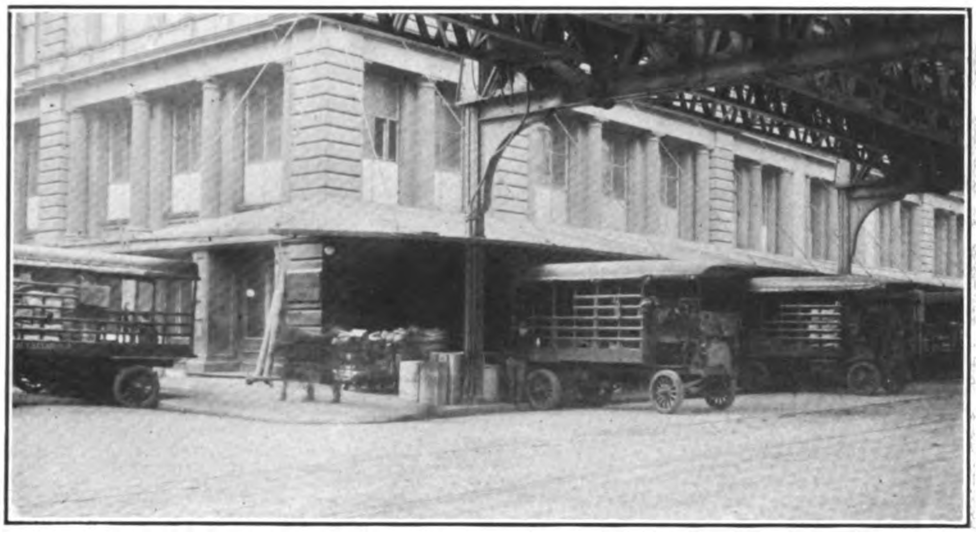
WHOLESALE DELIVERY IN NEW YORK.

Metropolitan Distribution of H. B. Claflin & Co., Largest Concern of the Kind in the World, by Motor and Horse Vehicle, the City Being Divided into Districts, Each of Which Is Systematically Served.

DOING a business of approximately $40,000,000 a year and regarded as the largest concern in America, if not in the world, engaged in the distribution of dry goods at wholesale, the house of H. B. Claflin & Co., at Worth street and West Broadway, New York City, maintains a delivery service that is in every way out of the ordinary. This house is known the world over as a wholesaler, but it has the control of 38 large retail houses, which are of the type known as department stores, located in about 34 different cities outside of New York. These stores are supplied to a considerable extent through the New York house, but much of the export trade is supplied by shipments made from Boston, while in many instances goods are sent from the mills, shops and factories direct to the stores. No statement can be made as to the value of the business transacted with retail establishments in New York and its suburbs, but it is very large and can only be measured by millions annually.

The fact that a considerable part of the business transacted is not handled from the New York store is emphasized because of the possible assumption that the delivery system with which this article has to do is sufficient to handle the entire volume of trade represented by the amount stated. In New York the retail stores are Lord & Taylor, James McCreery and O'Neill-Adams. Besides supplying these the company distributes stock to hundreds of stores throughout Greater New York and its suburbs, these being regular and occasional customers.



Loading H. B. Claflin & Co's Trucks at the Shipping Room at Worth Street and West Broadway, the Elevated Tracks Being in the Latter Thoroughfare.

The goods stocked at the store or combined office and warehouse at Worth street and West Broadway, and at the warehouses in Leonard and Hudson streets are received in shipments from all parts of the country and from abroad, and from the city and its suburbs. This means that practically every railroad terminal and nearly all of the docks must be reached by the transportation department, and in some instances the local factories, although most of the New York manufacturers deliver the goods they sell to the company. Besides this the shipments are so widely distributed that it is necessary to send them through at least a majority of the transportation companies.

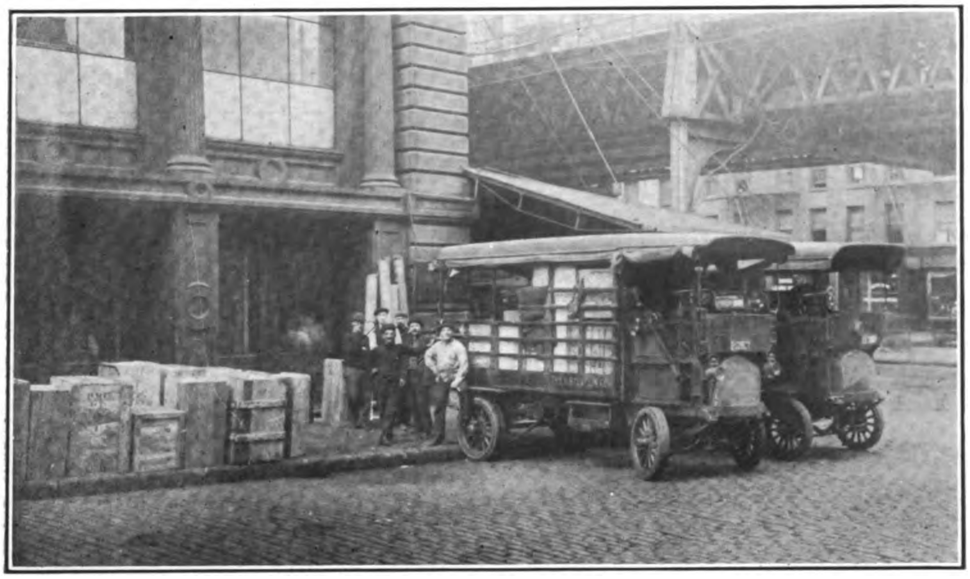
No other business house in New York is required to make use of so many different means of transporting its receipts and shipments, and it is very improbable that there is another that equals it in the number of its city and suburban deliveries. The goods received by the firm are hauled to the main store or the warehouses, oftentimes in large quantities, and stored either in the case or package. More than 100,000 packages are taken from the piers and railroad terminals each year, and these are usually of large size and weight, because the shippers can economize by sending them in the largest single units that can be handled. In addition to these, many thousands of packages are received from local manufacturers during the year.

The main building, which contains the office and a considerable part of the storage space, is a structure of large proportions. The number of people employed in this store is 1800, and while there are many salesmen, the greatest number of employees is engaged in handling the stock. The shipping department is the lower or street floor at the West Broadway end of the building, and in this division are about 200 men and boys who pack and make ready for sending out the cases and packages to be shipped or delivered to customers. At times this number is increased. Besides the force engaged in this work there are others at the different warehouses. It is not possible to average the number of packages sent out daily, because there is so great a variance in demand, but it will be understood that the total is large.

In the section of the city where the store and warehouses are located the traffic is greatly congested from early morning until evening. At the docks and railroad terminals the congestion is probably the greatest

to be found in the metropolis, and this is especially noticeable from 8 in the morning until 6 in the evening. But the street traffic, always dense during the hours stated, is generally dissipated after the close of the working period of the day. Thus during the time when haulage can be done there is probably the largest degree of obstruction to vehicular progress to be observed in America. This fact must be remembered because it has a decided bearing on the expense of distribution, and the progress of transportation is not only retarded by the traffic, but by the regulations that provide for the protection of the people as well as for the use of the streets crossing the main thoroughfares leading north and south.

The shipping department of the company is under the direction of Supt. Hillman, who has been connected with the firm in this capacity for about 30 years, and his knowledge of New York and its highway traffic conditions is probably as broad as any man's in the commercial centre of the nation. For years he did all his work with horses and today utilizes 18 motor vehicles, 12 3.5-ton Vehicle Equipment and General Vehicle electric trucks, one one-ton General Vehicle wagon, and five Mack three-ton gasoline trucks, as well as a considerable number of horse wagons and trucks, these being either two or three-horse teams.



A Corner of the Shipping Room Platform, Showing Two of the Gasoline Trucks Loaded and Ready to Start on the Longer Routes, from Worth Street—All Loading Is Done from the Sidewalk.

In distributing the stock from the store and warehouses it must be remembered that as far north as One Hundred and Twenty-fifth street the traffic during the day is heavy in Manhattan, and as the delivery includes Brooklyn and Jersey City, with more or less congestion of traffic, it will be understood that the speed of the motor vehicle must be governed by the use of the highways. New York street traffic is well regulated and besides the great number of vehicles, in the movement of which the slow retard the fast to a material extent, the swarms of people who must be protected necessitate a much larger part of the delay than is really realized or understood.

Here it might be well to emphasize that for years there has been a gradual increase in cost of metropolitan street transportation despite the endeavors made to improve the conditions through regulation and control, because of the enormous demands for roadway space during the working hours of the day. Not only this, but within the past decade this greater expense has been increased with rapidity that is surprising. This condition will be the better realized when Mr. Hillman's opinion, that for haulage to all parts of Manhattan south of Fifty-ninth street horses are more economical than motor trucks, is stated. This judgment is with a knowledge of the work that can be accomplished with machines and animals, because Mr. Hillman has both in service and has observed them carefully for a period covering about eight years, during which time the motor trucks have been gradually increased. It is necessary, however, to state that this statement is with reference to his own delivery, with units comparatively large, in the heaviest traffic of the continent, and where the conditions for unloading are such as to frequently necessitate delays of considerable length. It is not intended to apply to other deliveries.

In connection with this it is assumed the drivers work as expeditiously as they can and are willing to economize time whenever possible. But all packages must be receipted for, which means that certain men must be found when the deliveries are made, and in some instances collections necessitate loss of time that might be avoided with other service. The loading is accomplished with expedition, but in this work there is no advantage with the motor truck, for the men will require the same time to load any type of vehicle. The freight of a three or 3.5-ton motor truck is about the same as that of a two-horse team and truck, and so far as the Claflin service is concerned the superiority of the power vehicle is its greater speed when the traffic will permit it to be driven faster. When the increased expense of operating the truck is considered Mr. Hillman's statement will be clear and issue will not be taken with it. But the delivery is not the only work that must be done by the transportation department. Practically everything received from the railroads and vessels must be hauled, and a large part of the receipts are from the terminals and docks, where the traffic is the heaviest. A large part of the shipments made is sent to the piers and railroads, but practically all of the railroad companies maintain receiving stations within comparatively short distances of the store and warehouses. In some instances these stations are at

adjacent wharves, where the freight cars are brought on floats and loaded, and in others the shipments are received and transferred by the railroad companies. As all of the railroads have their freight yards outside of the island of Manhattan, and the majority of yards are at Jersey City and Hoboken, these water front receiving stations are a convenience and a great economy to the shippers so far as transportation is concerned.

The weight of the packages for domestic shipment varies widely, but the weights of those made up for export range from 400 to 3000 pounds, and these are sent by automobile truck to the Bush Terminal at Brooklyn or to the Atlas line. The shipments from the Bush Terminal are for South American, Asiatic, California and Hawaiian ports, the last two being via the Tehuantepec railroad from Port of Mexico to Salina Crux. Aside from the export packages practically all of the shipments are delivered to the receiving stations by animal trucks.

In the shipping departments of the store and warehouses the goods are received and packed, and the packages intended for city delivery are prepared with reference to minimized handling. As the orders are made up, sometimes in one case or in several packages, they are verified and checked. Each order is then assigned to a certain route, and the routes as made up include any store within the areas defined as follows:

Downtown route, all of the island of Manhattan south from Worth and Oliver streets to the Battery.

Middle route, from Worth street north to Canal street, and from Center street west to the North river.

Broadway route, that section west of Center street, from Canal to Bleeker streets, bounded on the west by West Broadway.

Lower Sixth avenue route, that section north from Bleeker street to Ninth street, and from Lafayette to West Broadway.

Upper route, that section north of Ninth street to Twenty-third street, and between Fourth and Sixth avenues.

Eighth avenue route, that section north of Canal street to Sixty-second street, west of West Broadway and Sixth avenue.

West Harlem route, the north end of Manhattan from Sixty-second street, west of Eighth and Lenox avenues.

East Harlem route, all that section of Manhattan east of Fifth avenue between Twenty-third street and the Harlem river.

Bronx route, all of the borough of the Bronx.

South Brooklyn route, that section of Brooklyn west of Gold street to Fort Hamilton.

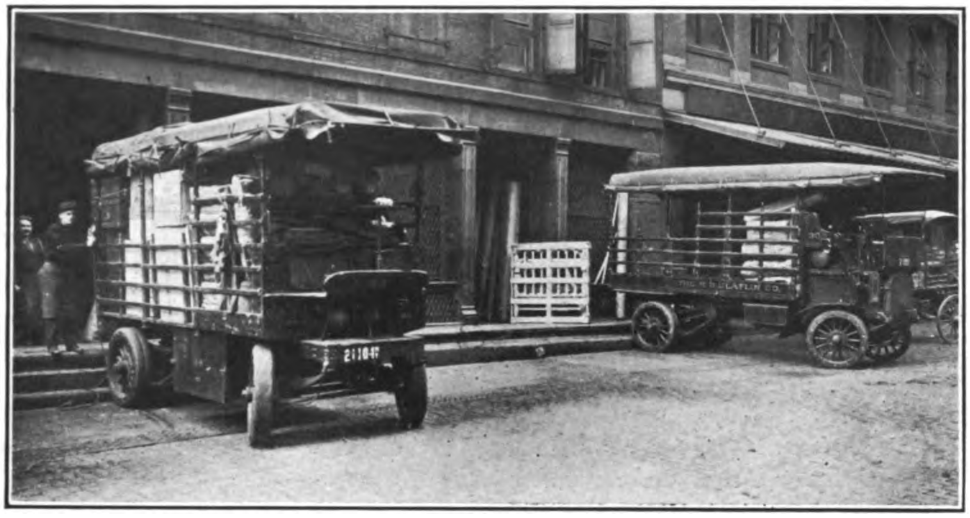
Fulton street route, all that section east of Gold street extending to East New York.

Williamsburg route, that section from the Williamsburg bridge south from Broad street and east of Bedford avenue, out to Ridgewood, east of Graham avenue.

Greenpoint route, that section north of Broadway and west of Graham avenue, out to Newton creek.

In addition to these, deliveries are made at Canarsie, Coney Island, Sheepshead Bay, Jamaica, Richmond Hill, Elmhurst, Astoria and College Point, as well as Staten Island, within the city, and to Jersey City, Hoboken, Newark and even to Hackensack, in New Jersey. The routes, however, are made up to include the customers who must be visited regularly. In some instances the calls are made daily, and with large purchases, several times each day.

The shipping room is a very large department, in which is an office where a clerical force keeps the records of the orders and the deliveries. As the orders are sent to the shipping room office warehouse orders also cause the selection of the stock and when it reaches the shipping force the packages are made up. Each order is first laid out and checked, and when it is packed it is again checked and is placed with the other orders that are to be taken out by a given route vehicle. This route load is accumulated in this manner for each of the routes. It is not possible to determine with accuracy the time when loads will be sent out save in the morning, for the freight of each vehicle will depend upon the size of the orders. In some instances but a few will be carried, and in others a considerable number.



Loading Platform at One of the Leonard Street Warehouses, This Being the Sidewalk at the Front of the Building—These Machines are Loaded for a Regular Morning Route Trip.

The shipping room of the main store frontage is the entire West Broadway end of the building, and it has a series of wide doors for the convenient loading and unloading of the vehicles. Over the sidewalk is a canopy that extends to the curb. The sidewalk is used in one sense as a loading platform, and because

of the requirements of the pedestrians, and that all packages must be lifted, this condition is not as economical as were the shipping from a floor the height of the vehicle bodies and not required for public use. In West Broadway is an elevated railroad and the traffic is heavy, two conditions that make the handling of the machines and wagons slower than were the loading platform on private property. It is necessary to back the vehicles to the curb to load, and of course the expectation is that they will be moved as quickly as possible.

The late afternoon and the early morning orders are expected to give each wagon and truck a load, and between 8:30 and 9 the first loads are made up. The packages are placed in the vehicles in the order of delivery and this necessitates sorting and arranging while loading. The packages are checked as they are loaded and receipted for by the driver, and as delivered they must be signed for, and, if C. O. D., collection must be made as well. The loads are always valuable and in some instances represent large amounts of money. For this reason no driver has a knowledge of the route he shall deliver on until he receives orders to load, and no driver is sent over the same route twice in succession.

There are many reasons for this, but one of these is the possibility of robbery of the wagons or trucks were they to make stated trips and could be followed by men who knew the values of the loads and planned to plunder them. The loss of a single package worth hundreds of dollars might result from theft, and with a knowledge of the possibilities it has been thought wise to make every precaution that would afford protection. The drivers have been in the service of the company for considerable periods and are men worthy of confidence, but it is a lawless element that is found in every large city that the company seeks to guard itself against.

As the routes are laid out the men leave the shipping room and go to the different customers for which they have goods, making the calls in the order assigned, and the loads are made up so that they are delivered without additional handling. Thus the load as it is accumulated in the shipping room is so piled that in loading there is but little sorting necessary, as every package must be checked and accounted for previous to loading. As every delivery must be receipted for by the customer, and if C. O. D., a collection must be made, the driver must have accurate knowledge of his load from the delivery sheet. The loads vary in number of orders and the routes close to the store may be traversed much more often than those at a distance. The uptown routes, however, are with customers greater distances apart and, very generally, the orders are smaller. It naturally takes more time to traverse them.

Below Fifty-ninth street all the delivery is by wagons having capacity of approximately three tons and drawn by teams of two horse, but north of Fifty-ninth street the delivery is by the electrics, within the city, with gasoline truck haulage to Newark, South Brooklyn, the Bronx and to East New York. The first loads are made up in the morning, so that all the drivers of 16 routes are sent away by 9. The men with the longest drives may be gone the greater part of the day, and those on the lower city delivery may be absent but a half day, and possibly less. The shipping orders are made up as received and as the drivers return and report they are sent out for the second and third time, but they do not always have the capacity loads that are made up for the first delivery of the day.

The horse wagons are utilized after the morning routes have been covered for haulage from the piers and shipping terminals, or delivery to them, and in some instances these hauls are but three or four blocks. The sailing times for the water transportation lines are arbitrary so far as the river, sound and coastwise service is concerned, but there is variance with the sailings of the foreign shipping. The shipments to be made by railroad must, however, be delivered prior to stated time to insure acceptance, and to make all the deliveries, as well as the haulage, requires ample leeway, because of the innumerable causes of delay. Where shipments are to be made most frequently there is probability of extreme congestion, and this means that considerable lost time must be anticipated and looked for. Much of the export haulage is to the Bush Terminal and to the Atlas line, and for this work trucks are used.

Besides the delivery there is the haulage from the shipping terminals to the warehouses, and this means the handling of more than 100,000 packages annually. In addition there are the hauls from the local manufacturers. So far as the company is concerned it is rather fortunate in that only one of the piers from which shipments are customarily made exclude gasoline trucks. The electric machines are admitted to all of the piers without question.

In the delivery service of the company each wagon or truck has a driver and a helper, and they do the loading and the handling of the freights carried. They have customs house licenses, so that they may be admitted to the customs houses and to the piers if these are under customs supervision, as well as the bonded warehouses.

The work of the drivers making delivery to the railroad and shipping terminals is governed as well as is possible so far as departures from the store is concerned, but the last trips are more or less dependent upon the delays in the traffic. There is one characteristic of the metropolitan driver that is always manifest—his anxiety to make the last trip as quickly as possible—and with this desire uppermost in the minds of all, as may be assumed, there is an activity near the close of the day that causes traffic maelstroms at the stations and piers, and then comes a hustle through the thoroughfares for the stables or the garages. This means that conditions the latter part of the afternoon are the most unfavorable of the day, and that little useful work can be done after 5. As a rule the drivers

all report at the store and turn in their records and collections.

The city and suburban orders received during the late afternoon are made up and are placed in the shipping room so as to be ready for loading in the morning, for there is no delay in sending the route drivers away and each practically has a load for his vehicle when he reports at the store for the day. The special orders and the work aside from the deliveries are done under the direction of Superintendent Hillman.

The motor vehicles are kept at the big building in East Twenty-ninth street, which was erected as a stable for James McCreery & Co., where the upper floor of the structure is used as a garage. Here also are garaged the machines of James McCreery & Co., which are a one-ton and a two-ton General Vehicle, a three-ton Mack truck, a two-ton and two 1.5-ton Mack delivery wagons, a two-ton Reliance and a one-ton Packard wagon; a three-ton Mack truck and a one-ton General Vehicle delivery wagon of the O'Neill-Adams Company, there being 28 vehicles in all to receive attention. These are all under the supervision of a superintendent whose experience with motor machines covers a period of more than 10 years.

The garage has sufficient machine tools and general equipment to perform all necessary repair work that may ordinarily be required, and attention is given to the vehicles of the three firms as may be necessary. The purpose is to maintain all machines to a standard of efficiency, and while they are worked hard as a rule the withdrawals from service are very infrequent, although all are given overhauls as conditions may require. Careful records of the tires are kept by the wheel system, and the service of the batteries of the electric machines is recorded by mileage. The batteries are rebuilt when reduced capacity entails this work. Practically all of the work necessary on both types of machines is done in the garage, the superintendent having had experience with steam, electric and gasoline vehicles.

ELECTRIC VEHICLE MEN TO MEET.

Convention of Central Station, Manufacturing and Allied Interests at Boston May 20-21.

The first convention of the kind ever held will take place at Boston May 20-21, under the auspices of the New England Section of the Electric Vehicle Association of America, and the Electric Motor Car Club, Boston, this being a gathering of the representatives of the central stations of New England, the electric vehicle manufacturers and allied interests. The purpose of the organizers is to consider means and methods for systematically promoting the use of electric vehicles for both passenger and freight transportation, and the two days will be given over to discussion of differing proposals and suggestions that will, it is believed, be productive of large returns.

Up to the present time there has been no concerted endeavor to stimulate the utilization of electric vehicles, and it is the intention of the committee having charge of the convention to bring together the differing interests with a view of having, so far as this may be practical, a definite plan of campaign and to decide on channels that may be advantageously exploited. The sessions of the convention will take place at the Engineers' building and at the auditorium in the administration building of the Edison Electric Illuminating Company of Boston at 39 Boylston street.

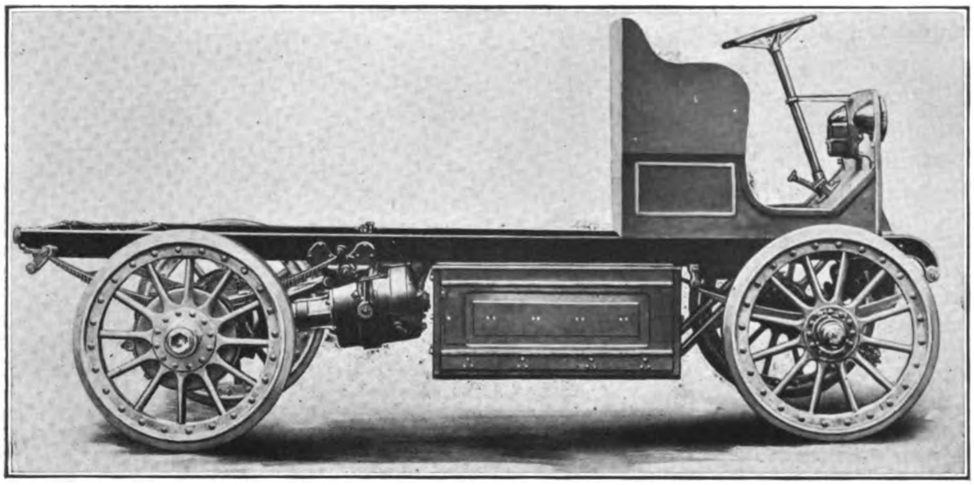
The convention is being arranged by a committee consisting of E. S. Mansfield, vice president of the Electric Vehicle Association of America, chairman; O. G. Draper, secretary of the Electric Motor Car Club of Boston, secretary, and the following general committee, which is grouped by sub-committees: Entertainment, Day Baker, chairman; E. W. M. Bailey of S. R. Bailey & Co., D. C. Tiffany of D. C. Tiffany Company; finance, Fred M. Kimball of the General Electric Company, chairman; Martin S. Fitch of the General Electric Company, J. A. Hunnewell of the Lowell Electric Light Company, S. F. Smith of the Salem Electric Light Company, Albert Weatherby of the Anderson Electric Car Company of Boston; headquarters, L. L. Edgar of the Edison Electric Illuminating Company of Boston, chairman; Robert C. Gregg of the Philadelphia Storage Battery Company of Boston, E. H. Hewin, electric contractor, Boston; invitation and attendance, J. A. White of the United States Light & Heating Company of Boston, chairman; Eugene Carpenter of the Vineyard Lighting Company, F. W. Smith of the Worcester Electric Light Company; parade, F. N. Phelps of the Baker Motor Vehicle Company, chairman; E. H. Dodge of the Dodge Motor Vehicle Company, Boston; H. S. Knowlton of the Electrical World, F. J. Stone of the Electric Storage Battery Company; programme, H. F. Thompson of the Massachusetts Institute of Technology, chairman; E. R. Davenport of the Narragansett Electric Lighting Company of Providence, George W. Holden of the Edison Storage Battery Company, M. T. Sands of the Malden Electric Company and F. D. Stidham of the New England Auto List.

Besides the sessions of the convention it is expected that there will be a parade of electric vehicles of all kinds through some of the principal streets of Boston. Parades of this character had been organized for two years with a large measure of success, but it was believed that it would be best to have the demonstration in connection with the convention. It is expected that a very large number of the owners of machines both in and outside of Boston will allow the participation of the vehicles in the parade, and it is proposed to have this event attract the attention of the public to the very rapid increase of electric cars and wagons in Boston and vicinity. The committee has extended invitations to a large number of people outside of New England and the committee on the convention programme is assured of the attendance of speakers of ability and prominence.

THE BUFFALO ELECTRIC DELIVERY WAGONS.

THE Buffalo delivery wagons, built by the Buffalo Electric Vehicle Company, Buffalo, N. Y., are of two capacities, 1500-2000 and 3500-4000 pounds, and of these the lighter machine is already offered in the market. The other type is practically ready for delivery. The chassis were designed by Guy Vaughan, assisted by H. O. Kemp, now chief engineer for the company. The designs were completed and the first series of machines were well advanced in construction previous to Mr. Vaughan associating himself with the General Motors Company.

The most important feature of the one-ton chassis is the power transmission mechanism, which has been thoroughly developed. The motor is a standard General Electric design, constructed for vehicle service, having a large overload capacity. It is suspended longitudinally from a transverse frame member by two arms, one at either side. The motor shell or housing is encompassed by a phosphor bronze band or strap on which are two trunnions which are fitted to eyes in the ends of the arms, so that the motor may be moved freely on the trunnions. The motor is coupled to the rear axle housing by a heavy webbed tube of large diameter, the assembly being rigid and with the vertical movement of the axle the motor and the shaft enclosed in the tube has a universal action that eliminates all stresses from road shock.



The Chassis of the 1500-2000 Pounds Capacity Buffalo Electric Delivery Wagon.

The armature shaft of the motor carries an external gear that engages with an internal gear on the forward end of the driving shaft, there being a slight longitudinal movement permitted, and this coupling compensates for any variance from true alignment, and besides providing for any possibility of thrust insures the transmission of motor efficiency to the full floating rear axle. The driving shaft is coupled with a double reduction gear in the rear axle housing. The motor and the axles are enclosed in a dust and oil tight casing. The design permits a straight line drive and obviates the need of universal joints, affords the necessary flexibility between the motor and axle, and relieves the members of all stress and strain.

The frame is a pressed steel channel section. 4.5 inches width and of .1875-inch stock, and is assembled with six cross members with ample gusset plates and reinforcement. The frame is 149 inches length and 40 inches width. The forward semi-elliptic springs are 39 inches length and two inches width, and shackled at the rear ends, and the rear springs, of the same type, 48 inches length and 2.5 inches width, are shackled at both ends outside of the frame. The rear axle is fitted with a heavy steel housing and the shafts and wheels are carried on Timken roller bearings. The front axle is an I section steel drop forging and has large spindles and pivots fitted with Timken roller bearings. The steering gear is a worm and sector with an 18-inch hand wheel, and with it the machinery may be turned in a radius of 33 feet. The steering column is braced from the dash to prevent vibration and consequent wear. The wheels are artillery type, of second growth hickory and are shod with 36 by 3.5-inch solid tires forward and rear.

There are two brakes, both operated by pedals, the service brake having shoes that expand within drums bolted to the rear wheels, and the emergency brake having bands that contract upon the same drums. Each shoe or band has an area of 125 square inches, this insuring absolute braking efficiency and a certain control under any circumstances. Both brakes are easily adjusted by wing nuts that are accessible by the removal of the floor boards at the front. The drive from the rear axle is through radius rods that have a swivel connection at the rear, and this eliminates all possibility of driving stress.

The controller is a continuous torque construction, and it is bolted to the frame cross members at the left side, beneath the seat for the driver. No operative parts are exposed to dust, the controller being enclosed in a compartment accessible by a door at the side of the driver's seat. There are five speeds forward and two in reverse. The resistance is a heavy cast grid, insulated with mica.

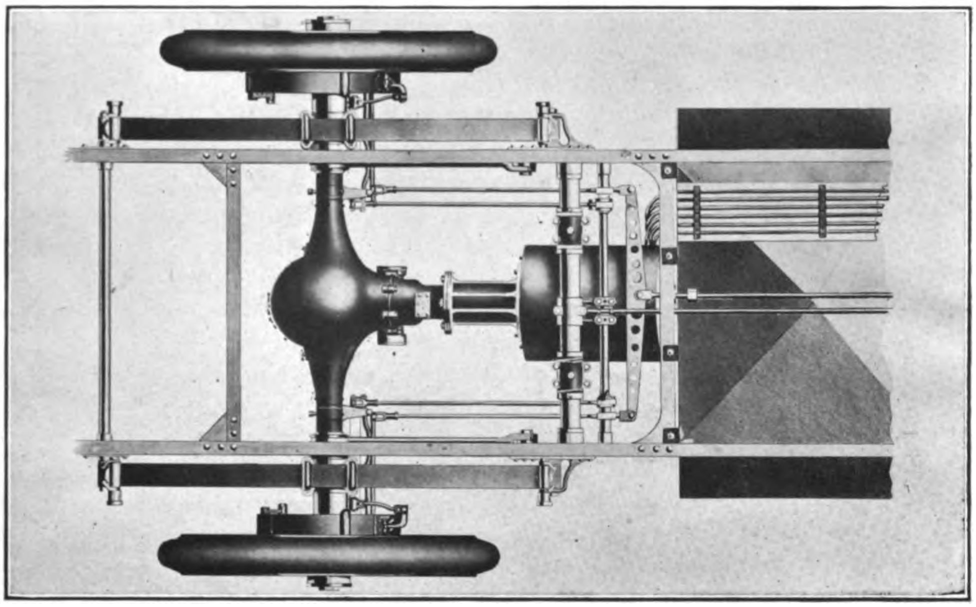
The battery cradle is underslung and it is rigidly braced at the forward end by diagonals to the side members of the frame. The top of the cradle is metal covered to prevent leakage and is pitched to insure drainage and fully protect the battery. The sides drop on hinges to the plane of the bottom of the cradle and are supported by heavy guides at either end. The battery is a 44-cell 13-plate standard Philadelphia, and the crates are set into channels, these being fixed to

the floor of the cradle, while similar channels on the sides permit the crates to be drawn out easily when the sides are lowered for examination or work. The crates are held in the cradle by a rod along the base, and by loosening a few nuts the rod may be taken out and the crates removed, or when replaced they may be secured by tightening the nuts.

The power wiring is standard flexible rubber covered cable of double the normal capacity, covered with wrapping and insulating varnish, and it is carried in a substantial runway and is well secured by separators.

Much care has been taken to insure efficient lubrication and every moving part is provided with an oil or grease cup of such size that there will be ample lubricity for any service that can be undertaken. The wearing parts are large and intended for long endur- while the means for adjustment are extremely accessible and simple. The chassis is so designed that every operating part is assembled with it, and the entire body and the seat for the driver may be removed with no other preparation than the removal of a single bolt and nut connecting the controller arm and the controller handle, and, of course, loosening the bolts retaining the body and seat.

The wheelbase is 102 inches and the tread 58 inches, and the weight of the completed chassis is 3700 pounds. The speed is from eight to 12 miles an hour and the mileage is from 45 to 60 to the battery charge. The chassis is fitted with a safety switch of open spring plunger type and it may be secured against theft by a Yale lock. The charging receptacle is a standard General Electric enclosed concentric contact type with a spring hinged cover. The chassis equipment includes a bell, tail lamp, odometer, charging plug and cable, set of tools and the controller protected by a metal box. The chassis are sold with or without body equipment, the standard body having a length of 100 inches if it extends from the driver's seat to the end of the frame.



The Motor Suspension and Rear Construction of the Buffalo Electric Delivery Wagon, 1500-2000 Pounds Capacity.

ELECTRICS IN MASSACHUSETTS.

First 15 Weeks of the Year Show an Increase of 27.8 Per Cent. Over 1913.

The Electric Motor Car Club of Boston is extremely active in promoting the use and sale of electric vehicles of all types, and has followed the registration of such machines with extreme care. The registration of service vehicles for 1913 for 15 weeks shows an increase of 27.8 per cent. as compared with 1912, the figures being 335 and 262 respectively. It is expected that there will be at least double the number registered this year, because the dealers all have orders for delivery that will very largely swell the total.

There has also been a very large increase in number of pleasure cars, for the total registered for the 15 weeks was equal to that shown by the records of the Massachusetts highway commission to Aug. 15, 1912, and the season for the sale of machines had not begun.

NEW ENGLAND'S LARGEST TRUCK FLEET.

American Express Company Now Installing Thirty Electrics at Boston.

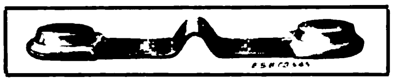
The American Express Company is now installing at its Boston branch the largest single fleet of delivery wagons and trucks owned in New England, and the last of these will be in service before the middle of May. These are all General Vehicle machines and they range in capacity from 1000-pound money collection wagons to 3.5-ton trucks. The majority of them, however, are two-ton vehicles, and will be used for general collection and delivery in the city and its suburbs. All of the fleet is equipped with the new type long distance Edison batteries.

The transformation is going on without interruption of the business of the company in any manner. A section of a large stable building in Congress street has been remodelled and changed to serve as a garage. The delivery could have been made at one time, but the company could not conveniently receive them and the machines were sent in small lots.

The Brown & Sharpe Manufacturing Company, Providence, R. I., which first purchased a General Vehicle truck, and subsequently added to its equipment three more wagons and trucks, has ordered its fifth machine, a two-ton General Vehicle wagon, which is in duplicate of one delivered to it about a year ago.

RECENT LEAD BATTERY DEVELOPMENT.

It is now two years, this month, since before this association, the first public announcement of the "Ironclad-Exide" battery was made, and it is more than two years since the first of these batteries was sold and put into regular work by others than the manufacturer, after nearly four years of development and testing by the latter. The battery was put on regular sale the following January, or the first of the year, 1911. A large demand immediately arose for the new battery, which exceeded the expectations of the manufacturer, and to meet which required increased equipment and overtime work. The immediate result, however, from the prompt installation in regular operation of several hundred sets, was to give an excellent opportunity to study practical results on a large scale, and to obtain quickly data and results, in actual service, equivalent to those of many years of work in laboratory testing. The observation of the operation of many thousand sets of batteries of this type, during the past two years, has resulted in several improvements, some of comparatively minor importance and others of sweeping value to the lead type of battery.



"Ironclad-Exide" Pillar Strap Connector.

Experience is demonstrating that the "Ironclad" construction is prolonging the life of the positive plates to about three times that of the standard flat plate positive. As evidence of this, it may be stated that in all of the several thousand sets of batteries in both commercial and pleasure vehicle service, 999 out of every thousand sets have required no renewal of the positive plates, and no renewals have been made because of any inherent weakness of the plates. This great increase in the strength of what was formerly the weakest link in the chain has brought into focus the limits of durability in other links, and has necessitated improvements in other features of the battery.

It is the purpose of this paper to touch upon some of the more important of these improvements.

The pillar strap connector or connecting link, which has always been supplied with the "Ironclad-Exide" battery, consists of a pair of lead coated copper sheets, or thin straps, upon each end of which is cast a lead alloy head for embracing and "burning" to the pillar terminal. The shrinkage of the casting upon the copper strap gives good contact, and a connector of very low resistance is the result. Complaints were received that some of the earlier batteries appeared to act in a sluggish way as though the internal resistance was high. Investigation of these batteries showed nothing abnormal in that respect until it was finally discovered that the contact between the copper and alloy, although excellent at normal temperature, was sometimes poor when hot. A method was then developed for integrally welding the copper and alloy together, which was at once adopted and which has entirely corrected this trouble.

The type of separator originally used with the first of these batteries was that which had been found so satisfactory in the regular flat plate type, i. e., a piece of vertical grained, specially treated wood. In the ordinary battery it is only necessary to provide a separator which will be sufficiently durable to last during the time when the battery is in operation between cleaning periods. In the "Ironclad-Exide" battery cleaning is practically eliminated; in addition, the life is about three times as long as that of the regular flat plate battery, and the old style of separator proved inadequate to the increased demand upon its life. The vertical grain of the wood, registering in direction with the vertical ribs on the positive plates, eventually caused the wood to split with the grain. The obvious improvement was at once made, which consisted in making the grain of the wood horizontal instead of vertical. An exhaustive investigation had, in the meantime, been started upon the characteristics of different kinds of wood, which resulted in the discovery in certain woods of a power of resisting the action of the electrolyte to a marked degree as compared with the kinds of wood formerly used for the purpose; the difference in durability is not one of minor degree, the life of the wood now used in these cells being several times that of the original kinds of wood.

An important function of the wood separator is to support the active material of the negative plate. Properly supported, as a result of the use of the new separator, the negative plates of the "Ironclad-Exide" battery should outlast the positives.

The problem of separation having been solved, the next feature to become troublesome was the formation of moss growth, which, by bridging across the tops and bottoms of the plates around the edges of the separators, caused partial short circuiting. The insurance against this trouble consists in the incasing of the top and bottom frames of the positive plates in a rubber sheath, which is then vulcanized in position directly to the tubes of which the main body of the

Vertical Grain Wood Separator.

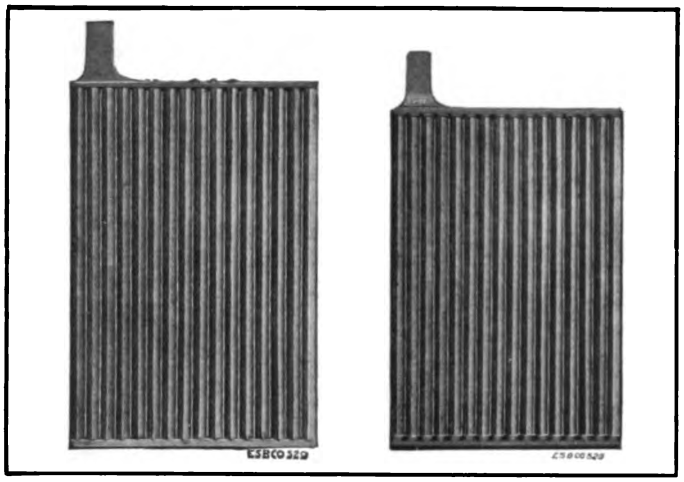
Horizontal Grain Wood Separator.

Abstract of a paper entitled "Some Recent Developments in the Lead Battery for Electric Vehicles," read by Bruce Ford, engineer for the Electric Storage Battery Company, before the Electric Vehicle Association of America, at its third annual convention.

plate consists. With the new positive plate, the exposed portion of which is nothing but rubber, an insulating material, together with the improved porous diaphragm between it and the negative plate, the insulation feature of the "Ironclad-Exide" cell is perfect and something unique.

In assembling the elements in jars there is a tendency for the workmen to drag the vertical edges of the plate along the sharp top edge of the jar. The outside tubes of the original positon plates were not calculated to withstand this particular form of abuse; as now manufactured, the outside tubes of each positive plate are equipped with an unslotted rib of rubber to prevent any breakage at this point.

The only troubles which have developed with the "Ironclad-Exide" battery have been recited above. It is our feeling that the battery, in its present form, is not only free from any troubles due to the plates themselves, but will also be free from short circuits and any necessity for taking apart during its operation, to the end of its useful life. The "Ironclad-Exide" battery



Old Type Ironclad-Exide Positive Plate. New Ironclad-Exide Rubber Sheathing Plate.

will stand up under abusive treatment, which would seriously injure or ruin a flat plate battery.

The improved "Ironclad-Exide" battery puts the electric vehicle in an advanced position. A battery is such a vital part of the equipment that an improvement in the battery becomes a corresponding improvement in the vehicle as a whole, and in the service derived therefrom.

B. Altman & Co., which conducts one of the largest and most progressive department stores in New York, has placed its third order within a year with the General Vehicle Company, Long Island City, N. Y., for electric vehicles, this order being for six 1000-pound delivery wagons, and making the total 15 for the year. It is interesting to note in this connection that this firm has used electric machines for 15 years and was the first to use such a vehicle for service purposes. The initial installation was six 500-pound Riker wagons, several of which are serviceable today. The company's garage, by the way, is one of the best in the world, there being no expense spared in its equipment.

GRINNELL ELECTRIC DELIVERY WAGON.

New Machine with Rated Capacity of 1000 Pounds and Long Battery Mileage.

The Grinnell Electric Car Company, Detroit, Mich., has begun the manufacture of a delivery wagon of 1000 pounds capacity, which is expected to have unusually large battery mileage. Aside from the battery cradle construction the machine is in every way conventional. The motor is a series wound type that is suspended from two transverse frame members, and it is longitudinally driven. The motor is at the right side of the chassis frame and at the left side of the motor is the drive shaft, the first reduction being at the motor. The driving shaft extends from the reduction gearing to the full floating rear axle, there being two universal joints in its length.

The chassis frame is a steel channel section of large size with wide webs, and it is reinforced with cross members and heavy gusset plates. The suspension is on full elliptic springs, 38 inches length and 1.75 inches width. The rear axle is a very substantial member with a housing of pressed steel, with large differential gearing and heavy driving shafts. The forward axle is an I section steel drop forging. The wheels are the artillery type, 34 inches diameter, and these are shod with 43 by four-inch tires. The wheelbase is 96 inches and the tread 56 inches.

The steering gear is an irreversible type with the column placed at the left side and all the parts and linkage are designed for long endurance. The brakes are actuated by pedals, both service and emergency brake being of the internal expanding construction, with shoes operating within drums 14 inches diameter and two inches face bolted to the rear wheels.

The battery cradle is divided, a half being carried at either side, outside of the chassis frame, the boxes being side loading. Each box contains 15 cells of 19 plates each, of the "no wash" type, and it is expected that this will afford working mileage of from 75 to 95 miles to the battery charge. The location of the battery is such that the motor and first reduction gearing is very accessible. The controller is a drum construction and affords five forward speeds of three, five, eight, 12 and 16 miles an hour, and reverse. The bearings are generally of the annular ball type and careful provision has been made for lubricating all wearing parts. The regular equipment includes an amperehour meter, odometer, searchlight in the centre of the dash, side and tail lamps, bell, tool kit, windshield, and, with an enclosed body, a dome light. The bodies supplied are the panel type, 6.5 feet length, three feet nine inches width and four feet eight inches height. The seat is designed for two passengers and the folding "lazy back" has a cross member well upholstered. The machine is known as the "All-Purpose" wagon, and it is designed for all forms of work where large radius of movement and consistent capacity is desired.

HAULING HEAVY LUMBER BY TRACTOR.

Result of Year's Experimentation with Knox-Martin Machine by James A. Potter & Co., Providence, R. I.---Comparison with Horse Drawn Equipment.

BELIEVING that while there are certain classes of haulage for which the horse is and always will be best fitted, a progressive business policy demands careful investigation of modern transportation methods, James A. Potter & Co., Providence, R. I., has been experimenting for the past year with a Knox-Martin tractor, made by the Knox Automobile Company, Springfield, Mass. The results obtained have been such as to indicate that the tractor, like the horse, has its particular field of usefulness, in which the latter cannot compete successfully.

James A. Potter & Co., has been engaged for years in the heavy lumber business, dealing only with the large, heavy timbers utilized in mill and factory construction work, etc. Fifteen years ago these timbers, many of which weigh from one to 1.5 tons, or even more, were hoisted onto running gears drawn by horses solely by manual labor. Both horses and men were worked hard summer and winter and the job was one which was termed "killing work."

This bit of history is recalled in order to show the progress that has been made. In those days labor was comparatively cheap, and horses were considered the only available means of transportation. Perhaps this situation does not differ materially from that in vogue in other lines, but it suggests the slight attention which was given to the matter of efficiency and its application to the problem of economy. The business always had been conducted in this manner and there seemed to be no other method which might be employed.

The question of easy loading was solved first. Huge cranes, operated either by motor or by hand, are now located at all points of vantage in the yards of the company on Crary street. These haul the timbers from the holds of the boats and load them upon running gears to be transported about the yards by horses. They take them from the running gears and pile them in the yard or load them upon railroad cars for shipment to distant points. When the writer visited the plant one of these cranes was unloading a boat from a southern port and loading a Bangor & Aroostook car, which had been shipped from Maine with a cargo of smaller lumber for other concerns in Providence. The interpolation is for the purpose of indicating in a measure the extent of the business done by this concern.

The cranes eliminated much of the laborious work on the part of the men, but it was still necessary to unload the timbers at the point of delivery, reference being had here to the deliveries in the city of Providence and its vicinity, at points to which it would not prove advantageous to ship by railroad or boat. This problem lies not so much in the fact that the work is hard as that it consumes time. However, with the use of horses for hauling, this time factor is not so important in itself, since the horses must be rested at the end of the haul, and often the resting extends over a much longer period than that of unloading, this depending upon the length of the haul.

When it was decided to experiment with the tractor, sufficient information was available to convince the officials of the company that with a motor vehicle maximum efficiency and maximum economy are closely related. Stated in another manner: With horses it is absolutely necessary that there shall be rest periods at certain intervals in order that there shall be proper efficiency, while since the tractor needs no rest, whenever it stops there is loss both in efficiency and economy. This necessitated devising some plan for quick unloading, as well as easy loading.

The inventor of the Knox-Martin tractor anticipated that this machine would be utilized in connection with the regular wagon equipment of the purchaser, and doubtless this plan would prove satisfactory with most lines. It will be seen, however, that the proposition as applied with James A. Potter & Co., was entirely out of the ordinary. This is the point upon which the experimentation has been made rather than with the tractor itself.

When first purchased the tractor was attached to one of the regulation wagons of the company, on which four horses had been employed. This was shod with steel tires all around, so that the only rubber utilized was on the single wheel in front. It is understood, of course, that this is the only wheel on the tractor itself, the rear end of the machine being coupled to the forward wheels of the wagon or trailer, these becoming the traction members.

The ground upon which Crary street yards are located is largely what is known as made land, and the surface has been badly cut up by the heavy haulage thereon for years, so that it is in the form of a powder. Each spring, and after very heavy rain, this powdered soil becomes a veritable quagmire in places, and it was found that the steel shod wheels sank into it to such depth that it was with difficulty that the tractor could haul its load. In this connection it is necessary to state that the machine is capable of handling a load equal to that hauled previously by two four-horse teams.

Because of these extremely heavy loads it was found that the horse wagon was not exactly suited to the requirements, and a contract was let to Jas. Blake & Son, Buffalo, N. Y., for a special wagon. This was of heavier construction throughout and was so built as to carry the load in the most advantageous manner. For instance, the loading space between the wheels is

practically five feet, making it possible to so pile the timbers that greater tonnage can be carried without securing an abnormal height. It was found that it was desirable to provide wheels of comparatively large diameter, because of the necessity for turning the forward, or traction members, under the wagon in making turns on the road, and because it would prove impossible to have the rear members lower than those in front and secure the distribution of the load which was considered proper. Attention also is drawn to the means provided for affording additional protection to the spokes as shown in the accompanying illustration.

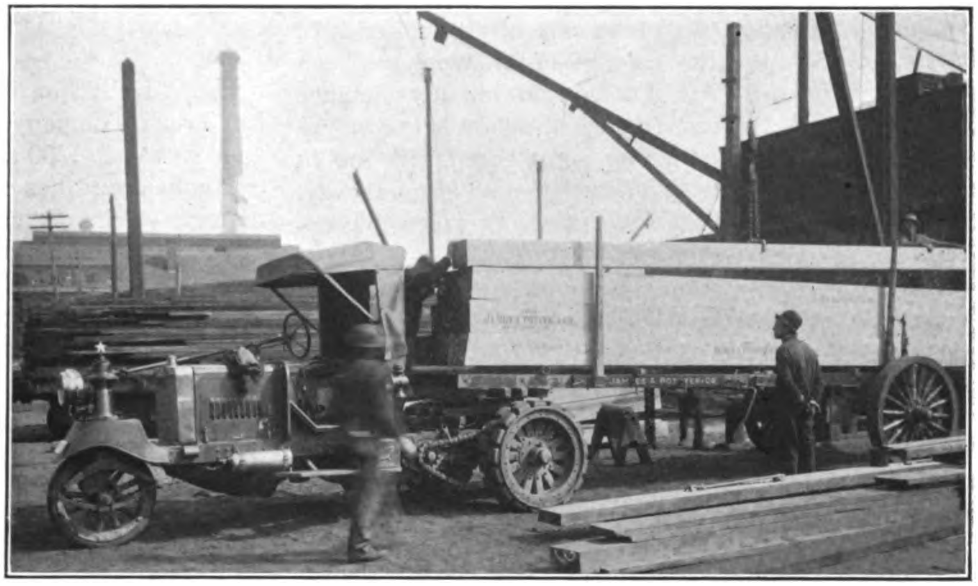
The new wagon also was shod with steel tires all around, the width being six inches. This provided for better traction, but the result was still not just what was desired. Another change was made about three months ago, the traction wheels now being shod with Goodyear block tires. Although they have been run several hundred miles they show no appreciable wear and the officials of the company feel that they have solved this problem satisfactorily. The equipment has yet to find a mud hole from which it has been unable to extricate itself with ease, and it may be added that the driver finds greater comfort in riding.

To return to the matter of unloading: When the new wagon was purchased, A. E. Potter, one of the members of the firm, evolved a plan of utilizing rollers. It will be understood that the loading platform is constructed of metal, with suitable cross frame members. The roller at the rear is provided with a lock which holds it in place, and with a ratchet to which a handle is fixed. The load rests on this roller, but not on the others, which are distributed along the chassis frame, if such it may be termed. When it is desired to unload the timbers, the ratchet handle is operated, the rear roller bringing the load backward until it catches the other rollers in turn and the whole is deposited upon the ground in a pile, as the tractor assists by hauling the wagon out from under it. By this means it is possible to complete the work within 10 minutes.

Mr. Potter says the tractor can do the work of two four-horse teams. This statement needs further amplification. A four-horse team can haul 4000 feet under favorable conditions. This lumber is figured at the rate of 4.5 pounds to the foot, which means that four horses can haul about nine tons. The tractor has hauled 15 tons. It took a load measuring 6875 feet from the yards in Providence to Plainville, Mass., a distance of 20 miles. This figures out at 30,937.5 pounds at 4.5 pounds to the foot. Obviously, there must be some other means of making comparison.

The four-horse team hauls its average load at an average speed of three miles an hour. The tractor travels at between eight and nine miles an hour. If the load is made ready the night previous, four horses can start out at 7 in the morning, go to Attleboro, Mass., a distance of 16 miles, and return to the yard at 6 in the evening. With the tractor it is possible to begin loading in the yard at 1:30 in the afternoon, go to Attleboro and be back in the yard at 5:30. Assuming that two four-horse teams were doing the same work as the tractor, it would take 11 hours to accomplish what the tractor can do in less than four, because with the horses the loading was done the day before.

A sample day's work for the tractor is as follows: Left the yard at 7:20 in the morning, for Lonsdale, R. I., eight miles; returned, eight miles; went to Central Falls, R. I., eight miles; returned, eight miles; went to Woonsocket, R. I., 16 miles; returned, 16 miles; arrived at the yard on the last trip at 5:45 in the afternoon. Thus in 10 hours and 25 minutes, it delivered three loads and covered 64 miles. Of course, time must be taken out for dinner in any case. Two four-horse teams might have made the same mileage, but could not carry the same tonnage.



Illustrating Method of Loading Heavy Lumber by Cranes and the Equipment Used with Knox-Martin Tractor by James A. Potter & Co.

As a matter of fact, there is no basis upon which to formulate an exact comparison, for the reason that the tractor has not been worked steadily. It is used only in what is termed emergency work. Some of the time it has not been available, because of the experimentation which has been made with reference to the wagon. There has been no delay on the part of the tractor itself. Mr. Potter thinks its average daily mileage while in service has been between 30 and 40, but this is due to the manner in which it has been utilized.

It should be stated that all the members of the firm are enthusiastic horsemen. The decision to purchase the tractor was reached only after much discussion,

and then only because it was felt that the demands of modern business were such that provision must be made for the future. The investment, therefore, has been considered in the light of an experiment, and the tractor has not been used when it was deemed practical to work horses. In other words, the horses were considered as a necessary equipment which must be worked to its fullest capacity, and the tractor was held to be available only in emergencies.

By an emergency is meant any haul covering long mileage and extremely heavy loads, any haul where quick delivery is essential, where the roads are not of the best, when the weather conditions are unfavorable for horses, etc. The last named situation is worthy of special mention. With horses, even where the work is confined to the yards, in the heated portion of the summer it is impossible to employ these draft animals steadily. After each short haul it is necessary to take the horse into the shade and apply water to its head and shoulders. The tractor has not been employed to relieve horses in the yard hauls, but in the heat of summer it is expected to take care of all deliveries of any appreciable length. Enough of this work has been done to indicate to Mr. Potter that for any distance inside of a mile the tractor does not show an economy over horses, but beyond that point the figures are in favor of the machine. This applies in a general way, the heated period of the summer being a possible exception.

Because of the manner in which the tractor has been worked there has been no way of determining just what it costs. Roughly, Mr. Potter estimates this at between $12 and $13 a day with an average daily mileage of 40. He says the gasoline consumption figures out at about three miles to the gallon. Two men are employed, not because one could not handle the machine and its load, but because the driver feels the need of an assistant in view of heavy load carried and the unusual features in turning corners, etc. Probably this arrangement will not be continued indefinitely. At present it is an outgrowth of the original plan, when two men were needed to unload the timber before the installation of the rollers. Since it is admitted that but one man is needed, the interests of economy would suggest that it was hardly proper to include the second man's wages in the daily cost estimate.

A comparison of the investment represented by the two equipments is as follows: Tractor, $3250; wagon, $400; extra rubber tires, $400; total, $4050. Eight horses, $2500; two wagons, $300; total, $2800. Beyond stating that in his opinion it costs something less than 60 cents a day to care for a horse, or $4.80 for the eight, Mr. Potter says he has no available figures on the cost of operating horses. The animals, like the tractor, are kept in a building at the yard and no charge is made either for barn rental or garaging. He must have some means for determining to his own satisfaction what it costs to maintain horses, since he otherwise would be unable to make a statement with reference to the relative economy of the two. And he adds that if the firm had work for it to do he would not hesitate to purchase another tractor, albeit he holds that he has not finished his experimentation with the first. He says:

"Most people who attempt to give comparative figures, fail to overlook anything on the horse side of the account, while they may not be so particular about the truck. I would like to give the horse a chance. I believe that the truck has a legitimate place, but I do not believe in trying to make it do a horse's work. It is the same way with this tractor. We don't know just what it can do, but we are safe in saying it can replace two four-horse teams. I believe it has its legitimate place and we are experimenting with it in order to learn just what that is."

MOTOR TRUCK ON THE FARM.

E. S. Kelly Believes It Will Have an Important Bearing in Agriculture in the Future.

E. S. Kelly, president of the Kelly-Springfield Motor Truck Company, Springfield, O., maker of Kelly trucks, has a 1200-acre farm about nine miles from Springfield and has made some study of the utility of motor vehicles in connection with farm work. He comments upon his observation as follows:

"The motor truck will have a great influence in opening up farm land which has hitherto been inaccessible because of its distance from any kind of transportation. There are millions of acres of good farming land in various parts of the country which are lying idle because they are too far away from transportation. A one-ton Kelly truck can cover from 12 to 15 miles an hour, carrying capacity loads over ordinary country roads.

"A team with a heavy load is limited to about six miles an hour or even less. On the whole, a motor truck will cut the time required to carry produce to market to about one-third of what it is with horse drawn vehicles. No one but a farmer who is compelled to make a 20-mile haul to market can appreciate what this means. It will give the farmer far more time to spend on his farm and will effect numerous savings in other ways. The next 20 years will bring about a wonderful development in agriculture and the motor truck will be responsible for a large share of this advance."

The recent motor truck show in Motor Square Garden, Pittsburg, Penn., opened with a huge attendance. One of the largest truck shows ever held in that city was the promise of the promoters and their expectations were more than fulfilled. Among the makes on display were the Dorris, Baker, Locomobile, Packard, Koehler, Pathfinder, Peerless, Pierce-Arrow, Pope-Hartford, Mack, KisselKar, Hewitt, Reo, Speedwell, Shelton, White, Waverley electric, Vulcan and others.

Municipal Service Equipment

SEAGRAVE TYPE D COMBINATION.

An Arrangement That Gives a Complete Fire Department in One Installation.

In an effort to provide an installation that shall give the smaller city or town complete fire protection as well as afford an economical outfit for the larger city, the Seagrave Company, Columbus, O., has introduced its type D combination hose wagon, chemical engine and tractor shown in an accompanying illustration. As may be noted, this not only places at the disposal of the department a rapidly moving vehicle capable of taking care of small fires in their incipiency, but at the same time brings to the scene of the blaze ample equipment to fight the most stubborn fire.

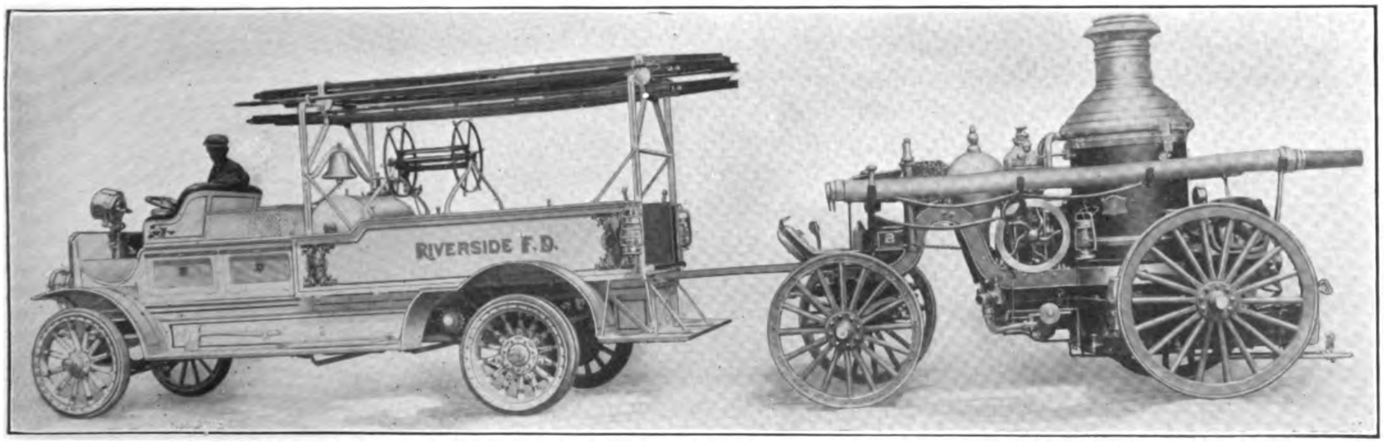
It will be understood that the steam pumping engine is the regulation horse drawn apparatus, which may already be owned by the municipality. The two stand together in the station, a jockey pole on the rear of the tractor being made fast to the splinter bar of the steamer by clamps, and a coupling pin connecting the other end to the power chassis. When a run is made the steamer is dropped off at the hydrant or cistern, and while the hose is being laid from the pumping engine to the fire, the chemical engine is expected to hold the blaze in check or place it under control as it is able.

Considered as a separate piece, the power chassis is equipped with either a four-cylinder 50 horsepower or a six-cylinder 80 horsepower motor. The transmission gives three forward speeds and reverse, and final drive is by double side chains. The wheels are of heavy artillery type with steel hubs, utilizing 36 by four-inch single tires in front and 38 by 2.5-inch dual members in the rear. The wheelbase is 158 inches, tread 62, length over all 20 feet two inches, width six feet six inches, body dimensions, 10 feet by four feet two inches.

The equipment includes a chemical tank of from 20 to 50 gallons capacity, 200 feet of chemical hose, acid bottles, pressure gauge, hose reel, bypass with 2.5-inch hose connection, from 1000 to 2000 feet of regulation fire hose, 12-foot Seagrave trussed roof ladder with folding hooks, 20-foot Seagrave trussed extension ladder with rope hoist, lanterns, axes, crowbar, two three-gallon extinguishers, etc.

The car is built stronger than the standard type and is so constructed that it may withstand the extra duty imposed upon it by hauling the horse drawn equipment. It is maintained by the company that while care must be taken by drivers at first in rounding corners, etc., they soon become accustomed to handling both pieces and corners may be turned at an average speed without difficulty.

Installations of this character are being used successfully in a number of cities, both large and small, and the experience with them is said to have indicated a decided economy. The tractor is expected to displace at least four horses, two for the engine and two for the combination wagon, or if it be one of the larger engines, it will take the place of five horses.



Seagrave Type D Combination Hose Wagon, Chemical Engine and Tractor, as Installed with Horse Drawn Steamer.

EXPERIENCE WITH AUTOMOBILES.

Figures in Watertown, N. Y., Indicate a Saving of Practically $600 in Six Months.

Hundreds of dollars are being saved the taxpayers of Watertown, N. Y., each year by the installation of motor driven apparatus in the fire department. An automobile for Chief Fred Morrison was purchased three years ago and last year a motor combination chemical, hose and pumping engine was added. The latter has more than demonstrated its superiority over the old time fire engine. Following is the cost of the horse drawn and the motor apparatus for six months:

Horse Drawn.	
Maintenance of four horses	$228.00
Wages of two drivers	373.00
Coal for heater	6.00
Repairs, etc	10.00
Total	$617.00
Motor Driven.	
81 gallons gasoline	$11.34
15 gallons oil	5.75
Five pounds transmission grease	.60
Total	$17.69

This is a saving of practically $600 in six months,

Cartercar Pay Car in Service with City Treasurer at Detroit.

or about $1200 a year. The chief's automobile, which has been in constant use nearly every day for three years, having been run 3500 miles up to January, has cost 19.5 cents a day for maintenance. During the past year $56.80 was spent for tubes, patches and replacements of tires; $88.13 for repairs to axle, gas lights, spark plugs, etc.; $38 for repainting.

DETROIT'S PAY CAR SUCCESSFUL.

Plan Found to Make for Economy as Well as Safety in Handling City's Funds.

It will be remembered that the officials of Detroit determined to test out a plan of sending the city paymaster to the various departments and jobs where workmen were employed, instead of sending the money by messenger as previously. It had been found that the messenger was in danger of being attacked and robbed, and it was decided to secure an automobile, specially designed, which should amply protect the funds and those in charge.

The Cartercar Company, Pontiac, Mich., was commissioned to build the car, utilizing plans prepared by the city officials. This machine has now been in service sufficiently long to demonstrate its thorough practicability. It has been found not only to eliminate all risk, but it enables the paymaster to pay off the same number of men in considerably less time. Sixty men were paid in just 10 minutes at the time the accompanying photograph was taken.

FIRE DEPARTMENT ECONOMY.

Pittsburg Man Estimates Entire Equipment Can Be Motorized at 50 Per Cent. Profit.

John H. Dailey, director of the department of public safety of Pittsburg, Penn., is strongly in favor of motorizing municipal fire departments and as a result of his personal experience with the efficiency of motor fire apparatus, he ventures the prediction that within five years there scarcely will be a town of any size in this country in which the major portion of their equipment will not be motorized. Mr. Dailey gives some interesting figures, taken from the experience of the fire department of Pittsburg. He says:

"The actual figures compiled from the operation of what motor apparatus we have show that when we have our department completely motorized we will save the first year almost double what the entire motorization will cost us. It costs approximately $600 a year for each piece to maintain the horse drawn apparatus. On motor propelled fire wagons the cost of maintenance is approximately $55 a year for each piece. This figure is taken from the cost of operation of our chemical and hose wagon at the No. 26 engine house, which is a fairly busy one; more so than the average fire company, so that all around this figure is a fair one on which to base calculations. Included in this cost is the expense for repairs made necessary through two collisions. We operate a total of 131 pieces in our fire department and keep constantly on hand 25 extra horses, which is equivalent to 12 pieces more, making a total of 143 pieces. This does not include the runabouts and horses of the chief engineer and district chiefs. This makes a comparison that looks something like the following:

143 pieces of horse drawn apparatus at $600 a year	$85,800.00
143 pieces of motor propelled apparatus at $55 a year	7,865.00
Balance in favor of motor apparatus, a year	$77,935.00
Add loss through death of horses, etc., about	7,000.00
Total	$84,935.00

"A very large item of economy that must be added to this is that brought about through the reduction of men in the service. This reduction, it should be understood, will not be caused by the discharge of any of those now in the service. The fire department loses every year through various causes such as illness,

death, voluntary resignation because of engaging in other business and retirement on pension, 40 to 50 men. It will take about three years to completely motorize our department, which means we will lose in that time from 120 to 150 men now members of the department. When the latter is completely motorized, with the same number of pieces of apparatus now used, we will need 116 men less, as there are that many who do nothing now but take care of their horses. This reduction in the force will mean an additional saving to the city of approximately $143,000, and this added to the saving in the cost of maintenance makes a total of $227,000.

"When the entire department is motorized we will be able to dispense with about 12 engine houses now in operation without decreasing the efficiency of the department. This, of course, will be made possible by the increased radius of motorized apparatus, amounting to perhaps 300 per cent. The city will have 12 valuable pieces of property for sale and it is fair to assume that we will receive at least $500,000 for all the property sold. Add this to the saving in maintenance and decrease in wages and we have a total of $727,000. The cost of motorizing the department will be approximately $500,000, leaving a net profit of over 50 per cent. on the transaction."

NEWS OF GENERAL INTEREST.

LaFrance in Manchester, N. H.—A new fire truck has been delivered to Manchester, N. H., by the American-LaFrance Fire Engine Company, Elmira, N. Y. The machine carries 250 feet of ladder equipment, 50-gallon chemical tank, two pony extinguishers and general supplies.

Recommends Additional Equipment—Fire Commissioner Charles P. Nutter of Malden, Mass., in his annual report, asks that an appropriation be given for the purchase of more motor fire apparatus and recommends an aerial truck and a pump. It is claimed the apparatus would save the original cost in four years.

Seagrave Proves Satisfactory—Two more automobile hose wagons will probably be ordered by Davenport, Ia., according to an announcement recently made by Fire Chief Denger. It is said that the sentiment of the business men is so strong for additional fire protection that the city council has decided to secure the new machines. The efficiency of the motor tractor on the aerial truck and the hose wagon, made by the Seagrave Company, Columbus, O., has been proven to the satisfaction of Chief Denger.

Four Miles in Ten Minutes—A two-story house just over the state line at Plaistow, N. H., from Haverhill, Mass., was recently burned with a loss of $3000. The town of Plaistow has no fire apparatus and Haverhill was asked for assistance. The automobile truck made the run of four miles in 10 minutes and its arrival was a distinct relief to those who were fighting the flames, having formed a bucket brigade. Although the burning house was doomed before the firemen arrived, the Haverhill men prevented the flames from spreading to other buildings in the town.

Grand Rapids to Buy Vehicles—The officials of Grand Rapids, Mich., have decided to purchase three more motor vehicles; a wagon for the assistant marshal, a supply automobile for superintendent of the fire and police signal systems, and a runabout for the private use of the superintendent. An expert will also be engaged to attend to the mechanical details.

More Apparatus for Springfield—The board of aldermen of Springfield, Mass., has passed an order appropriating $24,000 for the purchase of additional motor apparatus for the fire department. Besides this amount the fire commissioners have $12,000 that was provided for the same purpose in the municipal budget, making $36,000 that will be expended this year. The commission contemplates the purchase of a third electrically propelled aerial ladder truck, a motor pump, a combination hose and chemical truck, and possibly one or two other pieces.

Lynn Department to Be Motorized—That the Lynn fire department, Lynn, Mass., will be equipped entirely with automobile apparatus within two years is the prediction of Commissioner of Buildings H. C. Bayard. The approximate cost of such a change would be $50,000. There are 15 fire stations in the city.

Knox Exceeds Specification Requirements—Stoneham, Mass., has placed in service a new Knox automobile fire truck, made by the Knox Automobile Company, Springfield, Mass. It is equipped with two chemical tanks of 35 gallons each, 1200 feet of hose and 30 feet of ladders. The specifications called for a machine to carry 11 men, but there are accommodations for 20.

Milwaukee Secures Two KisselKars—The city of Milwaukee, Wis., has purchased two additional KisselKar 1500-pound motor wagons for use by its water department. This makes a total of seven KisselKar wagons in the service of that city, four in the water department, two police patrols and a car which does runabout duty for the public library. They were made by the Kissel Motor Car Company, Hartford, Wis.

In the Market—Some of the cities in the market for motor fire apparatus are: Findlay, O.; York, Penn.; Hartford, Conn.; Lynchburg, Va.; Pittsburg, Penn.; Westfield, Mass.; Marshfield, Ore.; Springfield, Ill.; Fond du Lac, Wis.; Pasadena, Cal.; Lawrence, Mass.; Elmira, N. Y.; Joliet, Ill.; Franklin, Penn.; Houston, Tex.; Carlisle, Penn.; Hamilton, O.; Millbury, Mass.; Harrison, N. J.; Troy, N. Y.; Fall River, Mass.; Louisville, Ky.; Anaheim, Cal.

COST ACCOUNTING IMPORTANT.

A Factor That Makes for Elimination of Horses in Favor of Mechanical Transport.

Cost accounting is one of the important factors needed to bring about the absolute elimination of the horse from modern transportation, according to G. W. Bennett, vice president of the Gramm Motor Truck Company, Lima, O., maker of Gramm trucks. "If every man who now uses horses in the delivery of merchandise will keep an accurate account of the cost of his work," says Mr. Bennett, "it will be only a short time before the motor trucks will be adopted to the complete exclusion of animal haulage." He adds:

"The greatest trouble truck salesmen encounter in their work is to convince the man who still sticks to horse and wagon methods of transportation that he is paying an exorbitant price for his service. The percentage of merchants who keep an accurate accounting of their delivery system is very small and it is safe to say that every one who has adopted this businesslike method has forsaken the horse and installed motor trucks. We find this true in our business at any rate. As soon as a Gramm salesman can convince a horse owner that he should figure costs, he is practically certain of making a sale, for invariably he is able to convince the prospect, by the figures already prepared on the prospect's own business, that the motor vehicle will prove an economy in transportation methods. This is especially true in these days of high cost of living, which applies to the maintenance of horses no less than to humans."

KISSELKAR IN MAIL SERVICE.

Works 17 Hours a Day in Collection Department of St. Paul Postoffice.

Following the sale of 15 KisselKar motor wagons, made by the Kissel Motor Car Company, Hartford, Wis., to the United States government for parcel post service after a thorough and severe test at Washington, D. C., the Kissel company has delivered a car of the same model for use in the mail service at St. Paul, Minn. The mail in that city is collected by contract, this relieving the postoffice of the expense of buying and maintaining the equipment necessary to conduct the work. The contractors are held to very rigid terms, penalties being exacted for delays in making scheduled time. For this reason caution was exercised in the selection of a motor wagon, several makes and types being tried out before a decision was reached.

The St. Paul machine is in continual daily use from 8:30 in the morning until 1:30 the following morning. At 8:30 it starts on a tour of the outlying business houses and factories. From 11 in the morning until 7:30 in the evening it tours the downtown districts and from 7:30 until 1:30 it covers the residence sections. Drivers and carriers work in relays.

TRUCKS IN THE PHILIPPINES.

Report of the Public Works Department Indicates Superior Efficiency Under Unfavorable Conditions.

E. Lascaris, New York distributor of De Dion-Bouton trucks, has received an interesting report from the Philippine Islands concerning the performance of certain vehicles purchased by the public works department about three years ago. The report specially bearing on this topic is that of Warwick Greene, director of public works, in which he says:

"During the year this line carried over 19,000 passengers without accident or injury to any of them. Considering the conditions under which this automobile service is maintained, the result is considered remarkable and may be attributed to the strict discipline maintained and to following railroad practise in running the automobiles in trains and regulating the traffic with regular block signal system with gates, gatekeepers and telephones.

"The main reliance of the line is placed on 18 motor trucks, of which 17 were especially built for service on the Benguet road and one for use in Baguio. During the year 5161 tons were carried under the direction of the automobile line, for the greater part by De Dion-Bouton trucks, although a portion was by bull carts and mule teams. Our experience has shown us where considerable saving can be made in operation and there will be a substantial net surplus at the end of the year."

The distance from Camp No. 1 to Baguio is 22 miles and the difference in altitude between Camp No. 1 and Baguio is 5800 feet. It is, therefore, a steady climb over a winding road, and in a tropical climate, which furnishes a severe test of truck efficiency.

NEW YORK'S CLOSED PIERS.

All of the Docks of the Metropolis Except 13 Now Open to Gasoline Trucks.

The most complete information relative to the restrictions with reference to the use of motor vehicles on piers in New York, is to the effect that there are now but 13 lines that refuse to permit access to their terminal to gasoline machines. All of the piers are open to electric vehicles, and those that are closed to other forms are the American Line, Atlantic Transport Line, Anchor Line, Austro-American Line, Cunard Line, French Line, Fabre Line, Hamburg-American Line, Holland-American Line, Italian Royal Mail Line, North German Lloyd, Scandinavian-American Line and White Star Line.

The Atlas Line to Europe and all the Central and South American lines are open, as well as all the river and sound steamer and the railroad piers. This is a very large gain for the gasoline trucks and it is probable that the number of open piers will be materially increased in a comparatively short time.

FOREIGN TRUCK NOTES OF INTEREST

FIRST AID PUMPING ENGINE.

Brief Description of Recent Addition to Fire Fighting Equipment of Paris.

As is more or less well known the fire fighting service in Paris, France, has undergone a complete transformation, automobile apparatus having entirely supplanted horses. It may be added, however, that changes are still taking place, the latest being that of installing what is known as first aid pumping engines. One of these is shown in an accompanying illustration.

The city is divided into 12 sections, each having a barracks and stations, the company of firemen being quartered in the former, while the latter are served by a detachment from the barracks and relieved every 24 hours. The so-called regiment of firemen is under the command of Col. Cordier, who conceived the idea of restricting the larger pumping engines to certain stations and of supplying the others with the first aid apparatus.

These are light vehicles so designed as to reach the scene of the blaze quickly and put out the fire before it has developed serious proportions. The chassis does not differ materially from the usual truck chassis produced by Delahaye. The pump was designed by Farcot. The same four-cylinder motor operates both.

It will be noted that a reel of small hose carrying a nozzle 10 millimeters in diameter is located directly back of the driver's seat in the space sometimes occupied by the chemical hose in the combination wagons in this country, and serving a similar purpose in a measure. This is connected with a reservoir, directly underneath, with a capacity of about 100 gallons of water. The size of the nozzle permits direct attack upon the point where the blaze commences.

When the apparatus reaches the scene of the fire a lever is so placed that the power of the motor is used for driving the pump, which is a multiple-cylinder unit said to have a capacity of 7500 to 8000 gallons an hour. A suction tube is joined to a three-way valve which permits the discharge of the pump into the reservoir, the suction of the pump and pipes from the reservoir, the directing of the pump onto the fire or the filling of the reservoir without the aid of the pump.

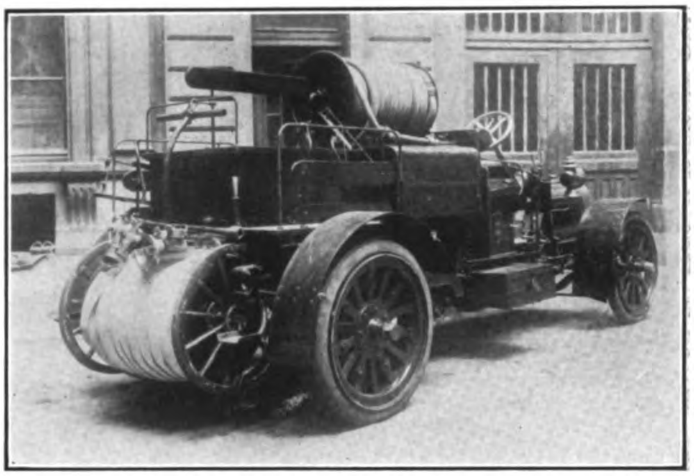
It will be understood that the part played by the first aid apparatus is similar to that of the chemical engine, in that as soon as the vehicle reaches the fire the pump begins playing upon the blaze, utilizing the water in the reservoir until such time as the suction tube can be connected. It is estimated that this will be sufficient in at least one-third of the fires, while in a majority of others the first aid will be able to hold the blaze in check until the arrival of the larger pumping engines. At the rear is carried a movable reel of regulation hose which may be used in case of an emergency.

ELECTRIC REFUSE CART.

German Municipal Authorities Experimenting with New Three-Wheeled Vehicle.

Gebhardt & Harhorn, Ltd., of Berlin-Schoneberg, Germany, has supplied an interesting three-wheeled refuse cart to the municipal authorities of one of the suburbs of Berlin. A feature of the vehicle lies in the fact that the body is removable, so that the chassis is available for other uses if desired. The machine is electrically driven.

The motive power is provided by means of an electric motor supplied with current from 20 150 ampere-hour cells. This is built integral with the front wheel



Delahaye-Farcot First Aid Pumping Engine Used by Fire Department in Paris, France.

and is of the direct current type. The armature rotates outside of the fields, and transmits power to the road wheel through a 5:1 reduction gearing. The car can be run forward or backward with equal facility, the reversal of the battery current being effected by means of a patented switch especially designed for use on this type of vehicle. The maximum speed is between 25 and 30 kilometers an hour, which is equivalent to 15-18 miles, and it is stated that a distance of 150 kilometers (93 miles) can be covered on a single charge.

The body which is at the rear is tipped and unloaded by drawing up a lever arranged at the right of the driver's seat. An automatic device for sanding the streets also is provided, the distribution of the sand being accomplished by an electric motor. This car is used for the collection of refuse accumulating in the streets after regular cleaning hours.

IMPROVED LOADING DEVICES.

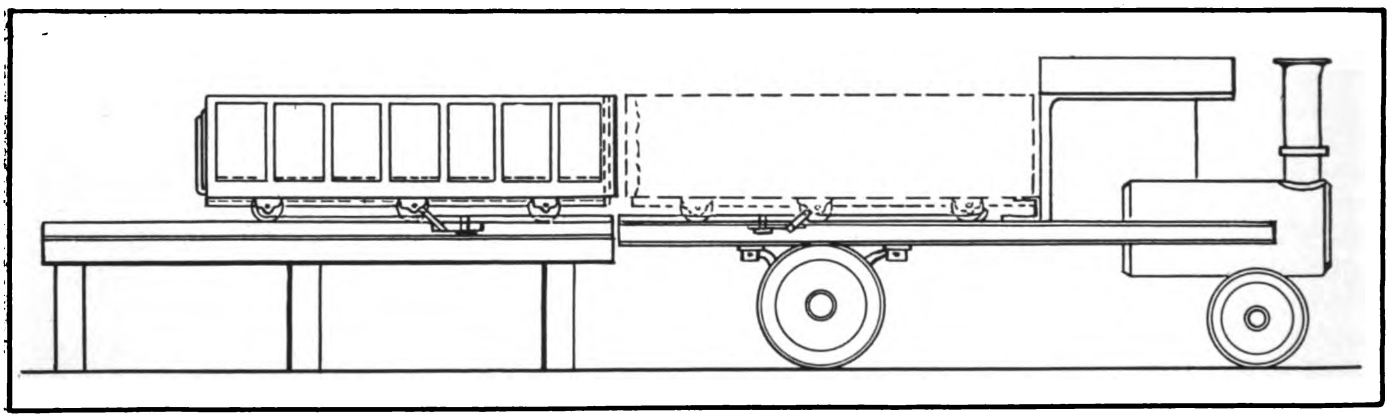
British Motor Vehicle Users Beginning to Study Problem in Scientific Manner.

Although it is generally regarded that motor transportation received careful consideration abroad before the industry realized its possibilities in this country, it is somewhat significant that the manufacturers have not assisted users to the same degree that has been true in America. It is only recently that many users of commercial motor vehicles in Great Britain, for instance, have begun studying some of the problems which have interested both manufacturers and owners alike in this country. While it is true that a few producers have made effort to provide suitable loading and unloading equipment, it would appear that in many instances the owner has been left to work out his own solution.

F. M. Smith, managing director of the Associated Coal Consumers, Ltd., of London, has only recently installed a system of interchangeable bodies for the handling of coal at the company's wharves, which has excited some little comment among motor vehicle users in England. In the first place, it must be known that for the supply of coal to private consumers in London it is necessary to pack it in bags, each of which is required to carry two hundredweight. It is this fact which makes it impossible to dump coal in bulk from the wharf to the wagon bodies. With public institutions, factories, etc., coal can be supplied in bulk without the necessity for separate sacking.

Mr. Smith found by experimentation that the average time needed for loading a wagon and trailer exceeded two hours. Under this arrangement the company's five-ton steam wagon was able to handle but three 10-ton loads a day. Obviously, there was decided need for some system which should reduce the waiting time, if the mechanical transport were to become a paying investment.

The interchangeable bodies are fitted with flanged wheels, and the wagon is provided with rails to take these, a simple locking device preventing the body from moving on the rails once it has been fixed in place. The principle involved is similar to that which has been utilized in this country and its main features are presented in an accompanying illustration.



Illustrating General Principle of Quick Loading Device for Use with Steam Tractor by Coal Concern in London, England.

In a recent demonstration, an empty body was taken from the wagon and replaced with a five-ton load in 4.5 minutes. Extra trailers are utilized, making it unnecessary to transfer the bodies on these. In the demonstration to which reference is made, the entire time consumed from the instant the wagon arrived at the wharf until its load had been replaced and the loaded trailer had been picked up was six minutes. This arrangement already has saved about 4.5 hours a day on the loading time, making possible two additional deliveries.

ARMY SUBSIDIES IN AUSTRIA.

Some Conditions That Will Have to Be Met by American Exporters.

The Austrian government, like the governments of Germany, England, France and Russia, provides motor trucks for army use by a system of subsidies to the private purchasers of a specified type, on condition that in case of necessity they shall be subject to the call of the military authorities. The subsidized vehicles are subject to call annually at the time of the manoeuvres and for the duration of hostilities in case of mobilization of the army, during which service owners receive extra compensation.

It is evident that the character of the roads of Austria and nearby countries determined the specifications of the truck open to subsidy. They are notable for their light carrying capacity, and the grade requirement, 16 per cent., is higher than for any country in Europe except England. The smaller size of vehicle necessarily means that a greater number would be required for the same work, but the mountainous configuration of Austria and the bad roads of adjacent countries to the south would render light weight and grade climbing power of prime necessity.

The government subsidies and specifications also determine largely the type of motor truck for general commercial use and thereby limit the field for imports. Buyers naturally prefer machines which earn subsidies to imported vehicles, even if the latter are cheaper and perhaps better. It would seem, therefore, that Austria would be a favorable market only for American light

delivery wagons for local use, in connection with which there would be no question of government service or subsidy, unless American makers could conform to subsidy conditions and induce the government to admit their vehicles to the war office lists. The specifications of wagons for such service in Austria are as follows:

Speed, 16 kilometers (9.9 miles) maximum, average 10 kilometers (6.2 miles) an hour, capacity for a grade of 16 per cent., 35 horsepower on 800 revolutions, rubber tires, fuel supply for 350 kilometers (217 miles), chain or cog drive, wheelbase of motor wagon 3,600 millimeters (11.8 feet), of trailer, 3,300 millimeters (10.8 feet), loading platform, 2,800 millimeters (9.1 feet) long, 1,800 millimeters (5.9 feet) wide; sides, 600 millimeters (1.9 feet) high with extra boards for sides 500 millimeters (1.6 feet) wide; fuel, benzine (gasoline) or benzol. The wagons should have a maximum carrying capacity of 3,000 kilos (6,614 pounds), the trailers of 2,000 kilos (4,409 pounds) capacity. Traction wagons to be qualified for subsidy must be made wholly or partly in Austria-Hungary. The purchasers of such wagons may, by placing them on the government registry, receive a subsidy at time of purchase of 4,000 crowns ($800) and 1,000 crowns ($200) a year for five years, which under certain conditions may be extended one year, in all 9,000 to 10,000 crowns ($1,800 to $2,000), and the motor truck remains for five to six years at the call of the government.

SELF-CONTAINED MOTOR PLOW.

Interesting New Agricultural Machine Placed in the Market by German Manufacturer.

In the Stock motor plow, produced by the Stock Motorflug, Berlin, Germany, is found an interesting self-contained agricultural machine. By self-contained is meant that the plowing attachment is connected permanently to the frame of the vehicle instead of being hauled by the latter as a separate implement. Perhaps the most striking feature is the large diameter of the two driving wheels, fitted with deep paddles for increasing their grip upon the soil. These are arranged in the centre of the whole vehicle, which is supported from the main axle and practically is balanced in a horizontal position.

The motor is a four-cylinder unit of 42-50 horsepower, which is carried with the radiator at the front of the main frame. Ignition is by Bosch magneto, and the carburetor is designed to operate on gasoline, benzol or other similar fuels. Power is transmitted through a clutch and change speed gearing, and finally by spur gears meshing with large diameter gears on the main axle. The whole of the transmission is enclosed in dust tight casings. Three speeds are provided for working under normal plowing conditions, while a fourth is added for particularly heavy soil.

Steering is by means of a hand wheel and irreversible gearing, which controls the movements of the single wheel pivoted at the rear and on the left side of the plowboard. This rear wheel is provided with a central flange to prevent side slipping and the steering movements are communicated to it through a long diagonal rod fitted with the usual type of ball joints. The end of the plow frame can be raised or lowered by means of a rack and pinion gear operated by a long endless chain taken from a sprocket on the end of a horizontal shaft fitted with a handle in front of the driver. Thus it will be seen that one man may drive the machine as well as attend to the six plows.

GENERAL NEWS FROM ABROAD.

Hospital Disinfecting Machines—The Magdeburg corporation in Saxony, Germany, has decided to purchase two automobiles each for the municipal hospital stations in the old city and the suburb of Sudenburg, which will be used for the purpose of transporting disinfecting materials.

Public Service Cars in New Zealand—Four companies, with an aggregate capital of some $150,000, have been organized in New Zealand for the purpose of exploiting the possibilities of commercial motor vehicles for public service corporations and others. A service already has been proposed for Timaru.

Japanese War Officials Experimenting—Announcement is made that for some time past officials of the Japanese war department have been experimenting with motor vehicles for army purposes in the vicinity of Tokio. A special committee has been appointed by the government for consideration of the problem.

Fire Apparatus in India—According to the Civil and Military Gazette of Lahore, India, the use of motor fire engines has been making considerable headway during the past five years, vehicles of this kind now being found in Calcutta, Bombay, Madras, Delhi, Lucknow, Allahabad, Hyderabad, Rangoon and various other large towns and cities.

Trucks for Italian Army—The Italian military authorities have been granted an appropriation of practically $2,000,000 for the immediate purchase of 700 motor vehicles. The order has been divided between the following makes: Fiat, 300; Zust, 200; S. P. A., 100, and Isotta Fraschini, 50 to 100. The last named are to be largely of the delivery van type, capable of carrying loads of about 1.5 tons. All the larger vehicles are to be fitted with steel tires. A test near Rome, culminating in a 2000-mile run, is to be given the different types in order to determine the modifications needed before the bulk of the order is filled.

New Commercial Car Accessories

Pyrene Fire Extinguisher.

The Pyrene fire extinguisher is produced by the Pyrene Manufacturing Company, 1385 Broadway, New York City, and is adapted for garage service and to be carried on the machine. It is very compact and weighs approximately five pounds. It extinguishes fires by the formation of an elastic non-poisonous blanket, which separates the flame from the burning material. It contains neither acid, alkali, salts nor moisture and will not injure any material with which it is brought into contact. The liquid is not employed under pressure, will not freeze and may be utilized on all classes of electrical fires without danger to the user. Pyrene is a double acting hand pump, easily operated, and the discharge is under the control of the operator at all times.

Amico Spark Plug.

A new spark plug presenting practical features has been brought out by the American Ignition Company, Inc., 319 Adams street, Dorchester, Mass. The construction of the Amico plug differs from that of conventional design in several particulars and the most striking point is the provision made for expansion of the porcelain, which material is utilized for insulating purposes. The porcelain is approximately an inch in diameter, making for extreme strength and durability and it should withstand severe usage. The metal shell of the plug is sturdily constructed and is provided with the usual hexagon, but the interior has a decided taper. This is for the purpose of compensating for the expansion of the porcelain and if such action occurs it is on an incline. The packing employed is asbestos, which is compactly wound around the porcelain, and the gasket is .75 inch high, making a perfect joint as well as one that is gas tight. The porcelain is retained at uniform pressure, by a vamped ridge. One of the qualities of the plug is the electrode on the shell, it being liberal in size and not easily sprung out of position through careless handling. The main electrode extends through the centre of the porcelain and the tapered end of the latter provides ample room for the gases to clean the points.

Dayton Airless Tire.

The Dayton airless tire is produced by the Dayton Rubber Manufacturing Company, Dayton, O., and is held to combine the resiliency of the pneumatic and the durability of the solid shoe. One of its several advantages is that it is puncture and blowout proof, as it does not depend on air for its resiliency or for maintaining its shape. It is constructed on the same principle as an automobile wheel in that there are piers or spokes of rubber and an annular rib of straight cut fabric and rubber. The spaces between the solid sections allow displacement of the rubber when the tire encounters an obstacle and eliminate jouncing or vibration. The piers of rubber are so constructed as to unite with and become a part of the casing and cannot be dislocated therefrom. The Dayton airless tire mileage guarantee is liberal.

Planhard Carburetor.

Springs, cams, levers, etc., are noticeable by their absence in the Planhard carburetor, made by the Planhard Manufacturing Company, 1790 Broadway, New York City, with factory at Kokomo, Ind. It is of the concentric type, the float chamber surrounding the mixing chamber. Proper vaporization of the fuel and the operation of mixing it with the air is accomplished by a double concentric air and mixture construction. The fuel nozzle is in the centre and is entirely surrounded by the fixed or constant air tube. The auxiliary air is admitted through a series of ball valves, which are seated in holes in an adjustable screw plate at the bottom of the auxiliary air tube. These seats vary in size, but the balls are of the same diameter and are lifted from the seats progressively as more air is required, the ball on the largest seat being raised first. This is held to eliminate fluttering and to make for a smooth operating motor. The spraying nozzle is cup shaped and when the engine is inoperative, this fills automatically with fuel to within a short distance from the top. This priming device makes for easy starting. The float chamber is provided with the conventional flooding device. Greater efficiency from the motor and economy of fuel are among the qualities of the Planhard.

Burn-Boston Batteries.

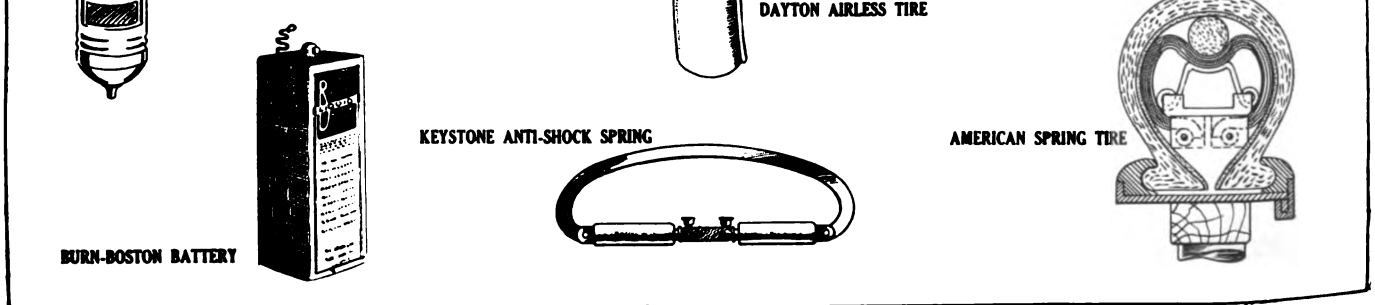
A battery having all the conveniences of the dry cell in that its size and shape are similar is the Burn-Boston, made by the Burn-Boston Battery & Manufacturing Works, 19 Doane street, Boston. It differs from the usual cell in that the electrolyte is a liquid and that it will not dry up. It is not affected by moisture or dryness nor will it deteriorate when out of service for a considerable period. The cells are securely sealed, preventing loss of the electrolyte, and are not impaired by vibration, etc. The connections are very durable and practical, the zinc member comprising a special wire equipped with a terminal, while the negative member is sturdy. The most prominent quality of the battery is its long life. Instances are quoted in support of this contention by the company. A special offer is being made and a booklet will be forwarded on request. The voltage of the battery is standard.

American Spring Tire.

The American spring tire is manufactured by the American Spring Tire Company, Chicago, and is held to combine the advantages of a solid and pneumatic shoe. It comprises an outer casing enclosing the resiliency members, which consist of a circular strip of solid rubber, resting on a number of springs, fitted with a form of roller bearing, and a housing is provided for both members. The springs are also reinforced by a bridge. Brass friction leaves are utilized between the primary springs and the outer casing is fitted to a clincher rim.

Keystone Anti-Shock Spring.

The Keystone Spring Works, Philadelphia, is marketing the Keystone anti-shock automobile spring, which is applied to a vehicle in the same manner as a conventional full elliptic spring, being clipped to the axle and body. The top frame is of a special steel with the two cylinders of Shelby seamless tubing. Springs are utilized inside the cylinders and these include an oil shock absorber, actuated by a ball valve in the end of the piston connection. The lubricant is retained by a special stuffing box and provision is made for replenishing the supply. It is claimed that road shocks are completely absorbed and that the car will ride as easily empty as loaded.



Some New Accessories, Including Pyrene Fire Extinguisher, Amico Spark Plug, Dayton Airless Tire, Planhard Carburetor, Etc.

THE A B C OF MOTOR TRUCK IGNITION.

Part IX--The Bosch Timer-Distributor and Its Functions--Make and Break Systems and the Principles of Operation---Types of Igniters and Their Characteristics---Magnetic Plugs and the Arrangement of Components.

By C. P. Shattuck.

SUPPLEMENTING the previous discussions of devices for distributing and synchronizing the high-tension current, the Bosch timer-distributor illustrated at Fig. 46 is of interest in that it presents many practical advantages. Although designed for installation with motors having two sets of spark plugs, and to be utilized in connection with a magneto, it can be employed when the only source of current is a battery. With both the magneto and battery the system provides two independent circuits controlled by one switch.

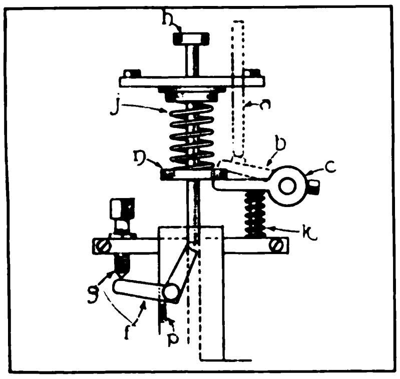


Fig. 44—Make and Break System Utilized with Two-Cycle Single-Cylinder Motors.

The battery and distributor system comprises a combined coil and switch and the timer-distributor, the latter being shown at Fig. 46 A and B. It is attached to a shaft operating at camshaft speed by means of a sleeve a and locked by a taper bolt. The base plate c is provided with two ball bearings upon which the sleeve rotates, and attached to the sleeve shaft is a steel cam k, having as many projections as there are cylinders. The circuit breaker lever w is held against the cam by a spring m and normally the platinum points n and o are in contact. The short platinum point n is secured to the lever, while the screw member o is screwed into the insulated block p, and is adjustable and locked by a nut.

It will be noted that the block p and platinum point o are insulated from the base of the timer, and are connected to the primary winding binding post r. The circuit breaking lever, however, is grounded. The positive terminal of the battery is connected to this post and when the contact points are together the current flows from the positive terminal of the battery to the brass block p, lever w, ground, switch terminal, metal plate in coil, through the primary winding of the coil, switch plate, and to the negative terminal of the battery.

Operation of Timer.

When the cam rotates, a projection separates or breaks the contact of the platinum points, interrupting the flow of the primary current, and the reaction results in the production of a high-tension current in the secondary windings. The operation of the timer is similar to that of the commutator previously described, differing only in that the break of the circuit is accomplished by separating points and not by the wipe method.

The distributor is mounted above the timer. The distributor rotor b carries a brass tube, and a carbon brush s is also included, this projecting laterally. In its rotation the brush sweeps a cylindrical cavity formed in the distributor plate or disc e. A contact is provided for each cylinder, one of the members being shown at f. Another carbon brush h is fitted, this being employed to convey the high-tension current from the coil to distributing mechanism. One of the terminals to which is connected the cable leading to the spark plug is shown at r. Synchronization is secured through the mechanical breaker or interrupter, the principle of which is the same as that utilized with magnetos.

Make and Break Ignition.

One of the simplest forms of ignition is the low-tension, sometimes designated as "make and break." A low voltage source of electrical energy is utilized; in the average case about five or six volts, but the resistance of the circuit is such that from one to two amperes, or in some cases as high as five, flow when the circuit is closed.

At Fig. 45 are shown the essential components of a low-tension system of the simplest type. They comprise a battery, switch, insulated stationary electrode, movable electrode, wires and coil. The last named dif-

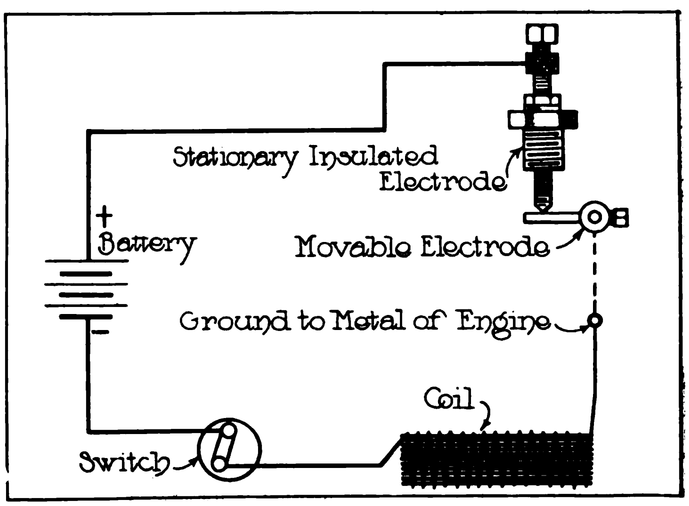

Fig. 45—Illustrating Components and Circuit of Low-Tension Make and Break System of Ignition.

fers from the induction coils previously outlined in that it comprises a number of turns of coarse wire wound around a soft iron core. It is termed a "kick,"

"reactance," "intensifying," etc., coil, and it is of the induction type, but the increase of voltage of the battery current passing through it is only momentary.

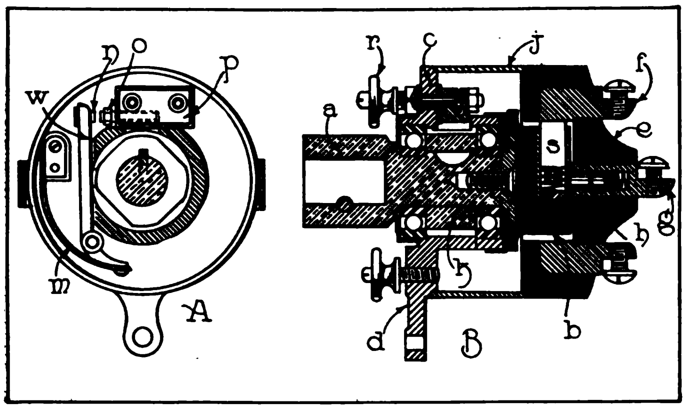

Fig. 46—Bosch Distributor and Interrupter: A, Showing Contact Points and Method of Breaking Primary Circuit; B, Sectional View of the Timer-Distributor.

With the components arranged as illustrated in the drawing, the circuit is closed, the current flowing from the positive terminal of the battery, for example, to the stationary electrode. The latter is screwed into the cylinder of the motor and carries a metal pin, which is insulated from the metal of the engine by suitable material—usually mica. The movable electrode being in contact with the metal of the motor—in practise it is located in the combustion chamber of the cylinder, also touching the pin of the stationary electrode—current will flow as the circuit is completed or closed. Upon the electrodes being separated by mechanical means the breaking of the contact causes a spark to pass between them, igniting the mixture.

The system is very simple, eliminating as it does the vibrator and timer, but it is not free from trouble in that the mechanical parts are subject to wear. There is also more opportunity for loss of compression around the movable electrode. It is utilized largely on marine or stationary two-cycle engines and the arrangement of the mechanism controlling the timing of the spark with the marine type is shown at Fig. 44.

The stationary and movable electrodes are designated by a and b respectively, and these members are shown in contact. On the outside of the cylinder is a sliding rod p, actuated by an eccentric rod attached to the motor shaft. On the plunger h is mounted a thimble n, which is held in contact with the movable electrode by a spring, the tendency of the spring always being to maintain the electrode in a horizontal position. A spring k, however, is placed under the electrode, but its tension is considerably less than that of the other member, being utilized to force the movable electrode up into contact with the firing pin.

On the slide rod is an angular dog f, pivotally mounted, and this member is tripped by an adjustable screw mounted on an extension of the cylinder. Normally the tension of the spring j on the thimble n prevents the movable electrode from making contact with the firing pin, but upon the slide bar rising, the dog f compresses the spring j until the electrodes are in contact as shown by the dotted lines. A further movement of the slide bar causes the dog to be tripped by the screw g, resulting in breaking the contact between the electrodes through the energy of the spring applied to the thimble and movable electrode. The separation of the electrodes occurs at the completion of the compression stroke, and with some types of make and break mechanism the screw member g may be raised or lowered by hand to bring about an earlier or later break.

Other Forms of Igniters.

The system described is suited to the two-cycle motor, but is not adaptable to the four-cycle engine because of the increased number of strokes. While it would be possible to employ it by utilizing reduction gears, etc., to obtain the break at the proper instant, the mechanism would be too complicated to be practical.

The make and break system of ignition formerly was favored by several makers of motor cars, but it has been supplanted by the jump spark and magneto. As there are a number of converted machines the operation of the older system will be of value to the novice not familiar with the application of the principle.

At Fig. 47 B are shown the components of an igniter. The low-tension current is led to the insulated busbar a, which has a knife switch b, the latter providing means for cutting out the cylinder if desired. The igniter plate c is made cone shaped to fit the cylinder and is secured by three bolts to a corner of the combustion chamber over the inlet valve. It carries an insulated anvil, or fixed electrode f, and a hammer or movable electrode d. The latter is L shaped and includes an arm or lever e, which is actuated by a lifter rod n carrying a spring h. The rod is given a vertical movement by the rotating cam on the camshaft. During the upward movement the hammer and anvil are in contact, but upon the cam completing its movement

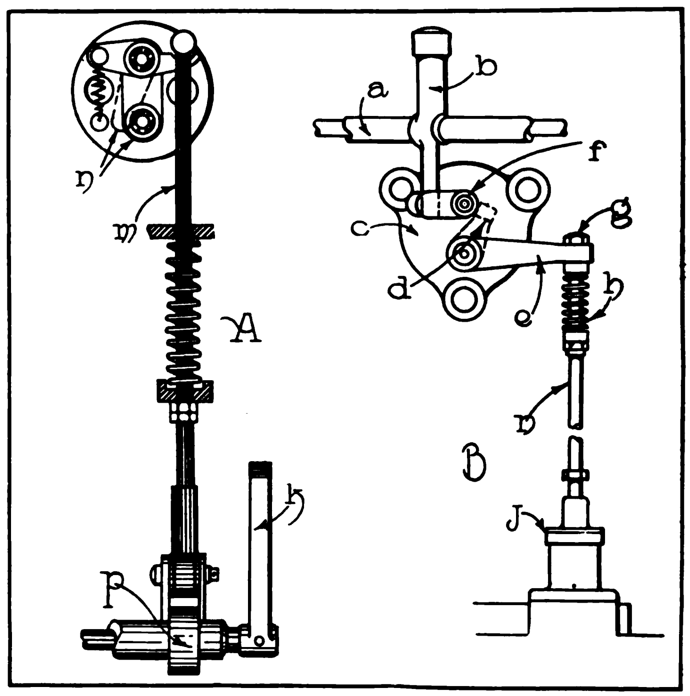

Fig. 47—Forms of Igniter or Make and Break Systems: A, Bosch Low-Tension; B, Igniter Mechanism Formerly Employed on Well Known Makes of Pleasure Car.

the lifter rod falls, this action being accelerated by the spring. Consequently the contact is broken and a spark is created much in the same manner as it is ef-

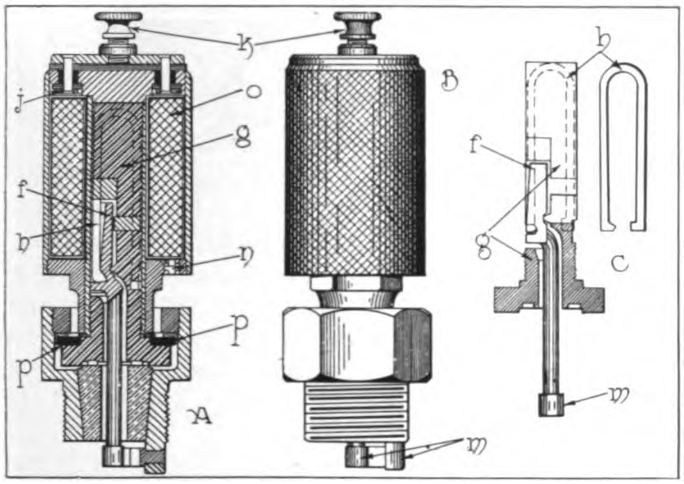

Fig. 48—Bosch Magnetic Plug System: A, Sectional View of Plug; B, Showing Contact Members Actuated by Electricity Generated by Oscillating Armature of Magneto; C, Components of the Make and Break Device.

fected in the marine type of make and break.

The method of obtaining the break in the Bosch low-tension system is of interest as a low-tension magneto is utilized and differs from those employed with high-tension systems of ignition. The breaker or interrupter mechanism is shown at Fig. 47 A and is adaptable to automobile and stationary motors with mechanically operated tappets. Two types of magnetos are constructed and the electricity is produced by a stationary armature, the current being interrupted in the explosion chamber of the cylinder by mechanical means. The magnetos are suitable for one and multi-cylinder engines with more than 350 revolutions a minute and maximum efficiency is claimed for the system.

Principle of Make and Break System.

The principle of the make and break mechanism is similar to the systems described and the construction is such that the cone shaped member inserted in the cylinder is gas tight. It carries an insulated pin contact with which is made by an interrupter arm, these members being indicated by n in the drawing. Normally the parts are together, but upon their separation a spark occurs.

The movable electrode or interrupter is actuated by an outside tappet m, the latter being operated by a cam p. The timing of the spark is effected from the camshaft of the motor and a timing lever k permits of late or early ignition.

Low-Tension Magneto.

The magneto utilized with the system is shown at Fig. 48 and its construction and operation will be described briefly as the subject of magnetos will be taken up in detail in logical sequence. As previously stated, the armature is stationary and because of this the electricity can be utilized directly, the ends of the armature winding being connected with terminal screws and without the aid of carbon brushes, etc.

By referring to the drawing it will be seen that the armature is located between the pole shoes of the double magnets, and that between the armature and pole shoes is an iron sleeve, the rotating member. The beginning of the winding is connected to the armature core. The end leads through the spindle insulation of the rear armature spindle to a terminal, being connected to this by means of a cable connecting screw. The sleeve is carried by the two end plates and lubrication is effected by felt wicks.

During each revolution of the sleeve, four sparks are produced, it revolving at half the speed of those having a rotating armature. A maximum current is secured four times each revolution, one after each 90 degrees. The period during which the contacts may be broken to obtain the spark varies through an angle of 30 degrees measured on the magneto shaft. The correct time for breaking the contact is when the sleeve is a few degrees past its horizontal position. The speed of the sleeve varies according to the different motors. On one, two and four-cylinder units it is driven at camshaft speed; with three-cylinder engines at three-quarter speed, and on six-cylinder motors, 1.5 times.

The current generated is carried from the terminal by an insulated wire to the pin of the sparking flange, through the interrupter arm and motor frame, back to the body of the magneto, the circuit being completed only when the points are in contact.

Magnetic Plug Ignition.

A system making for simplicity in that the make and break of the circuit is accomplished electrically is the Bosch magnetic plug ignition or Honold system, illustrated at Fig. 49. It is designed for single-cylinder engines utilizing gas, gasoline, kerosene or spirits, and not exceeding 250 revolutions a minute. The usual mechanical contact breakers, etc., are eliminated, the interruption of the circuit being effected by the current itself. The latter is generated by an oscillating motion of the armature of the magneto between the pole

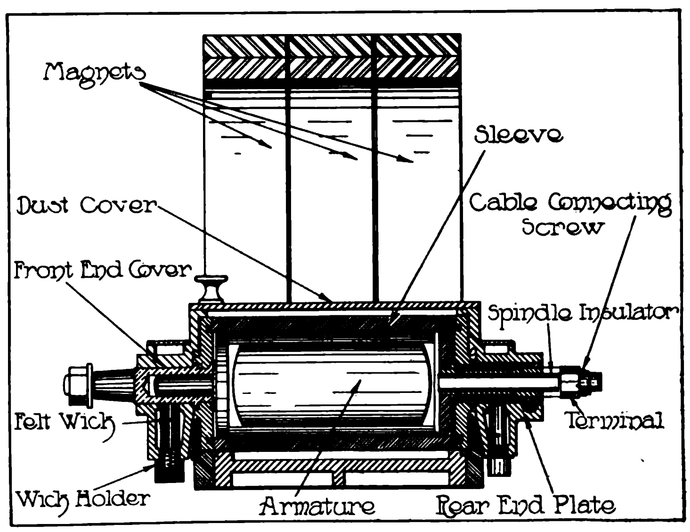

Fig. 49—Sectional View of Bosch Low-Tension Magneto Utilized with Make and Break Device Shown at Fig. 47 A.

shoes of permanent steel magnets. The movement is produced by two springs operated by a bell crank lever from the camshaft of the motor.

The assembled magnetic plug is shown at B and is screwed into the cylinder in the conventional manner. It comprises a plug body having a hexagon nut and thread, a coil body and the arrangement shown at C. The contacting pieces, electrically operated, are illustrated as m at B.

Components of System.

The arrangement of the sparking components is shown at C, these comprising an interrupter lever f, a pole piece g and a U shaped spring h. The electrodes m are forced into contact by the spring h as one end of the latter presses against the back of the interrupter just inside of a steel knife edge. The spring has a very slight movement and is well protected from the heat of the combustion of the gases. The contact pieces m are mounted on the interrupter lever f and the plug body, and are separated only at the time of sparking, at which moment a current flows through the coil o.

To accomplish this action, one end of the winding is in connection with the current carrying ring j, while the other is electrically connected by means of the screw n to the body of the coil. The coil, pole piece and the interrupter are insulated from the plug body by a steatite cone and mica washers p.

The operation of the system is simple. Reference has been made to oscillating armature of the magneto. This is moved out of its resting place through an angle of 30 degrees at the moment of ignition, and is pulled back to its original position by balance springs. This movement is brought about through the operation of the camshaft of the motor by means of a rotating thumb piece or other suitable device. For this purpose a double bell crank lever is attached to the cone of the armature spindle, to the horizontal arm of which are fixed the balance springs, whereas the vertical portion of the bell crank lever is actuated by the attachment on the camshaft.

By the movement of the bell crank lever a tension is brought on to the springs, which are released again at the moment the camshaft thumb releases the bell crank lever. The springs thus force the magneto into its original position again and by this movement a current is produced in the winding of the armature. The current passes from a terminal on the magneto through an insulated cable to the terminal k on the plug, through the coil of the latter and returns through the interrupter, motor and magneto body to the armature winding. The magneto has no retard or advance, but this may be accomplished mechanically on the motor itself.

(To Be Continued.)

Ed. Note—The next installment will deal with mechanical generators of electricity, defining the principles involved and their application in practise.

The H. T. Jenson Company, Sheridan, Wyo., has sold two Nyberg 1.5-ton trucks to the largest wholesale grocery concern in that city.

FEDERAL DEMONSTRATES VALUE.

Helping Horse Wagon up Long Grade Results in Sale of Four Machines.

While demonstrating a Federal truck to a prospective customer over Fillmore street hill, San Francisco, Cal., P. S. Nichols, general manager of the Standard Motor Car Company of that city, Federal agent on the Pacific Coast, overtook a two-horse truck that was striving vigorously to make the grade, but was unable to do so with its heavy load of furniture. A rope was secured and the Federal acted as aid and easily towed the team and load the remaining two blocks to the summit of the hill. The teamster was so impressed by this performance that he related his experience to his employer.

Several days later, Mr. Emmons, president of the Emmons Draying Company, called on Mr. Nichols and investigated the Federal trucks. After going over the subject of its pulling qualities and its cost as compared with horse delivery expense, Mr. Emmons placed an order for a truck. Since trying out his first purchase, Mr. Emmons has repeated his order and now has four Federals in his service. He is now one of the most enthusiastic truck advocates on the Pacific Coast.

KELLY TRUCK PROVES EFFICIENT.

One of the First Water-Cooled Models Shows Little Wear After Covering 21,000 Miles.

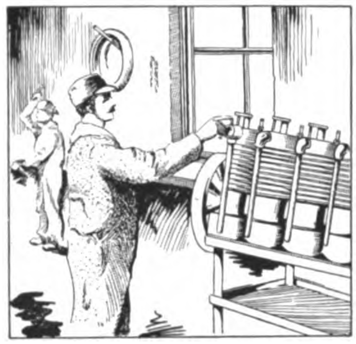
A three-ton Kelly truck, made by the Kelly-Springfield Motor Truck Company, Springfield, O., in the service of the Wagner Transfer & Storage Company of that city, has covered more than 21,000 miles and is now running as well as ever. Jacob Wagner, president of the company, is authority for the statement that today his Kelly truck is the easiest running vehicle he has owned in several years.

The chassis contains one of the first water-cooled engines built by the Kelly-Springfield company. Before it was sold to Mr. Wagner this vehicle was put through 18,000 miles of strenuous factory and road tests. It was then taken down and failed to show wear in any place. The machine was then reassembled and sold to Mr. Wagner. Since then it has covered more than 3000 miles in the service of his company.

The Rochester Hille Mining Company, Rochester, Nev., has purchased a Knox-Martin tractor, which is being used to haul ore from the Codd lease on Nenzel mountain over the Nixon ore road to the railroad siding 12 miles distant. New ore carrying wagons have been built at San Francisco and it is planned to draw several in one train with the tractor as motive power.

HINTS·FOR·PROPER MAINTENANCE

A Department for the Owner, Driver and Repairman.



THE high cost of fuel is an important factor in the operation of commercial vehicles and makers of carburetors are devoting their efforts to produce a device which will permit of the use of heavy fuels. The difficulty experienced with kerosene is in starting a cold motor, but the Air-Friction Carburetor Company, Dayton, O., maker of vaporizers bearing that name, announces a new model known as B. It is constructed to utilize fuels heavier than gasoline and the company states that of the number in actual service, in some instances two parts kerosene are employed to each part of gasoline, while others use the fuels in equal proportions.

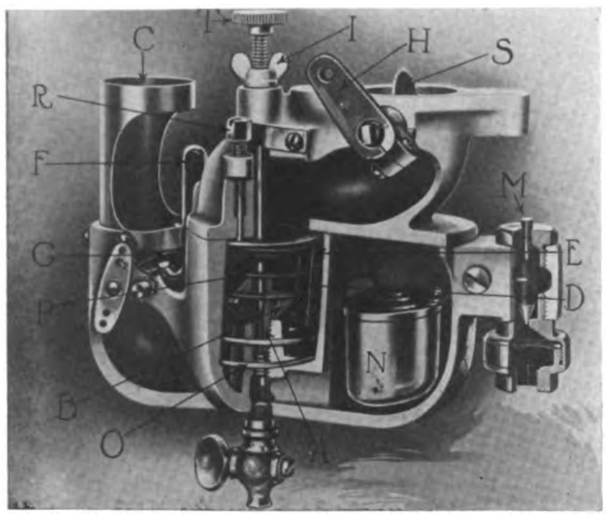
A sectional view of the new carburetor is presented in an accompanying illustration with each component lettered to make clear its application. The use of kerosene is held to be possible by the large wetted surface presented by the spray nozzle A, which retains the mixture in a film between two discs B, .01 inch apart. The air is taken through one source C, being previously warmed by passing around the exhaust pipe, and being conveyed to the vaporizer by the usual flexible metal tubing. As the heated atmosphere enters it lifts a truncated valve D, which is enclosed in a valve cage E, thus providing the motor a proportionate volume of mixture at all speeds.

As the heated air passes the spray nozzle A it becomes saturated with the fuel, forming a gas instead of a spray, and is drawn into the cylinders without vacuum being created. The maker maintains that it is superior to a spray full of globules, as the latter are difficult to lift and allow a large percentage of the mixture to condense.

To overcome the difficulties of starting with a heavy fuel a U shaped plunger F is operated by closing the air butterfly valve G, pushing down the valve cage E and its truncated valve D, to restrict the air. This enriches the mixture required for starting. Upon gradually releasing the air butterfly valve G the cage E resumes its natural position. The velocity of the incoming air is dependent upon the valve opening of the throttle. The fuel adjustment is secured by loosening the small winged, thumb jam nut I and rotating the needle T. The adjustment of the air is by the small hexagon nut R. The bowl and top are constructed of aluminum and the float needle M of brass with an imported alloy. The float N is of drawn metal. The only spring utilized is that at O, it being employed for pushing the valve into place when the air butterfly member is released, and the small one P is entirely enclosed to prevent tension loss. All levers, nozzle parts, etc., are of brass.

CLEANING THE RADIATOR.

Those who removed the anti-freezing solution from the radiator and did not clean the cooler will do well to give this member that attention it deserves. The opening of the petcocks and draining off the old fluid and refilling with fresh water will not serve as there

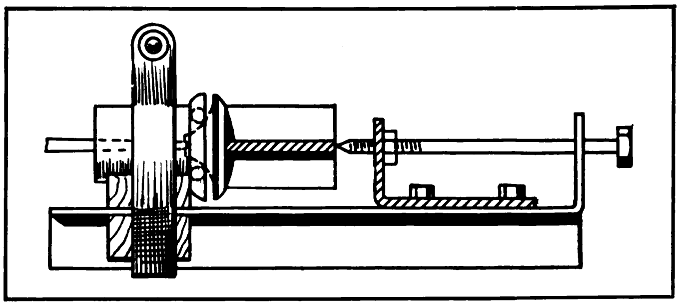


New Air-Friction Carburetor, Designed to Employ Heavy Fuels Mixed with Gasoline.

is more or less boiler scale which forms and which is deposited as a fine, brick colored powder. This accounts for that reddish colored water when the cooler is emptied.

The circulation system should be cleaned because of the scale created by hard water. While some make a practise of changing this frequently the best method is to take as many common washing soda crystals as will dissolve in water, the fluid equalling the amount used in the system. After emptying out the old water, pour in the prepared solution and run the motor for a considerable period. Some take the machine out for a couple of hours.

Next drain off the soda solution and refill with fresh water and again operate the motor. If upon removing the fluid it shows discoloration, refill with clean water and again run the motor. Another method is to open the petcocks and with the engine running feed fresh water into the radiator, just enough to replace that which is running out.



A Valve Trueing Tool That May Be Constructed Easily and at Slight Expense.

The exterior of the cooler should receive attention as the accumulation of dirt between the fins lowers its efficiency. By using a hose and playing a mild stream from the back of the cooler the dirt may be loosened easily. The magneto should be covered during the operation and the water should never be directed at the front and through the cooler to the motor.

HOME MADE VALVE REPAIRING TOOL.

The condition of the valves and seats is an important factor in proper maintenance of the motor and as these parts are subject to wear it may be necessary to true them. Usually the work is carried to the expert because of lack of proper facilities, but it may be accomplished by the owner or driver, provided he has suitable tools.

It is a simple matte: to make a valve trueing machine and in an accompanying illustration is presented a design which may be constructed easily. The bed is made out of a piece of three by three-inch angle iron about 20 inches long and .375 inch thick. At one end the webs are cut off and the end bent up at right angles for about three inches. The fast headstock is made from an old steering pillar ball race taken from a scrapped bicycle or purchased at some bicycle repair shop.

The headstock rests on a wooden block hollowed out to suit the height and diameter of the ball race. The entire headstock is clamped together by a piece of one-inch by .25-inch iron, bent and drilled to take a .375-inch bolt, as shown in the sketch. The tailstock is made up of a piece of .375 by nine-inch flat iron. This is drilled to suit the height of the headstock and is also bent over and tapped to take a .625-inch centre screw, which is fastened down by two three-inch screws.

The valve to be trued must have a slot cut in the stem, similar to that utilized for holding the screw driver when grinding, and should be placed up against the race as shown in the drawing and the back centre screwed up. The balls in the race are retained in position by the use of hard grease. A bitstock with a screw driver may be employed for rotating the valve, one person doing this work while another trues up the valve with a hand tool which may be made from an old file. A true surface may be cut by this method and the device will take valves of different diameters.

NEED OF PROPER LAMPS.

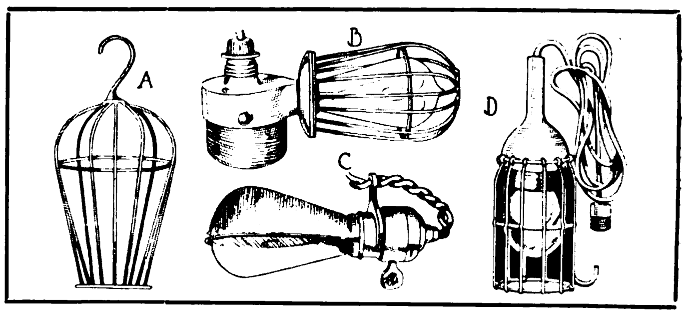
In changing over the stable to accommodate the commercial vehicle, or planning a garage, the lighting problem should be given proper consideration. It is an excellent plan to have extra sockets installed and in convenient places for more or less night work will be necessary where the driver cares for the machine. If the equipment is to include machinery the wiring plan of the lighting circuit should include drop lights with suitable shades.

In selecting the inspection lamps there is a wide variety from which to choose and in an accompanying illustration are shown several conventional designs. The hand or inspection lamp should be substantial, easily adjusted, and equipped with a hook for suspending the light when working about the chassis. The cord should be heavy and of a high grade material as it is subjected to hard service.

The reflector illustrated at C is very useful when working over the bench or lathe and it can be purchased for a few cents. The lamp shown at B presents practical features in that it is self-adhering, operating as it does on the magnetic principle. This enables the workman to utilize it where the ordinary member cannot be secured.

ACETYLENE TUBING.

With some types of generators more or less moisture forms in the tubing conveying the gas to the headlights and if the system is not provided with a trap for catching the fluid, considerable trouble will be experienced. Water in the piping is usually denoted by a flickering of the flame and a small blaze. Remove the tubing from time to time and blow out the water to prevent its creating trouble when the use of the lights is most desired.

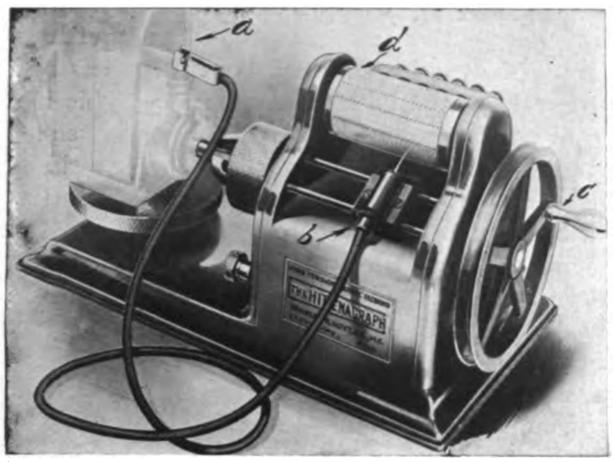


Suitable Inspection Lamps for the Garage: A, Type Utilized in Repair Shops; B, Magnalamp, an Electrical Device Self-Adhering to Metal by Means of Self-Contained Magnet; C, Magna Clip and Reflector Useful Over Work Bench; D, Inspection Member.

GARAGE AND SERVICE STATION EQUIPMENT.

IGNITION TESTING DEVICE.

An instrument designed for testing high-tension currents, magnetos, etc., has been brought out by Francis R. Hoyt, Cleveland, O. The name, Hitenagraph, is derived from its function, that of creating a graphic record of the secondary current.



The Hitenagraph, Designed for Testing High-Tension Currents, Magnetos, Etc.

The device is shown in an accompanying illustration testing a magneto for accuracy of performance. The Hitenagraph is simply constructed and its base is provided with a stand for mounting the magneto. The armature shaft of the latter is secured to the driving shaft of the testing device by a coupling similar in construction to the chuck of a drilling machine. The connection is so designed that the tapered shaft of the magneto may be held securely.

Rotating the driving wheel C revolves the armature of the magneto. The wheel is fitted with a handle, although its periphery has a V groove, permitting drive by a belt if desired. The drive is direct, there being no reduction. The chart drum revolves at an increased speed and the design is such that the spark index b which travels (through connection with a worm) longitudinally across the drum, is always diametrically adjacent, at the time the discharge should occur, to the ordinate on the chart itself on which the last produced spark registered. In this manner is shown, by the alignment of the sparks on the chart, the relative timing or synchronism of each cylinder, also the intensity of the spark by the area affected by it on the chemically prepared chart.

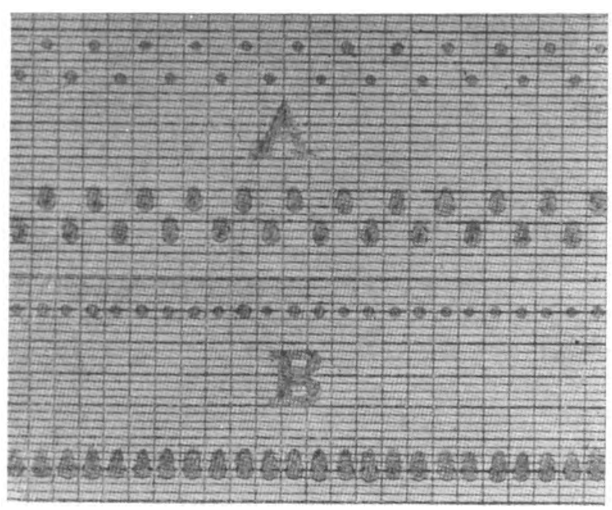
Two sections of the chart are reproduced herein, that marked A illustrating a typical case of lack of synchronism. The lines across the chart represent degrees of crankshaft rotation, or in other words, the chart as attached to the drum, is divided into 180 degrees and travels twice as fast as the magneto being tested. Each time the latter produces a spark, which is ordinarily twice a revolution, or 180 degrees apart, the chart makes a complete revolution and each succeeding spark should fall on the same line of the chart as the one preceding it. In the illustration at A the record shows that the magneto is five degrees out of time. The difference in the size of the spark at retard and advance, is also indicated. At B is presented a record of the same magneto after being repaired and adjusted.

The Hitenagraph may be utilized for testing a magneto without removing the latter from the car, a smaller model being manufactured especially for garage service. The larger or bench model is for use in factories and it is stated that it will test 20 machines an hour. This latter design is equipped with a variable speed device, and a tachometer giving graphically the revolutions a minute.

WOBBLING REAR WHEELS.

A large number of pleasure vehicles are converted into commercial cars and one of this type came into the garage with the rear wheel so loose on the axle that when it was jacked up it displayed an enormous amount of side play. The axle was fitted with a long, square key to drive the wheel. This was prevented from coming off by a .375-inch pin through the hub and shaft, which were both so badly worn that new members seemed almost necessary, but after some study the foreman devised the following plan:

The shaft was turned down .0625 inch for the length of the hub. The latter was removed from the wheel and bored out the same amount, leaving room for an .125-inch bushing which was constructed from steel tubing and brazed into the hub. The keyway was cut through the bushing to coincide with that in the hub, the one in the shaft deepened, and both widened to fit a new key. Then the wheel was assembled, placed on the axle, the pinhole drilled through the bushing, reamed, and a new pin driven in.



Chemically Prepared Chart Recording Lack of Synchronization at A and Proper Timing at B.

CORRESPONDENCE WITH THE READER.

Wattage of Lamps.

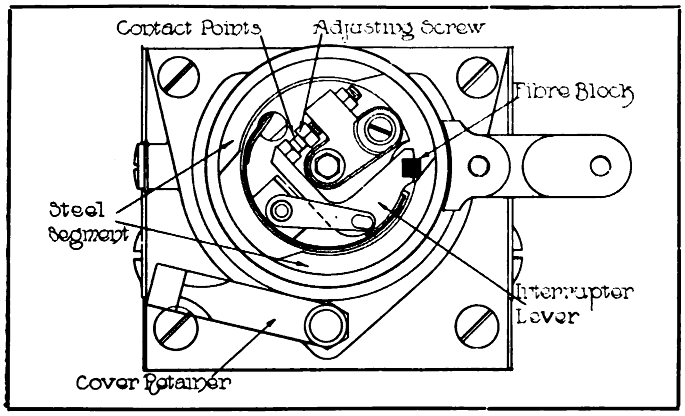
(30)—How do you ascertain the wattage of lamps; that is the number of watts consumed in an electric circuit, such as with lamps? CURIOUS.
Indianapolis, Ind., April 23.

To find the watts consumed in a given electrical circuit, such as with lamps, multiply the volts by the amperes.

Fitting Pistons to Cylinders.

(31)—I am contemplating fitting a new piston and rings to a motor that I am overhauling. Intend to make the piston and rings and would like to know how much clearance to allow between the piston and the walls of the cylinder. INFORMATION.
Albany, N. Y., April 26.

The usual clearance is about .001 inch, although there is a difference of opinion. Much depends upon the cooling efficiency, and as to whether the motor is air or water-cooled. Less than .001 inch has been used with success, but more is common practise. Before fitting a new piston it would be advisable to examine the cylinder to ascertain whether or not it is true. If not it should be rebored as fitting a new piston and rings to a worn cylinder—one that is out of true—will not warrant the expense and labor involved.



Illustrating Components of Breaker Box of Bosch Magneto.

Breaker Box of Magneto.

(32)—I have a small car I employ in my business, which has a high-tension magneto. It went out of commission the other day and I had to send for one of my trucks to be towed back to the garage. The workman said the breaker box was the cause of the trouble and that dirt had got into it. He advised covering the magneto, which I have had done. His explanation was rather meagre and I would be pleased to have the breaker box explained to me in simple language. MOTOR TRUCK READER.
Brooklyn, N. Y., April 12.

Dirt, grit or dust has no place in the breaker box of a magneto and the trouble was doubtless due to the grinding down of the fibre block which is employed in the circuit breaking mechanism.

In an accompanying illustration is presented a drawing of the breaker box of the Bosch magneto and the components are lettered to make clear their application. It will be seen that a fibre block is mounted on what is termed the interrupter lever, which also carries a spring for the purpose of keeping the platinum points normally in contact. The lever being pivotally mounted the points are separable when pressure is applied to the fibre block by the two segments.

The entire construction is attached to the armature shaft and revolves with it. The breaker box has two steel segments, which may be described as a ring with two pieces cut out and at exactly opposite points. When the lever is in such position that the fibre block is in the cut-out section the points are together, but when the shaft rotates further the fibre meets an obstruction and naturally is moved inward. This moves the interrupter lever, breaking contact between the platinum points and a contact is remade when the fibre reaches the cut-out section between the segments.

One platinum point is fixed, the other is adjustable and by loosening a lock nut the screw may be moved in or out as desired. The proper distance is about .5 mm and the points should be set with a Bosch wrench, which accompanies each magneto.

The housing containing the breaking mechanism is so mounted that it may be moved slightly, a lever arm being provided for this purpose. Advancing the spark, as it is termed, means that the housing is rotated a short distance so as to bring about an earlier breaking of the points. Retarding is the opposite movement.

The function of the breaking mechanism is to interrupt or break the primary circuit and this operation is practically the same as that of the timer or commutator employed with battery ignition and an induction coil. The primary circuit must be broken at just the proper instant; that is, when the piston is at the proper point and the cylinder filled with a compressed mixture.

The fitting of a cover to the magneto is to be recommended as the trouble shows that the instrument was exposed to road dust, etc.

Testing Out Leads.

(33)—What is the best method of testing out wires? In rewiring the motor of our truck I had considerable trouble as the wires are carried in a tube. I had to pull them all out and mark the ends before getting straightened out. DRIVER.
Fort Wayne, Ind., April 20.

There are several methods of locating a wire in a group as mentioned. One is to connect one end of an exposed lead to a battery and the second wire from the cells to an ammeter. The positive pole of the battery and that of the measuring instrument should be connected. By taking the free ends of the wires in the tube or elsewhere and touching one of them at a time to the free pole of the ammeter, the indicating hand will move when the proper wire is attached. This will close the circuit, denoting the cable.

A storage battery may also be used for testing. Attach one end of any of the group of wires to one pole of the battery and try each of the other ends on the remaining pole of the battery until a spark is noted. The same method may be employed with dry cells, but the spark will be much weaker and harder to distinguish. All that is necessary is to close a circuit.

ALL-METAL MOTOR TRUCK WHEELS.

The Development of Solid and Hollow Types and the Qualities Demonstrated from Continued Operation and Careful Experiment—Characteristics of the Best Known European and American Constructions Now in Use.

IN THE previous installment of this article the construction of wooden wheels for automobile vehicles was reviewed to considerable length, and it was shown that there are no standards of material or dimensions recognized, other than the standard established by the S. A. E. for rims. Not only this, that the wheels were often designed by axle makers, and are sometimes the result of figures compiled by a draftsman.

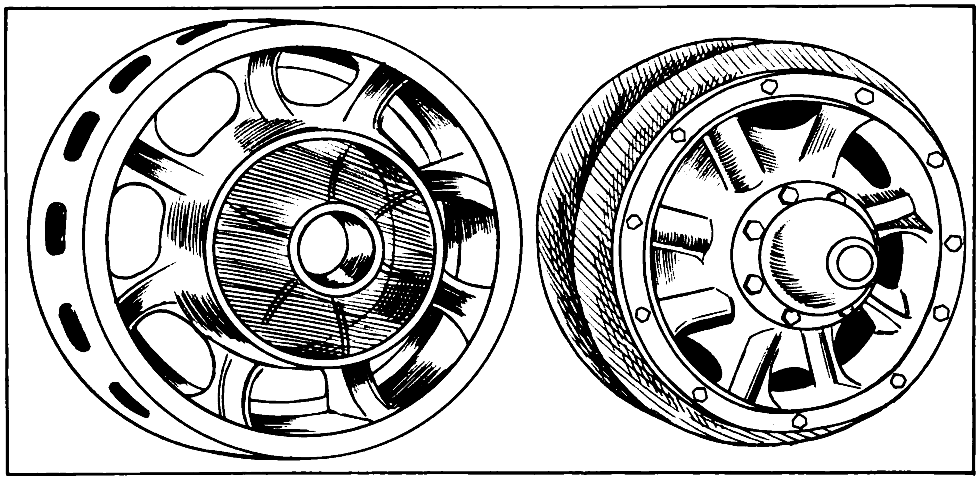
In this country, as has been emphasized, better qualities of wood are available than in Europe, though superior grades may be obtained on the Continent than in England. While it is true that the roads of Europe are much better when averaged than those of America, and this condition may offset the superiority of the American wooden wheel when endurance is analyzed, there is no doubt that the limitations of wood have been more carefully studied abroad.

It was the knowledge of the lack of strength of the wood wheel that prompted the construction of wire wheels, which were a development from the wire bicycle wheels, and though the first motor vehicles were often fitted with wire equipment, the wood wheel was later adopted very generally. In the creating of racing cars wire wheels came into favor, and the service resulting was such as to lead to the use of this construction by a number of leading makers. The car manufacturers of England have maintained that the uncertain strength of wood, the lighter weight and the longer endurance of wire wheels were all important factors in their very general choice of the latter. The use of wire wheels, however, was by no means confined to England, and a considerable number of builders of continental Europe have adopted them.

Wire wheels, however, have never been regarded with approval for service wagons, save for light vehicles, and with the utilization of heavy machines more attention was directed toward the development of metal constructions that would have greater strength and be lighter in weight. In fact weight has been a very potent factor in motor vehicle construction abroad because of the extremely high cost of fuel, and the desire to use the smallest engines that would afford sufficient power.

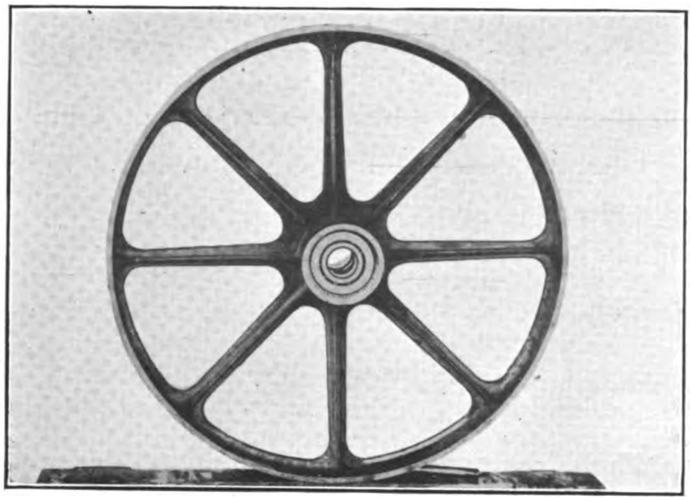
European engineers have gone more deeply into metal wheel building than have Americans and they have had the advantage of several years of experience. In England steel wheels have been used for service vehicles with a large measure of success, and in London some very large installations have this equipment throughout. The custom with most manufacturers is to give a purchaser the choice of either wooden or metal wheels. These all-metal wheels may be one of several forms or constructions. One is a solid iron or steel casting, another is a casting with hollow spokes, a third with hollow spokes and rims, a fourth is sheet steel stampings welded together, a fifth sheet steel stampings riveted together, and there may be other combinations.

Wheels of these types have been used in England for a considerable length of time. One of the faults developed by the first construction, especially those



The "Cored" Cast Steel Rear Wheel with the Brake Drum Integral, Made and Used by the A. O. Smith Company on Smith-Milwaukee Trucks.

with solid spokes, was that the spokes cracked close to the rim, probably due to the unequal expansion or casting strains, and possibly to the quality of the metal, and design was also another factor of material importance. The lack of satisfactory wood and the need of substantial construction impelled the makers to continue and today cast or stamped metal wheels are much used. In service they have been found to have greater rigidity than wood and to have from this fact a quality that appears to give greater tire service, as the wheels generally remain true and are not as likely to be "sprung" as wood, and there is a more uniform and regular movement of the tire upon the road surface. In England the custom is to bolt the brake drums to the metal wheels and there is less possibility, according to experience, of the wheels being affected by braking strains. While it is true there is



The Cast Steel Front Wheel for Delivery Wagons Made by the Sheldon Axle Company.

less elasticity than with wood, it is also true that the wheels are not affected by climatic or atmospheric changes, and the tendency of the wood members to twist and loosen is entirely eliminated.

Those who have observed metal wheels closely point out that with the solid spoke and solid rim type there is undoubted strength, but increased weight as compared with those having hollow spokes and rims, while it is maintained by some that the stamped metal wheels are less likely to crack from crystallization, and have the advantage of being hollow. It is maintained further, however, that the welded stampings are to be preferred to those assembled with rivets because there is no possibility of the members loosening the rivets from stresses and strains. The metal is not affected by heat or cold and can be protected by paint against all influences that would cause deterioration. The claim that the rigidity of the wheel causes the transmission of road shocks to the springs is met by the statement that with well lubricated bolts and shackles the springs should be equal to the absorption of any shock or stress.

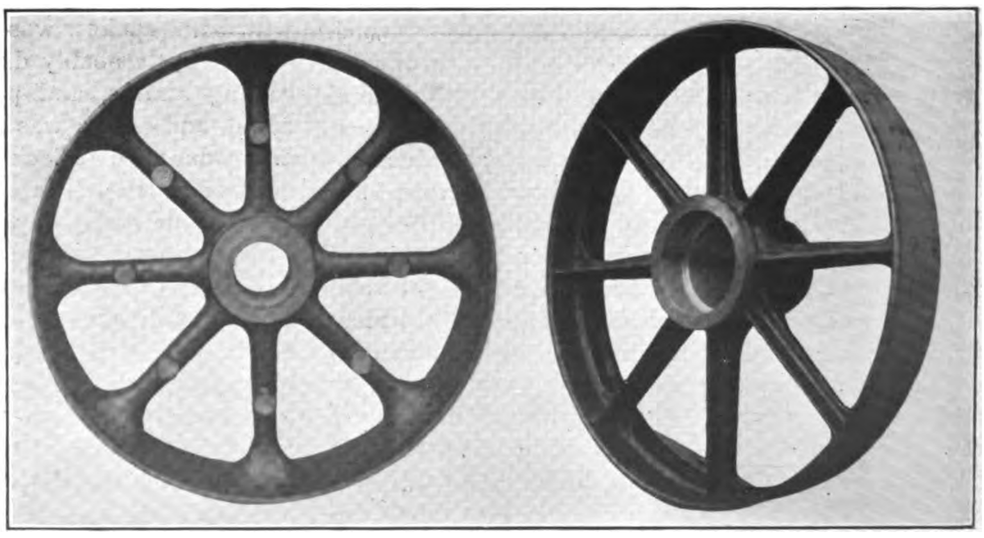
It is not possible to give data that will show the relative qualities of the different types of metal wheels used in England. So far as is known no tests have been made with a view of determining standards of dimensions.

In some instances the manufacturers of vehicles build the wheels they use, and others purchase of manufacturers who have specialized differing constructions. Admittedly there were failures of some of the wheels, but these were generally those used for experimental purposes, and in some instances because of the lack of metal.

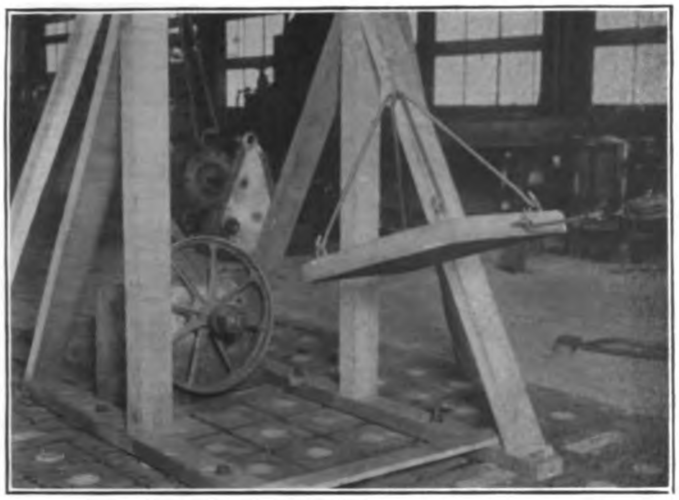
Another fault was the denting of rims from too soft material. One of the principal objections to the wheels was that when damaged it was believed necessary to replace the whole member, but this was before autogenous and electric welding had made possible a thorough repair, though there are those who maintain that breakage of the spokes close to the rim is a result of crystallization, and that after a failure from this cause a wheel ought not to be depended on.

The largest user of steel wheels in the world is the London General Omnibus Company, which has more than 2000 vehicles in service and expects to have this number increased to 5000, and one very important result, learned from exceedingly careful observation, is the increased endurance of tires. Tire cost is today one of the largest items of expense for motor vehicle operation, and any material saving will undoubtedly be welcomed, especially where the mileage is necessarily large. It is not practical, however, to measure results in London with what might be accomplished in America, for the London streets are, as a rule, decidedly superior to those of American cities, and there is a considerable difference between European and American tires. The service tire generally used in Europe has a larger cross section and contains more material, and consequently ought to wear longer than those that are manufactured in this country. However, gauged by the standard of European tires the steel wheel is maintained to be productive of greater mileage.

In this country there are five manufacturers of service vehicles that equip their machines with steel wheels. One is the White Company, which has used this form of equipment for perhaps two years. The wheels are designed by the company's engineers, and are cast in the company's foundry. These are a solid spoke type and are of different sizes for the several models of vehicles produced. The company is not willing to make public its manufacturing process. These wheels, which are standard construction, have given excellent satisfaction and are approved by the owners and operators of the machines. No data of comparative service or with regard to the endurance of the tires are found to be available.



Two Examples of the Desig n of the Cast Steel Wheels of the Sheldon Axle Company.



Sheldon Cast Steel Wheel Subjected to the Dynamic Pendulum Test Before Members of the S. A. E.

The Locomobile Company of America also equips its machines with wheels with solid spokes and rims, these being cast to designs furnished by the engineering department of the company by Isaac C. Johnson & Co., Spuyten Duyvil, N. Y., a concern noted for the high grade of its products. The statement is authorized by the company that its engineers conducted tests of both wood and steel wheels for from six to eight months to determine the relative merits, and from these experiments it was concluded that for a truck with a carrying capacity of five tons wood wheels were not reliable and did not have what was considered to be proper life. In addition to greater strength it was found practicable to reduce the weight in the steel wheels, a quality of material importance. Having reached this conclusion the company decided to build steel wheels and to use them with all vehicles produced.

The A. O. Smith Company, maker of the Smith-Milwaukee trucks, uses cast steel wheels on both its 3.5 and six-ton machines. These are a different construction than any made in this country or abroad, and are what is known to the maker as the "cored" type. The wheels are cast in the company's foundry from designs by its engineering department, and as they have been used for several years without failure or development of defect they are regarded as being in every way superior to any other equipment. In the casting the brake drums are made integral with the spokes and rims. The accompanying drawings show a rear wheel and the brake drum, and a rear wheel with the tires as it is seen on a truck, with the wheel cap bolted on. These wheels are constructed for use with a full floating rear axle, for the Smith-Milwaukee truck is driven by a shaft, worm and gear wheel.

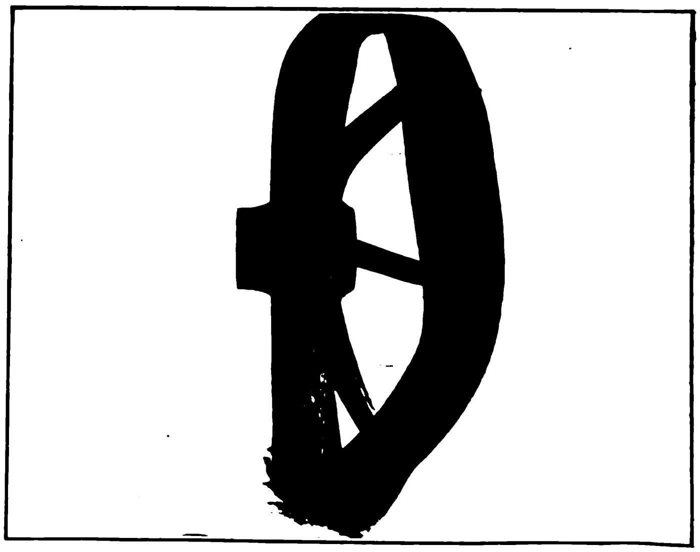
As will be noted from the drawing of the wheel without the tire, the hub and brake drum are supported by a series of eight spokes that are heavily webbed where they join the rim and the central section, and the spokes are really half-round channels in the web when seen from the inside, and have the usual half-round appearance from the outside. The semi-circular form of the spoke is continued to the rim, each being reinforced by a transverse web from the centre of the spoke to the rim, and between each spoke there is a web above the rim that really divides it longitudinally along the centre line of the spokes. The web uniting the spokes as they converge into the hub is wide and strong. Referring to the drawing without the tire, it will be seen that the spokes are each reinforced inside by a double web from the edges of the spoke channel to the rim. The form of the openings in the web of the wheel is well shown in this illustration. The rim of the wheel is cored at frequent intervals to secure lightness and to insure against casting strains. These wheels are said to average 20 pounds lighter for the front equipment for a 3.5-ton truck, and 50 pounds lighter for the rear wheel of the same vehicle, as compared with wood.

The castings are very smoothly made and are machined carefully, the rims being trued at the edges and the surfaces turned to take standard tire rims. The hubs and the brake drums are similarly machined, and when finished the wheels are balanced and have a satisfactory life and resiliency. The wheels are finished with paint or enamel and are not affected by climatic influences or changes of temperature.

Steel wheels are used by two other concerns, but these are made by others than the vehicle manufacturers.

The manufacture of steel wheels has been begun by the Sheldon Axle Company, Sharon, Penn., and this concern is now in a position to produce any sizes or types of equipment, or to make special work wherever the standard designs are not regarded as desirable. The Sheldon Axle Company is one of the largest makers of vehicle axles and springs in the world, and its manufacturing experience covers a long period. It has every facility for production, and the material used is selected with a complete knowledge of the requirements of service.

The company authorizes the statement that the construction of steel wheels was begun after careful investigation and exhaustive study of the causes of



Distortion of the Wheel by the Test, but the Casting Showed No Evidence of Fracture.

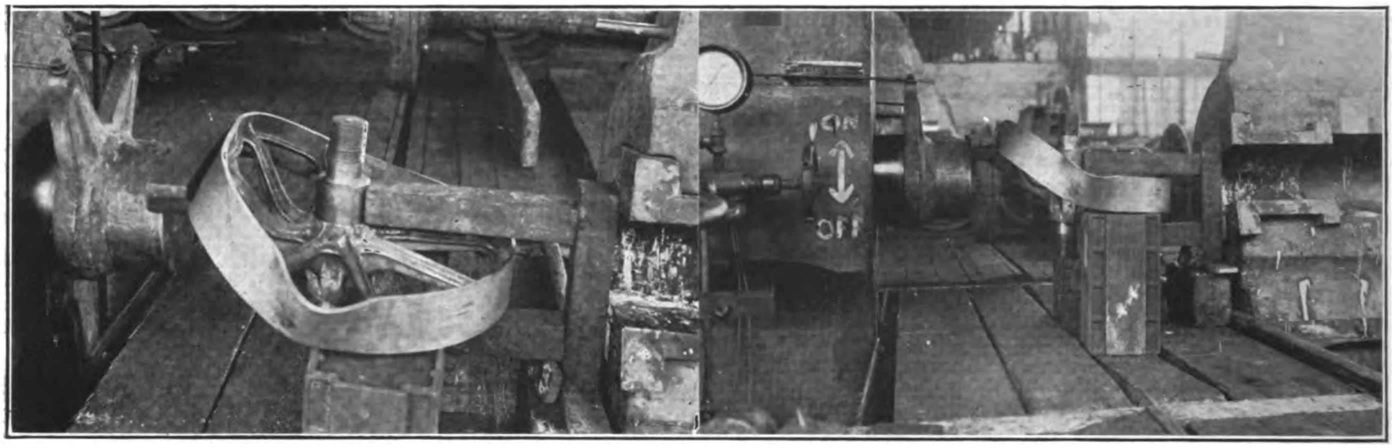
wood wheel failure, and believes that its products may be accepted as a positive solution of wheel fault. When the subject of all-metal wheels was given attention the engineering department made careful investigation and experiment, and designs were adopted that have been justified as meeting in every respect the exacting service of wagon and truck use.

The company claims that the steel wheels are superior to wood in three different respects—in stability for bad roads and rough handling, in increased strength and in economy through greater tire mileage. It is maintained that the European experience, of much trouble with wood wheels and very little with steel wheels, is conclusive proof that the steel wheel can be the better applied here than in Europe, for the roads are so much rougher and generally less improved. It is pointed out that with the large machines the wood wheel designs are constantly changed, the number and proportions of spokes being increased. In Europe some wheel builders are making laminated wood disc equipment. It is held that increasing the number of spokes is necessarily followed by the difficulty of securing them. The wheels will be subjected to extreme stresses under ordinary service, and wherever emergency arises, where it is necessary to lock the wheels with the brake, under full load or overload, continued use is eventually followed by deterioration. No conclusion has been reached as to whether or not the use of the brake is more severe on wheels than is road shock, but the change was made from wooden to steel wheels by the London General Omnibus Company because of the almost constant braking effort applied. While the omnibuses are driven under almost ideal road conditions, it is not unusual for brakes to be applied 2000 times in the course of a day. Some of the stops must be made under conditions that are exceedingly severe on the vehicles, the skidding on the paving making it necessary to protect windows, lamp posts and the like by erecting stanchions.

The combined lateral strains upon the wheel rim and the braking strain with the locked wheel causes the wooden wheel to yield and the joints to have more or less movement. The steel wheel is so efficiently ribbed that it is able to resist these stresses.

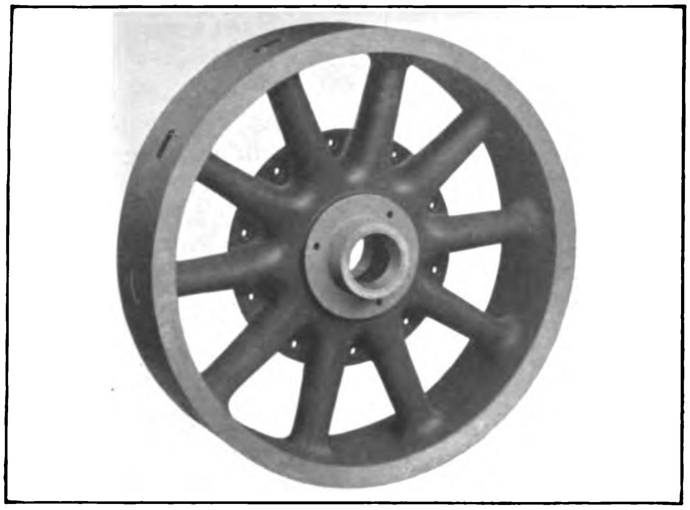
It is further maintained that the increased strength of steel as compared with wood is especially attractive to the engineer, as it gives him unbounded opportunities to materialize his deliberations in the most perfect manner known to the profession, and it is possible and practical for him to make estimates and calculations that can be thoroughly relied upon.

This may be illustrated by taking for example a steel wheel having a diameter of 40 inches, with spokes having a star cross section four inches from the centre of the hub, the section of which would be 4.75 by 2.5 inches and .4375 inch thick. The larger section, parallel to the axis of the axle, may be compared with a wood wheel hub having a three-inch square spoke. Assuming the ultimate strength of the steel at 75,000 pounds a square inch and the wood 10,000 pounds a square inch, the steel wheel would allow a pressure of 7200 pounds on the rim and the wood wheel but 2800 pounds. These figures are taken from a very successful steel wheel application weighing less than wood wheels. Obviously, the wood wheel would necessarily have more than twice the number of spokes to have the same strength from these same factors alone. As the whole load is sustained by two or three spokes when the machine is skidding, the economic disposition of the material to react on the side strains can be the better appreciated.



At Left, the Sheldon Cast Steel Wheel After Undergoing a Hydraulic Test of 25 Tons; at the Right, the Manner in Which the Pressure Was Applied.

Comparing the section moduli at the juncture of the spoke to the hub on steel wheels with wood wheels, there is no doubt of the superiority of the former with reference to strength. It is held that the star sections appear so light to American engineers that they have deemed it wise in many instances, for appearance only, to resort to other sections, such as the U or round, although the star appears to be the most economic, considering the combined driving, braking and skidding strains. The tendency of engineering practise is toward a high grade steel casting, having, for instance, an ultimate strength of approximately 75,000 pounds to the square inch, an elastic limit of 35,000 pounds to the square inch, a reduction of 40 per cent. and an elongation of 30 per cent. It is believed that



The Timken-Detroit Malleable Iron Hollow Spoke and Rim Rear Motor Truck Wheel.

these figures will be a good standard for a considerable period. These figures apply only to steel, and not to malleable iron and semi-steel constructions.

It is claimed for steel castings of the above physical properties that they can be easily forged when properly annealed, and in the event of accident a wheel can be straightened without fear of fracture, and even welded if this be necessary.

Regarding the economy of tires, which is maintained to be a very important factor in favor of steel wheels, it is claimed that there is a distinct saving with steel equipment, and that some of the largest tire manufacturers guarantee as much as 30 to 40 per cent. longer life with such wheels. The London General Omnibus Company uses 34 by four-inch single solid tires forward and 40 by four-inch dual solid tires rear, and it is claimed that the average for a set of tires is 25,000 miles, and that in one exceptional case a pair of front tires was driven approximately 50,000 miles. The omnibus chassis weighs about 6300 pounds, and it is practically built for a three-ton load, having accommodation for 16 passengers inside and 18 on the roof deck. These chassis are geared seven to one on the high speed and with the 40-inch traction wheels a speed of 30 miles can be attained, which is admitted to be about twice as fast as these machines should be driven. The guarantee of the tires would be void immediately if such excessive speed were made on solid tires in America. In addition to this is the fact that the brake is applied an average of about 2000 times daily.

The first steel wheels produced by the Sheldon Axle Company were for wagons of one and two tons capacity, the forward wheel for the ton wagon to be equipped with 34 by 3.5-inch tires. The weight of the wheel is 99 pounds. Some of these wheels were tested with a dynamic pendulum at the works of the Treadwell Engineering Company, Easton, Penn., Jan. 15, before a number of members of the Society of Automobile Engineers, for Arthur E. Laycock, chief engineer of the Sheldon Axle Company. The wheels are made of a very high grade of electric furnace steel. The result of the tests for a two-ton front wheel is given in the following:

Blow		Permanent Deflection	Total Deflection	Energy of Blow in Foot Pounds
1	36 inches	0	0	216
2	42 inches	0	0	294
3	48 inches	0.046675 inches	0.046675 inches	384
4	54 inches	0.078125 inches	0.078125 inches	485
5	60 inches	0.109375 inches	0.234375 inches	600
6	72 inches	0.203125 inches	0.0375 inches	865
7	108 inches	0.75 inches	1.1875 inches	1940
8	120 inches	0.9375 inches	2.125 inches	2400
9	144 inches	1.1875 inches	3.3121 inches	3640
10	144 inches	1. inches	4.3125 inches	2460

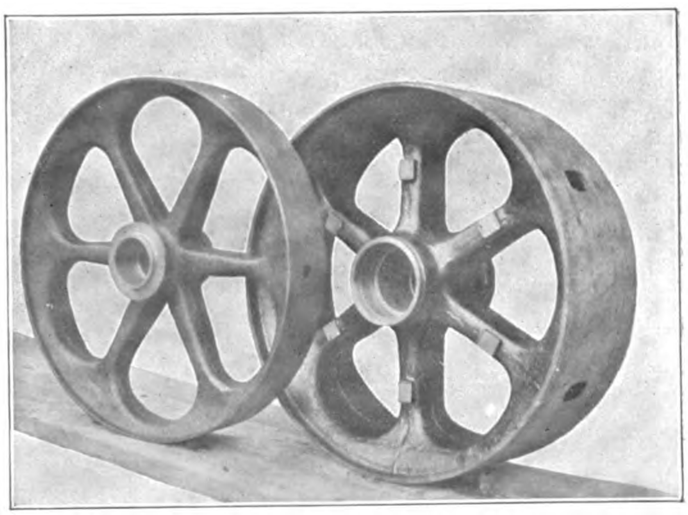
The test to which the wheel was subjected was a lateral impact at its rim with a 480-pound pendulum.

When the pendulum test was completed the bent wheel was placed in a hydraulic press and a radial load of 25 tons was applied to that portion of the wheel rim that was bent. The accompanying illustrations show the wheel before and after each test.

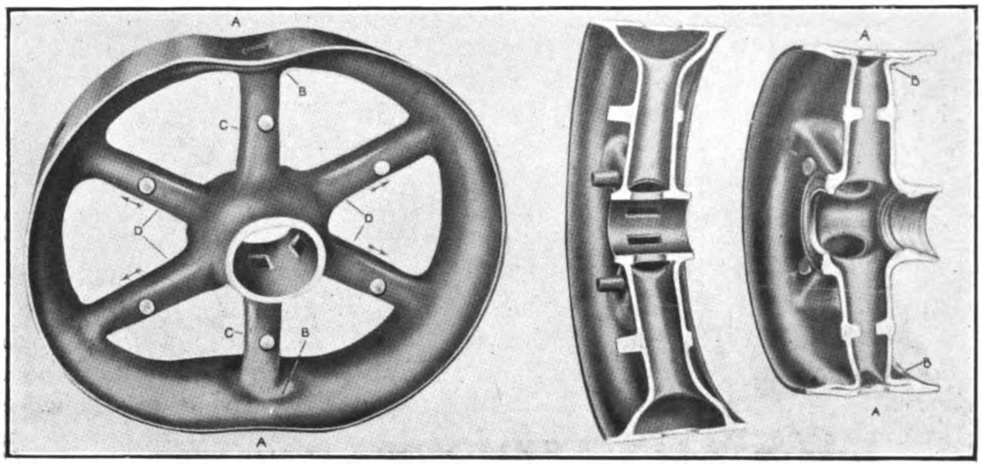
Regarding the qualities claimed for the wheels, other than those that have been stated, it is claimed that they will not warp, swell or shrink in any climate, and that the very thin metal rim and perfectly cylindrical form is an important factor in the radiation of heat. As the wheels are machined all over they are certain to be true in every respect. They will not collapse under any stress, and even should they be bent they can be restored to the original form. Because of the lighter wheels it is maintained that the vehicles can be accelerated more easily and quickly, which means fuel economy, especially when many stops are to be made. Being very resilient, the wheels will yield and will not be damaged from ordinary shocks.

From the viewpoint of the manufacturer it is held that there is an economy in a wheel that has but one part as against the 18 of a wooden wheel, or four against the 72 of a chassis, considering the bolts, nuts, flanges, hubs, rims, etc. This elimination of parts make upkeep and maintenance an easier proposition. The rim of the wheel takes the band of the tire, for the wheels are finished to the S. A. E. standard.

The Sheldon wheels have been designed with special reference to the use of axle bearings, for the fitments differ with the manufacturers, and these wheels can be fitted with the Standard Roller Bearing Company's taper roller bearings, the Bower straight roller



Forward and Rear Heavy Cast Steel Truck Wheel, Made by the George Fischer Electric Steel Works, Schaffhausen, Switzerland.



Result of Test of Fischer Wheel by Dropping a Ton Weight on It; At Left, the Spokes Telescoped into the Rim; at Centre, a Section of Wheel Showing Construction, and at Right, a Section of the Tested Wheel, the Cored Rim Being Flattened.

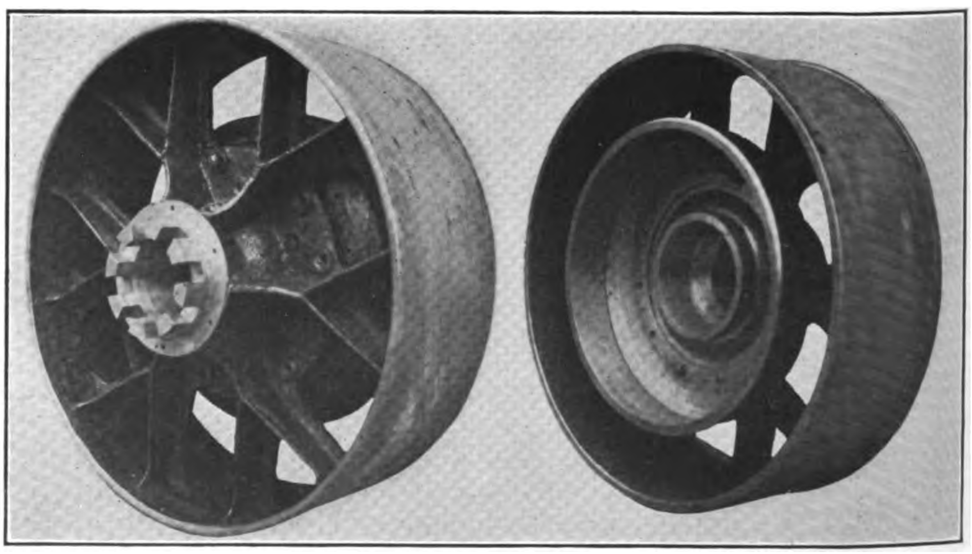
bearings, the New Departure double row annular ball bearings, all of these three makes being interchangeable in the hubs. It is also possible to use any standard double or single row annular bearing by the addition of a spacer.

The Timken-Detroit Axle Company has begun the manufacture of malleable iron wheels for service wagons, and an example of the finished product is shown in an accompanying illustration. There are no engineering data available as to the strength and endurance of these wheels as compared with wood, although the company has developed these wheels after a series of tests that has, in the minds of its engineers, thoroughly established their value. No information is given as to the manufacturing process. The company authorizes the statement that, in the opinion of its engineers, eventually the metal wheel will be generally, if not universally, adopted for service vehicle equipment. Some of the qualities which will lead to this preference are, according to the company, that they are, or soon will be, no more expensive, that they are no greater, if not less, in weight, and that they are very much stronger and neater in appearance.

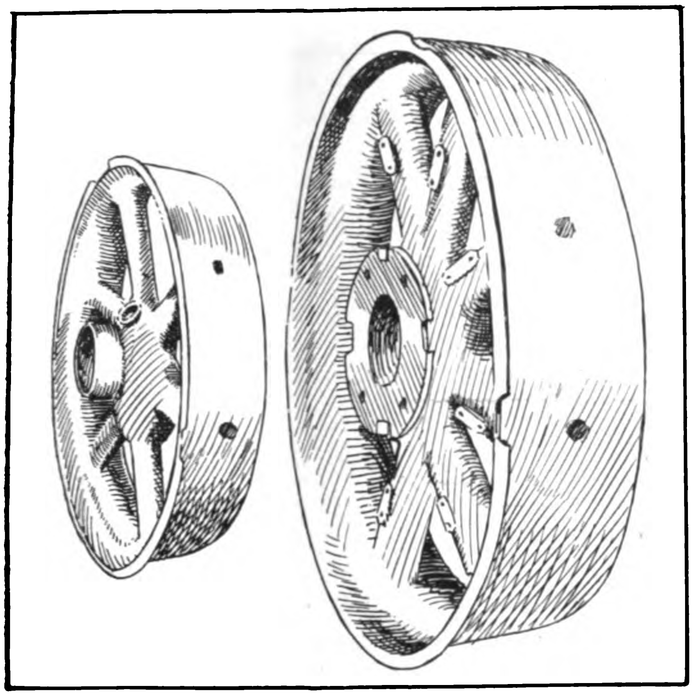
From the viewpoint of the American engineer the simplest manner to make anything of metal is to cast it, and cast iron wheels would not meet the requirements, not having the strength to resist the strains, and the metal has not the ductility that will justify its use. The Timken company's belief is that it is difficult to cast steel so that it will be homogenous and uniform throughout, and for this reason malleable iron is selected as the material that will give the greatest satisfaction, assuming, of course, that the design of the wheel is correct. It is characteristic of malleable iron that it is strongest on the surface or "skin," and the Timken-Detroit wheel is designed with the greatest surface that is possible to have, which is acplished by casting the entire wheel, hub, spokes and rim, hollow. Where the spoke joins the hub and the rim the surface of the casting is curved on an arc, which has a radius sufficient to prevent shrink cracks.

The accompanying illustration of a Timken rear wheel shows that the design appears large, the rim, spokes and hub having a large surface area, and the spokes flare at the juncture with the rim. It will be noted that the wheel is cored from the hub through the spokes to the rim, and that the hub seems to have unusual size. The flange to which the brake drum is bolted is cast integral with the hub, and this forms a web between the spokes that materially strengthens the construction. The wheel is finished by careful machining and is turned true to its axis. The hub cap is bolted on. In actual size the wheel is about the same as though it were made of wood. The wheel is a single piece and this simplifies the attention that is necessary. It may be painted and is smooth and neat. The rim being made to standard size, any tire may be fitted. The statement is made that the Timken-Detroit wheel will endure pressure from different directions much better than a wooden wheel, and under numerous comparative tests it has been proven to be sufficient for any character of truck service. The wheels are made in different sizes. Relative to manufacturing, it is stated that it is a comparatively simple process to make the malleable iron casting, to machine it to truth, and to fit the cups for the Timken bearings.

A wheel that has recently received considerable attention from American automobile engineers is the



Rear Truck Wheels of the "Y" Spoke Type, with Brake Drum Bolted to the Webs, One of the Older Fischer Constructions.



Forward and Rear Sheffield Cast Steel Wheels with Hollow Spokes and Rims, Without Tires.

Fischer steel equipment, which is a product of the George Fischer Electric Steel Works, Schaffhausen, Switzerland, for which Peter A. Frasse & Co., 417-421 Canal street, New York City, is American agent. This company is probably the pioneer in the production of steel wheels in Europe and it is claimed that it is the largest manufacturer of this product in the world. The Fischer steel wheels are used very generally in England, many of the truck makers having adopted this equipment, and among the users is the London General Omnibus Company, to which reference has been previously made.

These wheels are made in different sizes and for differing types of vehicles. In the development various forms were experimented, among these being the solid type with the plain cross section spoke and the "Y" section, but the designs that have been adopted are those with the hollow spoke and rim for four to six-ton trucks, and the solid rim and hollow spokes for the lighter vehicles. The manufacturing process has been carefully developed. The material is a comparatively low carbon steel, it being about .02 per cent., and as it is smelted in electric furnaces, where there is absolutely definite control of the temperature, the metal is of exceptional purity.

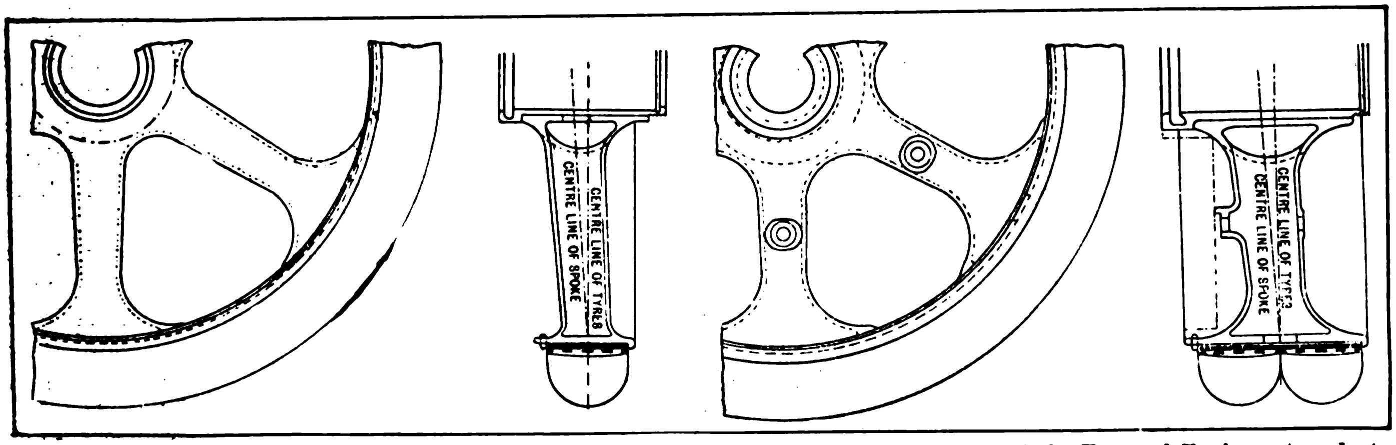
In the casting great care is taken to have the thickness of the walls of the wheel uniform, and it is approximately .4 inch, but this does not apply to the bosses and special parts of the hubs. This construction gives a very light and strong wheel, and it is smooth and pleasing in appearance. The extreme ductility of the metal makes for great strength and in the machining of the rim a spiral chip has been made 21 feet long, the actual length being very much in excess of this. The ordinary steel casting chip is comparatively small.

The strength of the wheels has been tested in different ways, but one of the most interesting was the dropping of a weight weighing a ton a height of 24 feet on a rear wheel of the hollow spoke and rim type. Four times the weight was dropped, and the result was that the outer web of the hollow rim was compressed to the inner web, and the effect was to flatten the wheel at top and bottom, bringing the walls of the rim closely in contact. But the hub and the remainder of the wheel was not changed.

The wheels made for the London General Omnibus Company are the hollow spoke and rim type, and this form is specified for the military trucks of the French, German and Italian armies. Other users are the London General Transportation Company, the Daimler Company, Leyland Motors Company, Halleys, Albion, Commer trucks, Dennis Bros., and Maudsley. The wheels built for the London General Omnibus Company are 36 inches diameter and these are fitted with four-inch single solid tires forward and four-inch dual solid tires rear. The front wheels weigh 112 pounds and the rear wheels 216 pounds. The tire equipment is not demountable, the tires being forced onto the rims under heavy pressure.

A number of truck manufacturers of America have ordered Fischer wheels for experimental purposes, and some of these are now in use, in many instances the machines used for experimental purposes being equipped with them. These wheels are of the hollow spoke and rim type.

A patent is held by a Boston company, which made

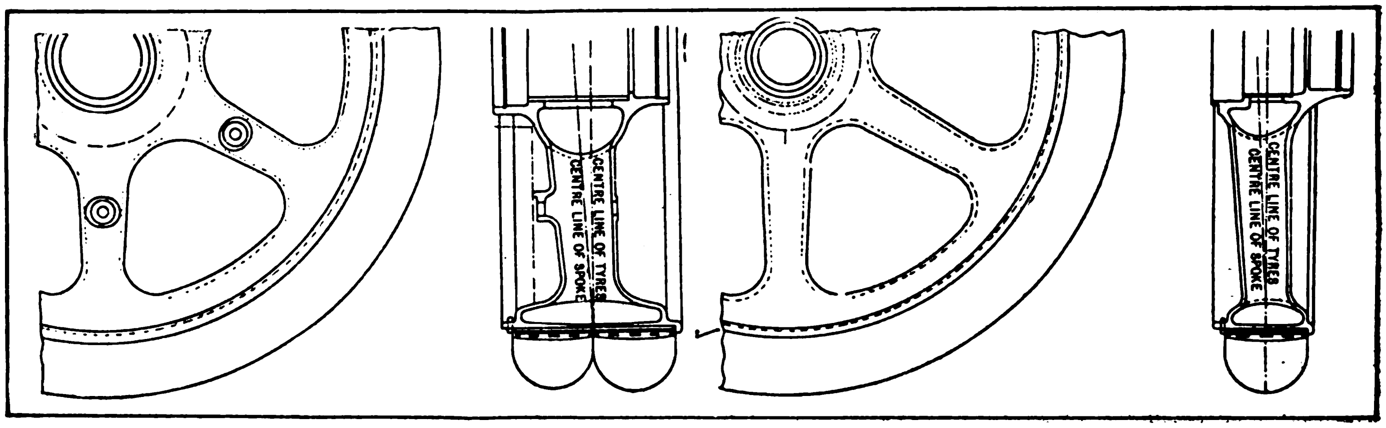


Sheffield Cast Steel Wheel, with Solid Spokes and Rim: At Left, the Side and Cross Section of the Forward Equipment, and at Right the Rear, with Dual Tire Installed.

exhibition at the 1912 service wagon show in that city, for a cast steel wheel in which the spokes are hollow and the brake drums are integral with the casting. This construction is considered by the patentee to be more advantageous than with the brake drum separate. The assembly is stated to be approximately 250 pounds lighter in a rear wheel of 36 inches diameter. A test of the metal used was made at the laboratory of the United States arsenal at Watertown, Mass., and it was found to have great strength and ductility. One test made was to drop a wheel without a tire about 15 feet onto a solid granite ledge, and after 18 tests of this kind the only damage found were dents in the rim.

Steel wheels are made commercially in England by the Sheffield Steel Castings Co., Ltd., Sheffield, and are made in two designs, the one with the spokes and rims hollow, and the other with hollow spokes and solid rims. As compared with wheels cast solid with cross section spokes, it is claimed that these wheels are considerably lighter though stronger, are more durable, are not so likely to be affected by severe vibration, they are more easily cleaned, have more resiliency and are in every way sightly. The success of the wheels in service is attributed to the special steel used and the processes of manufacture. In casting the metal is heated in an electric furnace and is subjected to special treatment before it is poured into the molds. With the hollow rim types the outer periphery of the wheel is supported by webs. After casting the wheel is machined, and this work is done to .001 inch. While the company produces these to its own designs it also furnishes work to any specification.

The accompanying sectional drawings will illustrate the construction of the Sheffield steel wheels. Both types are shown. One of these shows the side and cross section of the hollow rim form, for both front and rear wheels, and another shows the side and cross sections for front and rear wheels of the solid rim pattern. In all cases the drawings illustrate tires on the wheels, this giving a better idea of the design. A front and rear wheel of the hollow rim type is also illustrated. The wheels have been sold in the market for upwards of two years and have been supplied to a number of British vehicle manufacturers.



Sheffield Cast Steel Wheel with Hollow Spokes and Rim: At Left, the Side and Cross Section of the Rear Member, and at the Right the Rear Equipment.

INCREASES CAPITAL STOCK.

Motor Foundry Company to Enlarge Capacity for Producing Engine Castings.

Stockholders of the Motor Foundry Company, Detroit, at the annual meeting, gave approval to the plan for increasing the company's capital from $35,000 to $100,000 to provide funds for extensions of the plant necessitated by enlarged business. The additional capital has been fully paid in and work has begun on the erection of new buildings adjoining the present plant, which covers 2.5 acres on Hart avenue. The company employs 265 men and has a melting capacity of 40 to 50 tons of iron a day. Completion of the additions will increase the capacity to 80 tons a day.

The plant is one of the largest gray iron foundries in the country producing exclusively castings for gasoline motors. The officers are: President and general manager, J. H. James; vice president, E. A. Nelson; secretary and treasurer, L. H. Green. The active management of the company is in the hands of Mr. James and Mr. Green, both young men of wide experience as foundrymen in iron, steel and malleable iron castings.

TO LOCATE IN NASHVILLE.

Evans Motor Car Company to Manufacture Commercial Vehicles in New Plant.

The Evans Motor Car Company of Nashville has been chartered at Nashville, Tenn., with capital stock of $50,000 to manufacture commercial motor vehicles and the Evans gas engine. The incorporators are: Everett Philpot, George R. Anthony, Howell Brandon, Clarence Woodcock, A. P. Foster and R. H. Evans.

The concern will take over the business of the Automobile Manufacturing & Engineering Company of Detroit, in which Mr. Evans is interested. It is the intention of the company to locate the factory five miles from Nashville on the Gallatin pike. It is planned to manufacture 500 cars the first year and later to increase the capital stock to $200,000. The plant will eventually employ 600 to 1000 men.

LEGISLATION--DEFEATED AND PENDING.

THE owners of motor service wagons in Rhode Island were successful in their opposition to the bill, pending in the General Assembly, that purposed to tax all machines used for business purposes $20 for one ton capacity or less, and $10 for each additional ton capacity or fraction thereof. The bill was introduced into the senate at the request of the board of public roads, and was passed without a public hearing, at least such hearing as was known to the public by advertisement. It went to the house and there was referred to the committee on the judiciary, and without an advertised hearing it was favorably reported to the house for concurrent action.

When the bill was before the committee, just before the house was called to order, request was made the committee to give a hearing, and the members consented to hear those opposed to the bill when a petition was presented signed by some of the large manufacturing interests of the state. Those particularly active in opposing the bill were instrumental in calling a meeting of the truck owners of Rhode Island, which was held in the Providence salesrooms of the Packard Motor Car Company, and was presided over by John D. Turner, superintendent for the Seaconnet Coal Company.

At this meeting, which was largely attended, explanation was made of the situation, and the necessity of immediate and united action urged. The statement was made that the motor vehicles were taxed to the full valuation by the city, that wherever changes had been made for the purpose of housing the machines the value of the property had been materially increased, and further, the greater part of the use of the vehicles was on the streets of the cities and not on the state roads. It was maintained that there would be one of two results from the taxation: That the use of motor vehicles would be given over by some, and there would be a retardation of the utility of such means of transportation, or the people would be required to eventually pay the increased cost.

At the meeting were representatives of large manufacturing interests, coal companies, ice companies, breweries, truckmen, and those having large volume of haulage, and it was stated that it was the intention to have a permanent organization which would systematically promote every interest having to do with vehicular transportation.

At the request of those present, William W. Scott of MOTOR TRUCK, who is actively concerned in state legislation, explained that the present registration fee of $2 a service wagon was established when the bill was before the legislative committee through representations made to the committee, and it was then the unanimous opinion that a vehicle used for business purposes was not destructive of the highways and that they were fully taxed. That committee had not hesitated to place what was then, and is now, as heavy a tax on pleasure cars as it was believed the owners would pay, but it did decide that to tax a business vehicle was unreasonable and unjust. He also showed that the cities of the state pay more than 85 per cent. of the state tax, and consequently that proportion of the state expenditure for highways and their maintenance, although not an inch of state road is in the cities, and that taxation of the motor trucks, practically all owned and used in the cities, was an endeavor to benefit the towns at the expense of the cities.

The meeting appointed a committee to appear before the legislative committee, and a committee to secure signatures to an organization agreement. The committee on legislative action was heard the following day by the committee, its endeavors being supplemented by a number of attorneys representing the American Locomotive Company and other interests. The committee finally stated that as the measure came from the state board of public roads the remonstrants should appear before that body. The following day the committee and the lawyers appeared before the state board, which admitted the bill was solely intended to produce revenue, and reiterated the remonstrances. The result was that the bill was withheld by the committee and was not reported. One reason for this was the fact that there is to be a special election in the state early in June to authorize an issue of bonds for the improvement of the state highways, and there is no doubt that the influence of the owners of the 1000 or more motor vehicles in the state could be exerted to defeat the proposal to issue bonds, especially when the apathy of people in special elections is realized.

The failure to report the bill ended the attempt to tax motor wagons in Rhode Island, for the year of 1913, at least. Meantime the owners of such vehicles are proceeding with the organization and will be prepared for any further attempts of the kind.

In Massachusetts the bill indorsed by the state highway commission, which proposed to tax motor wagons $5 a ton capacity or fraction thereof, which was before the committee on roads and bridges, and had been recommended as a substitute for a bill that had been agreed upon by the highway commission and representatives of motor wagon owners which comprehended a tax of $5 for the first ton and $2.50 for each additional ton or fraction thereof, is now pending before that committee, having been recommitted to it at the request of hundreds of interests as represented by petition. The bill was proposed by the state highway commission. It is avowedly a measure for the purpose of increasing the revenue that the commission can expend on highways, and as there are now approximately 5000 service vehicles in the state, and this number is rapidly increasing, there is little doubt that the bill would yield at least $100,000 the first year. The bill also proposes to limit the weight of machines to 12 tons when loaded.

A meeting of truck owners, the Boston Commercial Motor Vehicle Association and differing organiza-

tions having direct interests, as well as labor federations, was held in Boston April 24, at which a systematic campaign was begun to defeat the bill, if possible. It was stated that the state highway commission had not kept faith with those with whom a compromise bill was agreed upon, and for that reason the associations which had consented to the compromise did not feel bound to support the measure in any manner. Committees were appointed to carry on the campaigning, and it was agreed to direct endeavor toward all members of the legislature, as well as the committee.

The legal phase of the remonstrance was left with James B. Sullivan, Jr., counsel for the Boston Commercial Motor Vehicle Association, he to make the plans for the hearing to be given the remonstrants by the committee May 6, and it was decided to have the large business interests represented so far as possible by owners and users of machines. Acting in concert with the owners is the Automobile Legal Association, the Automobile Owners' Association, the Electric Motor Car Club of Boston, the Electric Vehicle Association of America, and the several motor vehicle manufacturing companies of Massachusetts. Besides these a number of the large makers of machines located outside of the state, but doing business in it, and representing many thousands of dollars invested in branches and service stations, united with the committee of owners.

It was pointed out to this meeting that there were many concerns in Massachusetts doing business in other states, and concerns in other states doing business in Massachusetts. The outside enterprises were taxed in their own states, and to heavily tax them for the use of vehicles in Massachusetts would undoubtedly result in the enactment of retaliatory legislation that would still further increase the burden upon the owners of motor service wagons.

The committee on May 6 listened to the arguments made in behalf of the remonstrants to the bill and received a petition of more than 1500 names from men whose employment might be seriously affected by the enactment of the proposed bill. The bill was favored by a single individual, who said that he appeared as a private citizen, and his argument was that motor trucks should be made to pay for the maintenance of highways used by them. Incidentally, it should be stated that the members of the committee had been taken over some of the roads of the state, assumedly under the direction of the state highway commission, to get a knowledge of the conditions that were urged to justify the bill.

It was developed at the hearing that the state highway commission has jurisdiction over but seven per cent. of the roads of the commonwealth, and it was maintained that there was no statement showing the wear resulting from horse wagon traffic, which is many times the volume of motor wagons. Of the speakers was Lewis R. Speare, former president of the American Automobile Association, the owner of six trucks, who pointed out that if there was to be a tax for the use of the highways, this tax should be paid by all users. Treasurer and Chief Counsel W. A. Thibodeau of the Automobile Legal Association maintained that the proposed tax was unjust and unconstitutional; that the Illinois supreme court had declared a similar law unconstitutional, and that in New Jersey, where the question of constitutionality was raised, the supreme court had implied that to impose a tax greater than was necessary to maintain a department for motor vehicle registration was not constitutional. Other aspects were touched upon by different speakers.

The purpose of the remonstrants is to leave nothing undone that will in any way bring about the withholding of the bill, and from the large interests protesting against its enactment and with the fact that but one individual besides the state highway commission favored it, it is not improbable that the measure will not be reported favorably. If it is reported with a recommendation of passage there will be a contest on the floor of the house.

In New York the Automobile Dealers' Association conducted a campaign against the passage of the bills pending before the legislature of that state through personal effort and by letter to differing interests and to the members of the legislature, and in this work directed its endeavors along lines that were determined by practically every industrial, trade or promotive organization in the state.

The National Association of Automobile Manufacturers, through its department of publicity, has directed the attention of every industrial and trade organization in Massachusetts, Rhode Island, New York and Pennsylvania to the pendency of the bills and the probable result from enactment, and has supplied much valuable information relative to legislators, that they might be reached by those who desired to make protest against the measures. The commercial vehicle committee of the association closely observed the progress of the legislation and informed all interested relative to such influences as are wise to counteract.

In New York the legislature before adjournment amended the bill relating to automobile registration, but there was no change made in the fee charged for registering service vehicles. In Pennsylvania it is believed very probable that the proposed bill will be enacted before the session is adjourned.

In Indianapolis the Hoosier Motor Club has obtained a temporary injunction against the city which prohibits the enforcement of an ordinance levying a tax on automobile vehicles until the final hearing of a suit instituted by the club to determine the validity of the ordinance. The Indiana legislature recently passed a law providing for a graded license tax on automobile vehicles and that the proceeds of the tax shall be used on the roads of the state. The ordinance does not provide for the use of the proceeds of the tax on the streets. It is maintained by the club that one tax is sufficient, and the objection is chiefly on the ground of double taxation.

NEW YORK CITY'S PROPOSED WHEEL TAX.

THERE is now pending before the board of aldermen of New York City an ordinance introduced by President McAneny of the borough of Manhattan, which, if passed, will impose a wheel tax upon every vehicle owned in New York or which is driven upon the streets of that city. This ordinance proposes to regulate the width of tires, wheel loads and width of vehicles by the issuance of licenses by the bureau of license, this bureau being authorized to issue licenses and permits, to collect fees and to employ the necessary clerks and inspectors and weighing stations. Under the ordinance the licenses shall be issued annually. It is provided that any vehicle carrying or intended to carry a total gross load of 6000 pounds or less upon any wheel shall be charged the following annual license fees, per vehicle, based on the load in pounds per inch width of tires: 750 pounds or less, $1; 751 to 800 pounds, $3; 801 to 850 pounds, $6; 851 to 900 pounds, $12; 901 to 950 pounds, $25; 951 but not to exceed 1000 pounds, $50.

In addition to the above fees further fees shall be charged for loads greater than 6000 pounds, but not to exceed 10,000 pounds, upon any wheel, as follows: 6001 to 6500, $75; 6501 to 7000, $110; 7001 to 7500, $150; 7501 to 8000, $200; 8001 to 8500, $300; 8501 to 9000, $500; 9001 to 9500, $750; 9500 and not to exceed 10,000, $1000. For loads greater than 10,000 pounds per wheel, license fees shall be charged for each vehicle at the additional rate of $500 for each 1000 pounds increase in weight, or portion thereof per wheel, provided, however, that no greater weight than 1000 pounds per inch width of wheel shall in any case be permitted except under a separate clause, special permits for single trips can be issued at fees of not less than 10 per cent. of the annual fee, and no permit fee shall be less than $25, where the load is more than 6000 pounds or more on any wheel. Vehicles more than 78 inches in width shall be charged the following license fees for each inch in excess of that width: 78 to 84 inches, $5 an inch; 84 to 90 inches, $10 an inch; 90 to 96 inches, $15 an inch; 96 to 102 inches, $20 an inch; 102 to 114 inches, maximum width permitted, $25 an inch. It is provided that any fraction of an inch shall be regarded as a full inch, and that no load, rigging, harness or other equipment shall be permitted to extend beyond the width of the vehicle. Special permits for excess width for a single trip may be granted by the payment of a fee of not less than $10. The ordinance provides that plates in duplicate stating the weight of the vehicle empty and the maximum capacity loaded per inch of tire and per most heavily loaded wheel and width overall shall be furnished by the city upon payment of the license fee, and shall be permanently attached in a conspicuous place on each side of the vehicle. The ordinance also provides for weighing stations in such numbers and at such places as may be determined by the board of estimate and apportionment upon recommendation of the chief of the bureau of licenses, and all vehicles shall be weighed at such weighing stations as often as may be required by an authorized representative of the bureau of licenses. Violations of the ordinance may result in revocation of license, the owner may be deemed guilty of a misdemeanor, and upon conviction be fined not less than $100 nor more than $500, and in default of payment be committed to prison for not exceeding 10 days.

Under the provisions of the ordinance any vehicle, animal or motor, carrying 6000 pounds upon any wheel, which has a weight of less than 750 pounds per inch width of tire, shall pay a fee of $1, and as the weight is increased to 1000 pounds per inch width, which is the maximum, the fee is increased. It will be seen that this classification would include trucks of practically all sizes at the minimum fee, for the width of tire is such that the weight under the largest load is seldom in excess of 600 pounds an inch of tire width, but with the increase of capacity the weight on the rear wheels is often 70 per cent. of the weight of the machine and load and the weight on the rear wheels would be the basis on which the ordinance tax would be levied. With a very large number of motor trucks of capacity from five to 10 tons the weight on each rear wheel may range as high as 11,000 pounds, and yet, with a 14-inch tire and a load of 11,000 pounds this would be but 785 pounds to the inch of width. Such a load would be prohibited by the ordinance because of the weight per wheel, but it would be 215 pounds less than the maximum load per inch of tire width.

It is impossible to analyze the innumerable phases that might result in the limited space available, but it is obvious that the ordinance, while considering and licensing surface pressure, prohibits the use of larger vehicles, having rubber tires, that cannot be regarded from any point of view of having the destructiveness of iron or steel tires.

The Motor Truck Club of New York has been conducting a very vigorous campaign against the passage of the ordinance, and in this it has the co-operation of the Society of Automobile Engineers, the Automobile Dealers' Association and differing bodies of owners of horse vehicles. At the April meeting of the club Charles Emerson Gregory, consulting engineer of the borough of Manhattan and secretary of the board of consulting engineers of the city, was present to explain to the club some phases of the measure and what it was intended to accomplish. Mr. Gregory stated very frankly that it was intended to increase the revenue of the city and that the receipts of the license bureau would go to the general fund and not to the improvement of streets; that the streets of the city were not enduring under the constantly increasing traffic, and that it was believed best to limit the weights with a view of protecting the streets so far as possible; that the limitation of width of vehicles was intended to facilitate traffic. He answered vary-

ing questions from the viewpoint of the board he represented and it was developed that the streets were very generally not constructed for the heavy traffic. It was necessary to either prohibit excessive weights or to make those using the heavy vehicles pay for the use of the streets.

In the discussion it was developed that the engineers who were responsible for the ordinance had a very vague knowledge of rubber tires and their influence upon paving, and statements were made relative to the use of such tires that evidenced there had been no consideration of the difference between the rubber tire of the motor truck and the steel tire of the animal vehicle. In other words, it was proposed to tax motor trucks on the theory that they were as destructive of paved streets as are steel tires. That a rubber tire will have a contact area of sufficient size to reduce the actual surface pressure to a very small part of what was allowed for steel tires by the ordinance, was apparently lost sight of.

The fact was pointed out by J. S. Bernstein, a traffic engineer, that the ordinance was based on the assumed destructive influence of all vehicles on the streets, but the ordinance would permit this destruction to go on by the payment of additional fees, instead of prohibiting it; that the improvement of traffic was possible by better regulation and the elimination from the streets of standing vehicles; that it would be possible to have haulage done at night instead of by day; that certain streets could be set aside for differing forms of traffic; and, finally, that there was not only no knowledge of the influence of travel on the streets, but the city evidently proposed to continue to construct streets that were not suited for the heavy work upon them.

The ordinance was discussed to considerable length and from differing aspects by the members of the club, and it was the unanimous opinion that were it to become operative it would be a very great obstacle to the utilization of motor trucks, and with some it would be prohibitive, for one of the greatest economies from their use is the loads that can be carried. It was stated that the club had asked for a hearing on the ordinance and had enlisted other organizations to campaign against its adoption. The differing bodies were very anxious to prevent it becoming a city law, and were united in their opposition. In connection with this it was pointed out that such an ordinance might result in retaliatory ordinances in the adjacent towns and cities, and there might be additional burdens placed upon the owners.

At Omaha the postmaster is experimenting with the collection of the mail by motor car, and in comparison with horses the work is accomplished in about half the time. The routes range from a quarter mile to four miles length, and in trials with light machines there was but little gain made with the long as compared with the short runs, the average being practically the same.

OLD OFFICERS ARE CHOSEN.

Boston Commercial Motor Vehicle Association Re-Elects Its Board of Executives.

The members of the Boston Commercial Motor Vehicle Association were so well satisfied with the old officers that they were re-elected at the annual meeting of the organization held April 19. The only change was necessitated by the retirement of Kenneth M. Blake, for a number of years manager of the Boston branch of the Locomobile Company of America, who resigned that position to associate himself with the International Motor Company at its New York office. Mr. Blake had been a director from the organization of the association. His place was filled by C. P. Rockwell, manager of the Thomas B. Jeffery Company, maker of the Jeffery delivery wagons. The election resulted as follows:

President, J. S. Hathaway, manager of the Boston branch of the White Company; vice president, J. W. Maguire, president of the J. W. Maguire Company, agent for the Pierce-Arrow trucks; treasurer, Day Baker, New England district manager for the General Vehicle Company; clerk, Chester I. Campbell; directors, Alvan T. Fuller, president of the Packard Motor Car Company of Boston; E. A. Gilmore, of the Whitten-Gilmore Company, agent for the Federal wagons and Standard trucks for New England; J. H. MacAlman, of J. H. MacAlman & Co., agent for the Stearns truck; A. P. Underhill, of the Underhill Company, agent for the Knox gasoline and Grinnell electric vehicles; J. W. Bowman, of the J. W. Bowman Company, agent for the Waverley electric wagons and trucks, and C. P. Rockwell, of the Thomas B. Jeffery Company.

SECURES PITTSBURG PLANT.

Model Gas Engine Works to Enlarge Its Present Facilities by Adding Another Factory.

The Model Gas Engine Works, Peru, Ind., maker of gasoline engines, for automobiles, tractor engines, clutches and transmissions, has purchased four acres of land fronting on the railroads at Pittsburg, Penn., and a factory will be built to cost $200,000, and to be in operation Sept. 1. The Peru plant will be operated as formerly and there will be little change in the company's organization except that men of considerable wealth will be added to the directorate and the capital will be increased to $750,000.

The Peru concern is of long standing and having outgrown capacity, labor supply and railroad facilities at Peru, decided to establish the second plant at Pittsburg. Within three or four years extensions that will aggregate $500,000 will be made and the number of employees will be doubled. The new company will be incorporated under the laws of Pennsylvania, the name being the Pittsburg Model Engine Company.

INDUSTRY PROTESTS AGAINST TARIFF.

A COMMITTEE consisting of John N. Willys, president of the Willys-Overland Company; W. C. Leland, general manager of the Cadillac Motor Car Company; Charles Clifton, treasurer of the Pierce-Arrow Motor Car Company; Hugh Chalmers, president of the Chalmers Motor Car Company, and Henry B. Joy, president of the Packard Motor Car Company, representing 27 different concerns manufacturing pleasure cars and service wagons, has in charge a very strenuous protest that is raised to the passage by Congress of the Underwood bill revising the tariff in the form that it now has with reference to the automobile industry.

This group of manufacturers includes the Autocar Company, Philadelphia, Penn.; American Locomotive Company, New York City; American Motors Company, Indianapolis, Ind.; Chalmers Motor Company, Detroit; Cadillac Motor Car Company, Detroit; Cole Motor Car Company, Indianapolis, Ind.; Garford Company, Elyria, O.; Haynes Automobile Company, Kokomo, Ind.; Hupp Motor Car Company, Detroit; Locomobile Company of America, Bridgeport, Conn.; Kissel Motor Car Company, Hartford, Wis.; Lozier Motor Company, Detroit; Mitchell-Lewis Company, Racine, Wis.; National Motor Vehicle Company, Indianapolis, Ind.; Oakland Motor Car Company, Pontiac, Mich.; Olds Motor Works, Lansing, Mich.; Packard Motor Car Company, Detroit; Peerless Motor Car Company, Cleveland, O.; Pierce-Arrow Motor Car Company, Buffalo, N. Y.; Pope Manufacturing Company, Hartford, Conn.; Reo Motor Car Company, Lansing, Mich.; Staver Carriage Company, Chicago, Ill.; Stevens-Duryea Company, Chicopee Falls, Mass.; Studebaker Corporation, South Bend, Ind.; Warren Motor Car Company, Detroit; White Company, Cleveland, O.; Willys-Overland Company, Toledo, O.

In the Underwood tariff bill finished automobiles and automobile bodies are to be subject to a customs duty of 45 per cent., which is the same as they are taxed for import by the Payne-Aldrich tariff now in effect, but the Underwood bill establishes the tax on automobile chassis at 30 per cent. and finished parts of automobiles, not including tires, at 20 per cent., both of which were taxed at 45 per cent. by the present tariff.

It is maintained that the proposed bill, because of the reduction on the two classifications stated, is opening the American market to foreign manufacturers and foreign workmen at the lowest possible terms; that the importers and representatives of foreign automobiles were consulted and their advice taken, but the American manufacturers were in every way ignored.

It is further maintained that at the hearing before the ways and means committee of Congress representation was made by Charles H. Sherrill, representing the American Importers' Salon, that only slight modification of the existing tariff was necessary to be entirely satisfactory to European factories. (See tariff hearings, 60th Congress, schedule C, part two, pages 2659-2717.) Mr. Sherrill stated that the duty should be reduced from 45 per cent. to 30 to 33 per cent. to give the European manufacturers entry into the American market at a rate of profit that would be satisfactory. In addition, a plea was made for similar reduction by the Italian Chamber of Commerce of New York City.

The duty on finished automobiles is not reduced, but the word "chassis" at 30 per cent., means a reduction of 33 per cent. Abroad machines are generally sold without bodies, each purchaser as a rule having his equipment built to meet his own ideas. There are other factors than the choice of the buyers that entail this policy. The European automobile builder has practically completed his production in the chassis. There are those who will undertake to furnish the body and equipment, but this business is not regarded as being essential to motor vehicle manufacturing. It is this condition or aspect that has caused the protest from the American industry. Under the provisions of the bill the foreign chassis, which represents to the industry abroad what the completed vehicle does here, could be sold here for a price that would make such competition felt very keenly with reference to the higher grades of machines. To illustrate: A machine that would sell in England, for instance, for $3000, would cost here today with the duty added, exclusive of freight, $4350. Under the proposed tariff this price would be reduced to $3900. The European manufacturer could sell for the same price as now, the importer would make the same profit, and the machine could be sold at $450 less and naturally at a parity with American automobiles of the same market value.

Taking the parts clause: Assuming that the components of a chassis that would sell for $3000 abroad when assembled were shipped to this country in quantities and assembled here, the difference of 25 per cent. would mean that assembling plants for foreign machines could, and no doubt would, be established here, and the difference in price would mean a distinct selling advantage. It is claimed that this section of the tariff would encourage the establishment of American assembling plants for foreign automobiles, and that the only chassis imported would be those of the manufacturers who have not the resources to assemble their machines here, or by the occasional purchaser who bought his vehicle abroad. One handicap to foreign competition is the difficulty of obtaining parts and the same character of service given by American automobile manufacturers to their customers. Now it is necessary for the importer of motor cars to keep a stock of components to meet requirements of normal wear and use. Were assembling plants established this would place the foreign manufacturers on precisely the same footing as the Americans so far as obtaining parts and service is concerned.

American automobiles have practical worth and utility that is recognized abroad, and the exportations

have increased very largely. These markets have been developed at enormous cost and furnish an outlet for a considerable proportion of the production of some concerns. Whatever development the industry has made of the foreign markets has directly benefited the American wage earners. American productions have to combat popular opinion and in some instances strong prejudice in Europe. In America there is a prevailing sentiment that the foreign production is superior or has greater value. What is feared by the industry is that the experience with all other classes of imports will be repeated with automobiles, and, in the final analysis, the people as a whole must pay the price. The theory that the cost falls on the purchaser alone is absolutely without foundation.

MAGNALIUM MOTOR PARTS.

Different Experiments Show Great Endurance of a Very Light Aluminum Alloy.

Considerable attention has of late been directed toward magnalium, an aluminum alloy that has high resistance to corrosion, and is lighter, stronger and easier to work than aluminum. Different tests have been made and the results of these appear to indicate that the metal has met the requirements for strength and endurance, showing no evidences of wear under conditions of extreme stress. A paper was recently read before the Society of Automobile Engineers, Metropolitan Section, by Morris R. Machol, on the subject of "Lightweight Reciprocating Parts for Motors," in which the use of magnalium, an alloy of aluminum and magnesium, was reviewed. The specific gravity of magnalium is 2.5, as compared with 2.56 for pure aluminum, 2.82 for aluminum alloy No. 12, and 7.5 for cast iron. This metal has been used for cylinders and with iron pistons and has endured in engine work with a surprising degree of satisfaction, and it is maintained that magnalium pistons ought to similarly endure in cast iron cylinders.

The ordinary grade of cast iron used for pistons has tensile strength from 18,000 to 20,000 pounds, and magnalium has tensile strength of about 23,000 pounds the square inch and is very tough, the brittle quality of cast iron being lacking. Magnalium is held to be a better bearing metal than bronze or babbitt. For piston material an advantage is the reduction of vibration. While the melting temperature of the metal is 1250 degrees Fahrenheit at atmospheric pressure, and this heat is often exceeded in an engine cylinder, the magnalium piston is held to endure because it never reaches a critical point, the heat being radiated to the cylinder walls because the thermal conductivity of magnalium is 14 times as great as cast iron. As the dome of the magnalium piston is cooler than that of a cast iron piston the probability of preignition is minimized.

As the influence of the inertia forces can be reduced by using light weight pistons, the bearing friction is correspondingly reduced, and this means an increase of horsepower. The use of magnalium pistons is maintained to lessen the stress on the connecting rods and reduces the wear on the connecting rod bearings, and, indirectly, on the crankshaft bearings. The quality of the magnalium will permit the making of the wrist-pin bearings in the pistons, this construction insuring very good results. The light magnalium piston permits rapid acceleration of the engine. Where magnalium has been used for connecting rods the metal was machined for bearings and the rods have endured quite as well as where other types of bearings were fitted.

AUTO 'BUS LINES FOR NEW YORK.

Legislation Enacted That Will Allow Their Establishment in the Metropolis.

For a number of years the people of New York have been denied transportation in the metropolis other than that afforded by the elevated and surface roads and the subways save in Fifth avenue, where the motor coaches have done a very satisfactory and lucrative business. The law just amended provided that it was necessary for any company proposing to serve the public to have the consent of a company having a franchise if the route was to be in a street where a track of a traction company was laid for 1000 feet or more. The application of a company that proposed to give the public the benefit of a motor omnibus service, filed with the bureau of franchise, directed the attention of the New York board of estimate to the law and remedial legislation was formulated and was passed.

The amended law provides that omnibus lines shall have the same standing as traction companies and places them under the jurisdiction of the board of estimate of the city and the state public service commission, and these bodies are authorized to establish routes and to grant limited term franchises for the operation of omnibuses. The amendment was opposed by the New York City Railways Company and the Brooklyn Rapid Transit Company, it being maintained that the omnibus lines would carry a considerable part of the profitable short haul passengers and the unprofitable long haul passengers would be left for the traction companies. The necessity of relieving congested traffic was the principal argument in behalf of the measure.

The passage of this bill makes practical, and probably possible, the establishment of at least several companies which have sought franchises to operate omnibus lines, and one of these proposes to utilize 1000 passenger vehicles if it is given the authority to do so. There is now a company that has been seeking a franchise for a considerable length of time that desires to establish a service in Fifth avenue and proposes to utilize electric vehicles. This company promises that with the granting of a franchise it will immediately procure equipment and can begin service within a comparatively short time.

THE REASONS FOR ELECTRICS.

Conclusions of an English Writer for the Rapid Increase of This Class of Vehicle.

That there are approximately 30,000 electric vehicles in service in the United States, of which a third are used for freight and the remainder for pleasure, is the subject of a very interesting review by a writer in the Commercial Motor, one of the leading English publications devoted to highway transportation. It is maintained by this authority that about 4000 machines were produced in 1912 and that at least 5000 will be built in 1913. Considering these facts it is deduced that either England is slow to adopt a means for carrying freight that has been proven practicable elsewhere, or the conditions in England are not favorable for this type of machine.

Reflecting upon factors, it is believed that the roads of England are better and that electrics could be more economically used, while it is held that there are abundant facilities for constructing machines and there are those who would consider electric haulage were there a reasonable return on the investment. One conclusion is that the electric is only serviceable for the short hauls, and that it is most generally used where the work is short haulage and frequent stops in the United States. It is stated that electrics in the United States have not taken the place of gasoline conveyances, but have replaced horses. One of the reasons for horse replacement is held to be the severe winters and torrid summers of the United States, which "makes horse traction almost impossible," in support of which is cited the loss of animals because of the extreme heat of the early summer of 1911. It is further commented that many of the first cars built in Amercia were electric, "as the adaptation of a good electric motor in the last decade was easier than coaxing an unruly petrol motor." The limitations of the early batteries and the improvements made in them are instanced.

It is observed that with the betterment of the batteries attention was directed toward making the operation of electric vehicles commercial possibilities, the chief qualities of the machines being silence, simplicity of operation and low cost of tires, which was supplemented by the manufacturing companies establishing service stations where attention was promotive of general use. But regarding the promotion of the electric power wagon, it is stated that these were preferred by some because of the absence of vibration and odor of gasoline vehicles; that with others the lower insurance rates and the exclusion of gasoline machines from the docks and piers were distinct influences; and that "after proving successful in these fields the manufacturers became bolder and proved to the large express companies that, for short haul and city transfer work, the light electric wagon was more economical than the horse. The light petrol delivery wagon three or four years ago was far from the efficient vehicle of today, in fact the American ones at that time were little removed from glorified pleasure chassis. English built vans of the class were kept out by the tariff."

Going further, the writer is of the opinion that the construction of electric railroads was an object lesson in the possibilities of electric transportation, but he refers to the condition of the roads as a whole as not such as to justify the use of motor vehicles for "long hauls," and maintains that because of the character of the highways interurban motor transit of over an area of 30 or 40 miles radius is impracticable, owing to the heavy depreciation of the vehicle.

In other words, the writer believes that the limitation of motor traffic to within practically 20 miles from a commercial centre, because of the poor roads, has been a reason for the utilization of the electric vehicles in American cities and towns. This remarkable view of the motor vehicle possibilities is the more remarkable from the fact that it reveals so little knowledge of America, and it is decidedly interesting because it is published in what is regarded as being at least a dependable source of information.

KELLY-SPRINGFIELD BRANCHES.

Maker of Kelly Trucks Establishes Chain of Service Stations Throughout the Country.

The Kelly-Springfield Motor Truck Company, Springfield, O., maker of Kelly trucks, has announced a chain of 14 factory branches and service stations in the principal centres of the country, in order that first class service may be given to the users of its products. The branches are located at the following points: New York City, Chicago, Philadelphia, Cleveland, O.; Dallas, Tex.; Seattle, Wash.; Birmingham, Ala.; New Haven, Conn.; Kansas City, Mo.; San Francisco and Los Angeles, Cal.; Boston and Worcester, Mass.; Providence, R. I.

Each branch is in charge of a manager who is also district manager for the surrounding territory. Several more factory branches will probably be added in a short time. In no case is an agent in the smaller cities more than a few hours distant from a service station and his supply of repair parts, etc., can be augmented in a short time.

The Motor Truck Club of New York City, which is an organization composed largely of men identified with the industry, trade and differing transportation interests, has been established in permanent headquarters in room 1004 in the United States Rubber Company's building, at Broadway and Fifty-eighth street. Previously the office of the club was at 1845 Broadway, where the members met very frequently at lunch, and where the monthly meetings were held. The office is well furnished, has many conveniences, and at it much desirable information is available for the members and visitors.

VULCAN WINNER OF ECONOMY TRIALS.

IN AN economy trial during May 5, 6, 7 and 8, and in competition with 17 machines over a route of 288.7 miles, from Washington, D. C., to Hagerstown, Md., Harrisburg, Penn., Hanover, Penn., and Washington, a Vulcan four-ton truck carried its load at a cost of 1.22 cents a ton-mile, making it the sweepstakes winner. There was no other vehicle entered in the same class. There were seven divisions and a section of non-contestants, making eight in all.

The trials were promoted for the benefit of business men of Washington and vicinity, and the interest of the national government was evidenced by the observation of the machines and the work accomplished with them by a number of departmental officials and attaches.

The route for the first day called for a drive of 68.9 miles, with a noon stop at Frederick, distant 43 miles from the start. The second day the way was to Harrisburg, 70.7 miles, with the noon control at Shippenburg, 32 miles from the start. The third day the route was to Columbia, Penn., 31.5 miles, where the stop was made at noon, and then on to Hanover, 65.3 miles. The last day the run was to Baltimore, 43 miles, and thence to Washington, the total for the day being 83.8 miles.

Each machine was required by the rules to carry its rated capacity of freight, or to be subject to a penalty for the shortage. The entrants in the several classes were: Division No. 1K, 1000 pounds or less capacity—Hupmobile No. 9, 800 pounds; International Harvester, No. 19, 1000 pounds. Division No. 2K, 1001 to 1500 pounds capacity—White No. 17, 1500 pounds; Atterbury No. 13, 1500 pounds; Atterbury No. 20, 1500 pounds. Division No. 3K, 1501 to 2000 pounds capacity—Wilcox No. 5, 2000 pounds; Atterbury No. 14, 2000 pounds; Little Giant No. 3, 2000 pounds. Division No. 4K, 2001 to 3000 pounds capacity—Mais No. 2, 3000 pounds; Witt-Will No. 4, 3000 pounds; McIntyre No. 10, 3000 pounds; Autocar No. 11, 3000 pounds; Atterbury No. 15, 3000 pounds; White No. 18, 3000 pounds. Division No. 5K, 3001 to 4000 pounds capacity—Lauth-Juergens No. 12, 4000 pounds; Atterbury No. 16, 4000 pounds. Division No. 6K, 4001 to 5000 pounds capacity—Rowe No. 8, 5000 pounds. Division No. 8K, 8000 pounds capacity—Vulcan No. 1. Non-contesting division—United States ambulance; Brown No. 100, capacity eight persons; Four-Wheel-Drive No. 101, capacity eight persons; White No. 102, capacity eight persons.

The rules of the competition were very carefully applied and the greater part of the penalties were for adjustment or attention that would be expected under normal conditions of operation, and which were as trifling as adjusting carburetors, replenishing oil and water, cleaning gasoline supply pipes, and the like, and beyond this were broken chains, leaks in radiators, and happenings of minor consequence. The only serious condition to eventuate was the breaking of the front differential of the Four-Wheel-Drive ambulance, and even with this mishap the machine finished, driving through the rear wheels only. The Vulcan truck was heavily penalized when it was forced to shed half its load because of the inability to obtain traction of the Middlebrook hill the first day. Having climbed the hill with the half load, this was taken off and the truck returned for the remainder. At the top of the hill the full load was put on and the run continued. The penalization was for time lost and not for mechanical faults.

In arriving at a score the cost of gasoline was 20 cents a gallon and oil 45 cents a gallon. The penalties for loss of time or work on the road was figured at 1000 points representing $1, a technical inspection for broken parts on the same basis, and a trial of the brakes, clutch and gearset. Taking the aggregate of these and the cost of fuel as stated the scores were computed.

The scores show the following:

No.	Make	Road Penalty	Other Penalty	Total Penalty
2	Mais	0	0	0
5	Wilcox	0	0	0
10	McIntyre	0	0	0
18	White	0	0	0
19	I-H-C	0	0	0
102	White	0	0	0
8	Hupmobile	8	0	8
13	Atterbury	16	15	31
100	Brown	23	2	25
16	Atterbury	32	1	33
11	Autocar	35	1	36
3	Little Giant	12	31	43
17	White	30	15	45
4	Witt-Will	65	1	66
14	Atterbury	69	1	70
15	Atterbury	123	1	124
12	Lauth-Juergens	132	1	133
8	Rowe	125	33	158
20	Atterbury	155	5	160
1	Vulcan	217	20	237
101	Four-Wheel-Drive	297	175	472

The results by divisions, together with the total cost from which the score is obtained by dividing by 288.7 (the mileage) is as follows:

	Division 1K, 1000 Pounds or Under, Speed 12 Miles.			
19	I-H-C	1000 pounds	$5.01	$.0347
9	Hupmobile	800 pounds	5.48	.0474
	Division 2K, 1001 to 1500 Pounds, Speed 12 Miles.			
17	White	1500 pounds	$5.16	$.0238
13	Atterbury	1500 pounds	6.05	.0279
20	Atterbury	1500 pounds	9.04	.0417
	Division 3K, 1501 to 2000 Pounds, Speed 11 Miles.			
5	Wilcox	2000 pounds	$7.52	$.0260
14	Atterbury	2000 pounds	7.81	.0270
3	Little Giant	2000 pounds	8.00	.0277
	Division 4K, 2001 to 3000 Pounds, Speed 10 Miles.			
18	White	3000 pounds	$6.10	$.0140
10	McIntyre	3000 pounds	7.85	.0181
11	Autocar	3000 pounds	7.96	.0183
15	Atterbury	3000 pounds	8.02	.0185
2	Mais	3000 pounds	9.55	.0220
4	Witt-Will	2500 pounds	9.36	.0289
	Division 5K, 3001 to 4000 Pounds, Speed 10 Miles.			
16	Atterbury	4000 pounds	$9.96	$.0172
12	Lauth-Juergens	4000 pounds	12.38	.0214
	Division 6K, 4001 to 5000 Pounds, Speed 10 Miles.			
8	Rowe	5000 pounds	$18.96	$.0262
	Division 8K, 8000 Pounds, Speed Eight Miles.			
1	Vulcan	8000 pounds	$14.95	$.0122
	Non-Contesting Ambulances.			
102	White	Eight persons	$5.98	$.0276
101	Brown	Eight persons	9.59	.0442
102	Four-Wheel-Drive	Eight persons	11.43	.0525

BRIEF NEWS OF MANUFACTURER AND THE TRADE

Manager L. A. Hailey of the Chicago branch of the Motz Tire & Rubber Company, Akron, O., maker of Motz tires, has added Charles R. Serfass and S. F. Frensdorf to his sales staff. Both men are considered among the foremost tire salesmen in the country.

Harry S. Houpt, who recently resigned as sales manager of the American Locomotive Company, New York City, maker of Alco trucks and pleasure cars, has been elected vice president of the Gurney Elevator Company. He will have charge of installations of more than $50,000 and will locate his office in New York City.

Frederick C. Benson, who was formerly associated with C. A. Benjamin in the Packard garage at Syracuse, N. Y., has taken an important position in the sales department of the American Locomotive Company, New York City, maker of Alco cars and trucks, to which place he was appointed by Mr. Benjamin since the latter became general sales manager.

The White Company, Pittsburg, Penn., a factory branch of the White Company, Cleveland, O., maker of White trucks and pleasure cars, has recently completed and occupied its new salesroom and service station at the corner of Craig street and Baum boulevard. The structure is shown in an accompanying illustration and is something of an innovation, in that it is built on the side of a hill and is so designed that vehicles may enter from the street level both in the basement and on the main floor. Each floor has 15,000 square feet of space, the basement being devoted to housing heavy trucks and for storage purposes, the first floor to salesroom and offices and the second to the repair department, machine shop and stock rooms. More than $75,000 worth of repair parts are carried in stock and 50 people are employed.

New Salesroom and Service Station of the White Company in Pittsburg, Penn.

The Knickerbocker Motor Truck Company, New York City, maker of Knickerbocker trucks, has sold $250,000 in preferred stock in order to provide for a factory extension necessitated by constant growth.

The Chase Motor Truck Company, Syracuse, N. Y., maker of Chase trucks, is planning extensive additions to its plant. New buildings are being added for manufacturing purposes and the general offices will be enlarged to double their present size.

M. H. Carter, formerly with the Heppenstahl Knife & Forge Company, has been made eastern representative of the parts department of the Driggs-Seabury Ordnance Corporation, Sharon, Penn., maker of Vulcan trucks.

M. E. Grable, formerly with the Old Reliable Motor Truck Company, Chicago, maker of Old Reliable trucks, has been made manager of the New York branch of the Universal Motor Truck Company, Detroit, maker of Universal trucks, succeeding H. W. Walton.

The Menominee Motor Truck Company, maker of Menominee trucks, formerly the D. F. Poyer Company and previous to that D. F. Poyer & Co., has purchased 12 acres of land adjoining its present plant at Menominee, Mich., and additions to the factory will be built.

William P. Kennedy and Joseph A. Anglada, consulting engineers, are to open headquarters in the United States Rubber building, 1790 Broadway, New York City. Mr. Kennedy, who is a transportation expert, has for several years been prominently identified with the American Locomotive Company, New York City, and the Baker Motor Vehicle Company, Cleveland, O., the latter maker of Baker electric cars, as a consultant, while Mr. Anglada is probably best known for his work in developing demountable rims.

V. Link, chief engineer of the Universal Motor Truck Company, Detroit, maker of Universal trucks, has resigned. He is said to be the original designer of the Universal truck and is reported to contemplate entering business for himself.

W. A. Zimmerman, general manager of the Mercury Manufacturing Company, Chicago, maker of Mercury trucks, has established a branch at Boston, Mass., while George F. Kehew will look after the New England interests of the company. The service station and salesrooms will be located at 239 Massachusetts avenue, Cambridge, Mass.

The Electric Products Company, Cleveland, O., maker of the Wotton automatic battery charging panels, has moved from its congested quarters at 6536 Carnegie avenue, to its new building at 10514 Dupont avenue.

The Weller-Thomas Company, Zanesville, O., was recently incorporated by capitalists of that city and will erect a plant in which to manufacture motor fire apparatus.

The Kissel Motor Car Company, Hartford, Wis., maker of KisselKar trucks and pleasure cars, has opened what is said to be the largest building in the United States devoted to the sale and care of one make of automobiles. The service station provides 70,000 square feet of floor space and in addition to the separate salesrooms for the trucks and pleasure vehicles, contains a garage, machine shop, paint shop and stock room. The structure is three stories high.

The Veerac Motor Truck Company, Anoka, Minn., maker of Veerac commercial vehicles, has opened a branch at 247 West Forty-seventh street, New York City, with H. B. McGinley as manager.

The Murray County Auto Company has been formed at Slayton, Minn., and will erect a modern garage building on Main street, that city. All modern apparatus for repair work, etc., will be installed. The company will handle the KisselKar, Studebaker, Buick, Paige and Mitchell lines of pleasure cars and trucks.

Brooks F. Martin of Shinniston, W. Va., is to open a garage in the Holt building on Walnut street, Grafton, W. Va. He will handle the Oakland and Mitchell pleasure cars and the Bessemer and Gramm motor trucks.

The Kissel Auto Company, Los Angeles, Cal., and the Standard Motor Company of San Francisco, Cal., have been amalgamated under the name of the Pacific KisselKar Branch. An idea of the extent of the operations intended by this new company may be gathered from the fact that the corporation is capitalized at $500,000. This is the largest automobile company ever organized on the Pacific Coast, it is said. The incorporators are: W. H. Hughson and G. N. Emmons of San Francisco, H. K. Butterfield and E. Roger Stearns of Los Angeles and George A. Kissel of Hartford, Wis. The latter is president and Mr. Butterfield is vice president of the parent Kissel Motor Car Company, Hartford, Wis., and the new organization is formed to market KisselKar trucks and pleasure cars in the Pacific Coast territory.

The Ents Automobile & Battery Company, St. Louis, Mo., has opened its new electric garage and storage battery repair station in the downtown section of the city. The company will

make a specialty of caring for electric trucks. Mr. Entz was for over 12 years with the Electric Storage Company as engineer and manager of the Baltimore and St. Louis offices and for the past four years has been the western representative of the Philadelphia Storage Battery Company.

G. W. Felts has taken the interest of Mr. Bacon in the firm of Langford, Bacon & Myers, distributor of Lauth-Juergens trucks, made by the Lauth-Juergens Motor Truck Company, Fremont, O., and has been appointed vice president of the concern. He has established a branch house at Los Angeles, Cal., which he is managing, being assisted by Harry C. Collins, formerly head of the office of the Allis-Chalmers Company.

The Brown Car Corporation, New York City, distributor of Brown trucks, made by the Brown Commercial Car Company, Peru, Ind., has opened offices in the United States Rubber building. The members of the company are Harry W. Torney and W. P. Fargo. They were formerly in business at 52 William street and have a salesroom at 2000 Broadway.

The Brady-Murray Motors Corporation was recently incorporated at Albany, N. Y. Arthur C. Brady is president, Arthur T. Murray is vice president and sales manager, and J. M. Breitenbach is secretary, treasurer and service manager. The corporation will act as eastern distributor of Smith-Milwaukee and Maccarr gasoline trucks, Lansden electric trucks and Chandler pleasure cars. The general offices of the concern are at 30 Church street, New York City.

The Lincoln Motor Car Works, Chicago, maker of Lincoln trucks, has granted to the Lincoln Motor Sales Company, Los Angeles, Cal., the manufacturing rights for the Pacific Coast of the Lincoln half-ton wagon. Not only will this permit of more prompt delivery, but will save many freight charges. It is the intention of the sales company, of which John A. Meeks and B. F. Taylor are secretary and treasurer, and vice president and general manager, respectively, to manufacture 1000 vehicles the first year, establishing branches in all the principal cities on the Pacific Coast.

The Signal Motor Truck Company has been incorporated at New York City, with a capital stock of $350,000. The incorporators are: J. S. Coates, W. C. Floyd-Jones and F. C. Canfield.

The General Auto Trucking Company, New York City, has been incorporated with capital stock of $25,000. The incorporators are: Albert A. Benedise, Thomas G. Cannon and George W. Cannon.

J. Cross, cartage expert, has become associated with the Universal Motor Truck Company, Detroit, maker of Universal trucks.

Joseph Stern, formerly connected with Wyckoff, Church & Partridge, New York City, has taken the American rights for the sale of Commer trucks, and has opened an office in the Thoroughfare building, Fifty-seventh street and Broadway, New York City.

John A. Graham, formerly sales manager for the Westfield Motor Truck Company, Westfield, Mass., has entered the employ of the Sanford Motor Truck Company, Syracuse, N. Y., maker of Sanford trucks, as district manager, with headquarters at Boston. Mr. Graham is a mechanical engineer and was formerly a resident of Boston.

Otto Stoll, formerly manager of the St. Louis branch of the General Motors Truck Company, maker of G. M. C. trucks, has been appointed assistant sales manager, succeeding E. J. Kilborn, who has become general manager for the Chicago district.

Joseph D. Porter, who has been sales manager for the Garford Company, Elyria, O., maker of Garford trucks and pleasure cars, has retired and has been succeeded by George F. Russell, who has been acting as supervisor of Willys-Overland district managers east of the Missisipi river.

J. R. Coleman, formerly connected with the E. R. Thomas Motor Company, the Chalmers Motor Company, the Hudson Motor Company and the Packard Motor Car Company, has resigned his position as chief engineer and designer of the Atterbury Motor Car Company, Buffalo, N. Y., maker of Atterbury trucks. Mr. Coleman is well known to the trade, having started with the Thomas company in 1904, when that company was in its infancy. His most prominent previous connection was with the Hudson Motor Car Company, as assistant chief engineer to C. H. Taylor. The distinct change of design of the Atterbury line of trucks is representative of his class of work.

The Welch Plant at Pontiac, Mich., one of the General Motors group, will in future be known as Northway plant No. 2 and will aid the Detroit factory in the production of Northway motors. Since the Welch car was taken to Detroit for manufacture the Welch plant at Pontiac has made motors for the G. M. C. trucks. The change will make no difference in the number of employees.

The Royal Equipment Company, Bridgeport, Conn., maker of Raybestos brake lining, Duplex brakes and brake bands, and Gyrex, the mixer, has moved into its new building on Railroad avenue, which was recently completed.

Henry E. Riker & Co., distributor in Ohio and Indiana for Stewart delivery wagons, made by the Stewart Motor Corporation, Buffalo, N. Y., has purchased the Windermere garage building at 1356 Euclid avenue, Cleveland, O., together with a 35-year lease on the land. It will be known as the Windermere-Euclid garage and will be the headquarters of the firm.

W. B. Miller, vice president and director of the B. F. Goodrich Company, Akron, O., maker of Goodrich tires, has been replaced by D. M. Goodrich, Mr. Miller having withdrawn from the company.

The International Harvester Company, St. Louis, Mo., has leased the garage building at 3944-3946 Olive street, as a sales and display room for automobiles and trucks. The building is in one of the automobile centres of St. Louis and was designed for such tenancy.

The White Company, Boston, Mass., has under construction one of the largest and best equipped motor car and motor truck establishments in New England. It will be located on Commonwealth avenue and will contain every modern appliance known to the automobile industry.

The Janesville Motor Company, Janesville, Wis., has in process of construction a new garage and service building, which will embody every feature in modern garage service. Many special features of repair work will be cultivated. The company handles the Jeffery and Service motor trucks, and the National, Overland, Rambler, Cutting, Borland electric, Stutz, Chevrolet, Little, Herreshoff and Stanley steam pleasure cars.

The Twin City Motor Car Company, St. Paul, Minn., northwestern distributor for Saurer, Mack and Modern trucks, and the complete lines of Maxwell cars, recently moved into its new quarters, 163 West Sixth street, where one of the finest garages in that city is located. Gustav Michaud is in charge of the pleasure car sales and A. F. Williams handles the truck department.

L. F. Marshall, who was formerly with the United States Tire Company, is now with the solid tire department of the Swinehart Tire & Rubber Company, Akron, O., maker of Swinehart tires.

G. A. and F. J. Meyer, Detroit, have leased for three years the old marine engine plant on East Jefferson avenue, at the foot of Baldwin street. The building will be used for the manufacture of Oliver trucks, made by the Oliver Motor Truck Company.

The Motor Wagon Company, Detroit, has announced a new truck, which will be of 1000 pounds capacity and use a four-cylinder, four-cycle motor and three-speed selective transmission. In the past the company has manufactured only an 800-pound wagon with a two-cycle engine.

The National Can Company, Detroit, has entered the radiator field and will build radiators for motor vehicles under patents granted to Theodore Coffelder. Frank W. Doyle, formerly with the McCord Manufacturing Company, will have charge of the production. C. V. Jones, who has been connected with the Long Manufacturing Company of Detroit and Chicago, will have charge of the sales department.

The Michaelson Motor Company, Minneapolis, Minn., has been organized to manufacture pleasure cars and a three-wheel parcel car. The latter will use a two-cylinder, 10 horsepower motor, a multiple disc clutch and a two-speed transmission.

The Eclipse Wheel Company, Camden, N. J., has been formed with capital stock of $300,000 to make wheels for motor trucks and other motor vehicles. Those interested include F. R. Hansell, J. A. MacPeak and G. H. R. Martin.

B. F. Parker, formerly of Denver, Col., is promoting a motor truck concern at Salt Lake City, Utah, which is expected to erect a large factory and employ 3000 skilled workmen.

The Highland Body Manufacturing Company, Elmwood Place, O., has been formed with capital of $81,900 to make bodies for automobile trucks and pleasure cars. W. Morrison, J. M. Morrison, R. E. Simmons, Jr., G. P. Stimson and J. Wilby are the incorporators.

George McLaughlin of Erie, Penn., has organized a company which will be incorporated at $100,000 to manufacture motor trucks ranging from one to four tons. Those interested are: Charles T. Stewart, A. H. McQuitty, J. B. McLaughlin and George McLaughlin.

The J. A. Mais Commercial Car Company, Indianapolis, Ind., is being organized to manufacture a new 1500-pound truck, designed by J. A. Mais, a younger brother of A. F. Mais, formerly of the Mais Motor Truck Company, and now with the Studebaker Corporation, Detroit, maker of Studebaker commercial vehicles and pleasure cars.

Abendroth & Root Manufacturing Company, 50 Church street, New York City, has opened a sales office and service station at 278-280 Halsey street, Newark, N. J. A. G. Bogardus is manager of the truck department of the company and will make his headquarters at the Newark plant.

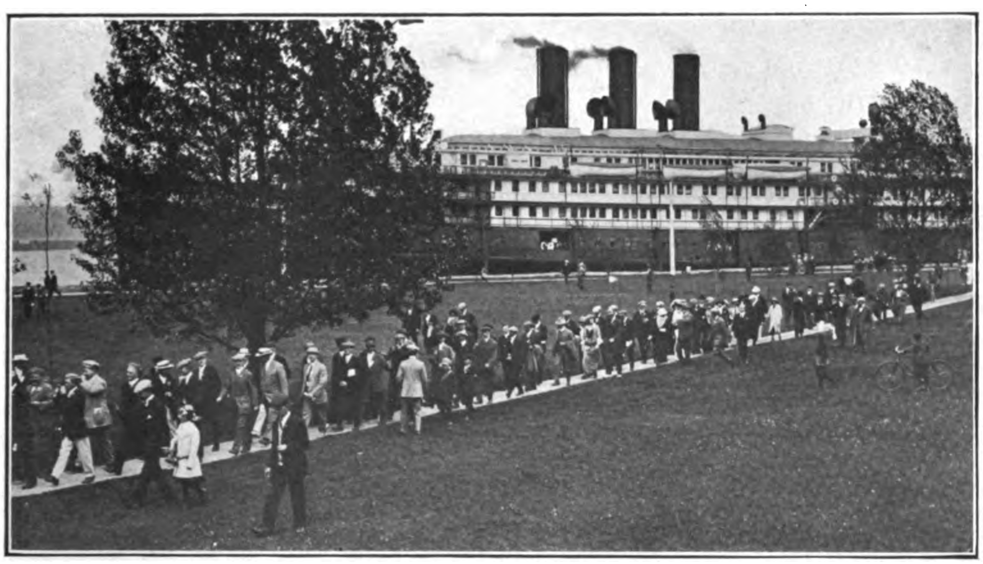
The MOTOR TRUCK
Devoted to Motor Driven Business Vehicles of All Classes.

VOL. IV. PAWTUCKET, R. I., JUNE, 1913 No. 6

BRITISH ENGINEERS INVADE AMERICA.

International Meeting of Institution of Automobile Engineers and Society of Automobile Engineers at Detroit Preceded and Followed by Tour of Industries--Hearty Welcome and Lavish Entertainment Mark Visitors' Trail.

FRATERNIZING with the members of the Society of Automobile Engineers, visiting some of the leading shops and factories of motor vehicle builders and makers of metals and components, being entertained with hospitality that threatened to ruin digestion because of its variance from custom, and rushing about the country in trains, steamers and motor cars in a manner that impressed them that American activity is a delirium, the English guests of the automobile industry of America have passed the most strenuous three weeks of pleasure that they have ever experienced. The English people live and do things differently than Americans, and this fact has been realized by the visitors, who have been shunted about the eastern section of the nation according to a schedule that was made up with the purpose of crowding into a given period sight-seeing and pleasure that was believed commensurate with the character of the event.

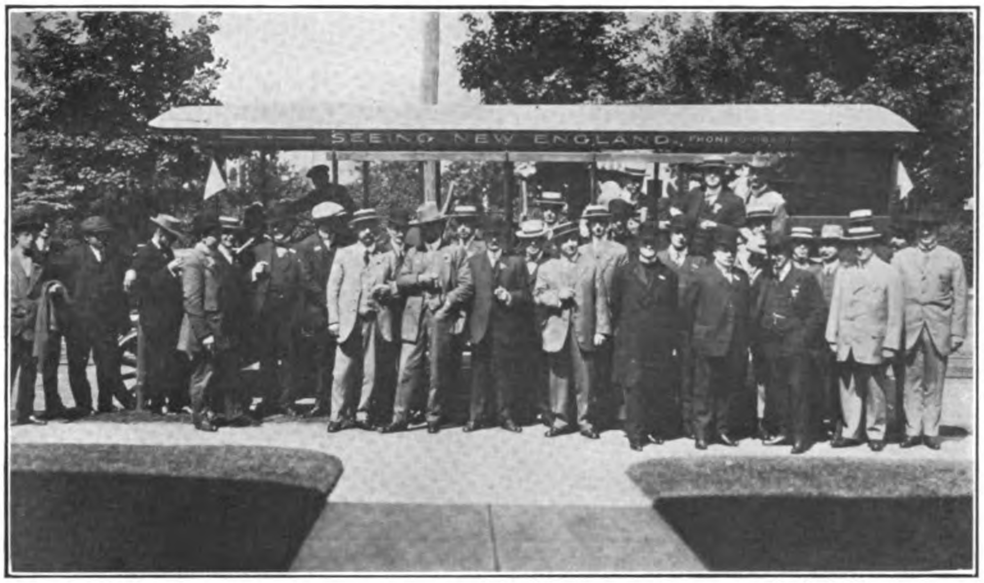


The Participants in the Lake Outing Disembarking from the Steamer City of Detroit III and Marching to the Plaza at Sault Ste. Marie.

The Americans entertained in relays, but there was only one group of Britishers, and whenever another city was reached an enthusiastic committee and a coterie of interested manufacturers saw to it that the programme was carried out with such additions as might be regarded as desirable. The English engineers maintained that never had they been so splendidly received and so courteously entertained, and for everything they had seen they had the highest praise, but one of them commented as the itinerary was nearing an end that he would sleep all the way as the steamship was returning.

While being driven to the factory of the American Locomotive Company at Providence the sightseeing 'bus was driven through Blackstone boulevard, a handsome residential part of the city, a series of shouts from the visitors aroused apprehension in the entertainers until the comment was heard, "I say, now, the first taste of England we've seen, y'know!" and there was the liveliest admiration, for it was maintained that "it was just like a country lane in England." The reply to this was that the simile might be expected, for the guests were in New England, a fact not generally realized.

Regarded by the industry as a whole the visit of the English engineers means a decidedly closer relation and a better understanding of America and American industrialism. The invasion of England by the Americans in 1911 created a fellowship that has been promoted by the visit of the Englishmen, and strong ties of friendship have been established that will no doubt have decided influence in both nations. The knowledge that each body of engineers has of the other, of the policies, practises and manufacturing methods, will be distinctly beneficial, and exchange of experience will no doubt be extremely



The New England Visitors on Their Arrival at the Plant of the Potter & Johnston Machine Company, Pawtucket, R. I.

The visitors sailed from Tilbury, England, May 17, on the steamship Minnewaska, leaving London the morning of that day, and the party that joined the ship consisted of the following: Institution of Automobile Engineers, T. B. Browne, president, London; T. C. Pullinger, Paisley, and Charles Wheeler, London, members of the council; Basil H. Joy, secretary, London; F. S. Bennett, London; Carl F. Benson, Coventry; C. A. Banston, Cambridge; H. Massac Buist, London; Thomas Clarkson, Chelmsford; E. G. Davison, New York; J. B. Ferguson, Belfast; F. E. Filer, London; J. Inglis Ker, Glasgow; J. A. Prestwich, Tottenham; R. W. Smith, Redditch; Mr. Smith, Jr., Redditch; E. B. Wood, Bristol; Lucien Bollack, Coventry; E. Wooler, Bristol. Society of Motor Manufacturers and Traders, J. B. Dunlop, Dubiin; C. Gilbert Moore, Twickenham; Tom Norton, Llandrindod Wells; E. C. Paskell, Birmingham. The ladies of the party included Mrs. T. B. Browne, Mrs. Thomas Clarkson, Mrs. T. C. Pullinger and Mrs. E. B. Wood.

The voyage was uneventful and the steamer reached New York the afternoon of May 26, but so late that the intended introduction to the great American pastime at the polo grounds was given over, and after reaching the Hotel McAlpin there was but little time remaining before the guests were novitiates at a "beefsteak dinner," where the evening was passed in social intercourse. Mr. Dunlop, who is notable from his invention of the pneumatic tire and the luxuriant beard he wears, was rather the hero of the cabaret entertainment. The committee of arrangements consisted of A. R. Cumner, chairman; A. L. McMurtry, R. McA. Lloyd, Howard Marmon and Secretary Coker

profitable. One of the facts impressed upon the visitors was the volume of manufacturing and the manner in which it is conducted. One of the party in commenting on his observations said that there has always been a disposition to discount the statements relative to the magnitude of the automobile industry in America and the number of vehicles in use, but he had reached a conclusion that the facts had been conservatively stated instead of being overdrawn, and the possibilities of motor vehicle transportation were almost unlimited.

The magnitude of the works visited, the character of the equipment, the qualities of the products, the systems and methods of manufacturing, the rapidity of production, the facilities for receiving and shipping, the attention given to employees' welfare, were features of the industrial plants visited, and it was the observation of the engineers that American manufacturing was on a mammoth scale. In the outward journey to Detroit the steel and tube mills of Pittsburg and McKeesport were seen, and those who journeyed into New England saw machine works that are justly considered as without equals anywhere in the world.

The English Engineers and Their Entertainers at the Factory of the American Locomotive Company at Providence, R. I.

F. Clarkson of the S. A. E., and the members were assisted in New York by the committee from the Metropolitan Section, which is composed of William P. Kennedy, chairman; Herbert Chase, secretary; L. P. Brown, P. P. Dean, Alexander Dow, N. P. Pope, H. M. Swetland, C. W. Fletcher, A. J. Slade, Joseph Tracy, H. C. Wilson, P. D. Wagoner, Roger B. Whitman and J. N. Anglada.

The following morning the party were taken in motor cars about New York, visiting Battery park, Wall street, the Brooklyn bridge, Prospect park, Brooklyn; Williamsburg bridge, the tower of the Woolworth building, and then the Automobile Club of America, where, after inspection of the laboratory, luncheon was served. The afternoon was devoted to drives about the city and a demonstration of the motor fire apparatus of the city was made by the courtesy of Commissioner Johnson for the benefit of the visitors.

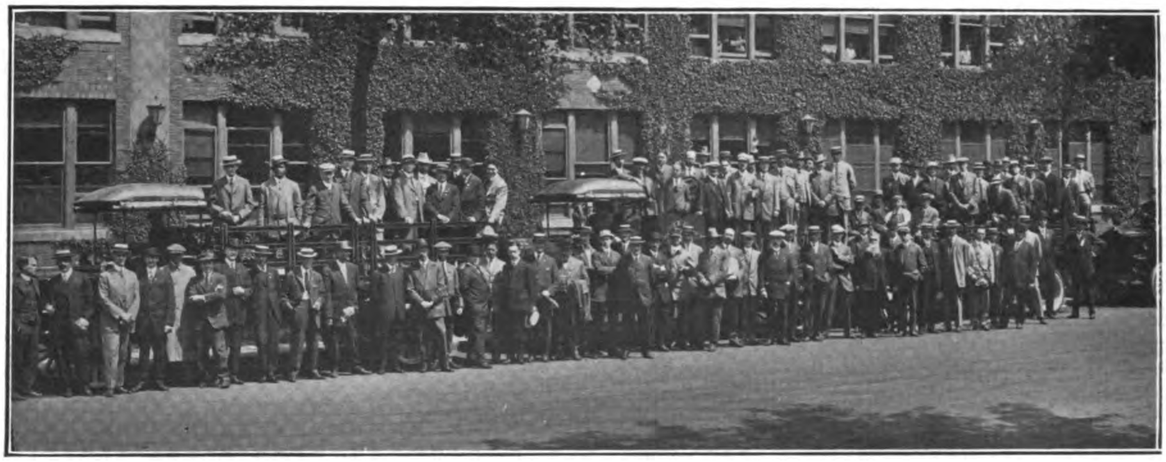
In the evening the regular May session of the Metropolitan Section of the S. A. E. was held in the ball room of the Hotel McAlpin, and the subject of the papers generally was "Motor Starting Devices," these being descriptive of different devices. The papers were read by the following: Prof. W. C. Marshall, Crescent air system; R. H. Coombs, Prest-O-Lite acetylene system; Alexander Churchward, Gray & Davis electric system; E. V. Hartford, Hartford electric system; B. Solawitch, Northeast electric system: W. E. Raignel, Disco acetylene system; H. L. Towle, Rushmore system; M. Wilson, Westinghouse electric system; Leonard Kebler, Ward Leonard electric system; Prof. Benjamin P. Bailey, Bailey electric system: M. Stow, Entz electric system; Charles A. Mudge, U. S. L. electric system; H. C. Gardner, Warner spring system. The reading of the papers was heard in part by members of the Electric Vehicle Association of America, who adjourned their regular monthly meeting early for the purpose of meeting the visitors. Because of the length of time required discussion of the papers was deferred until the midsummer session on the steamer after leaving Detroit.

The morning of May 28 the party, accompanied by Secretary Clarkson of the general committee of arrangements and several other members of the committee, left New York for Pittsburg in a special train that was chartered to take them through to Indianapolis. The party included about 20 members of the S. A. E. Reaching Pittsburg in the evening the train was side-tracked and the following morning the visitors were received by the Pittsburg reception committee, consisting of George L. Norris, chairman; Earl Blough, C. L. W. Rys, George W. Sargent, T. W. Schoepf and F. S. Slocum at the Pittsburg Athletic Association's club house, where breakfast was served. The ladies were entertained in several Pittsburg homes, and the men were first taken to the Homestead mills of the Carnegie Steel Company, special trolley cars taking them about the city.

The operations in the world's greatest steel works were observed with decided interest, and the engineers paid careful attention to the equipment and facilities of the mills. Later in the day a steamer took the party to McKeesport, luncheon being served on the boat, where the mills of the National Tube Company were inspected. On the return dinner was served at the Fort Pitt hotel, and after a reception the party returned to the special train, accompanied by a considerable number of Pittsburg engineers and members of the S. A. E., and the journey to Indianapolis was resumed.

Some of the Merrymakers in Fantastic Costumes Chosen for Invasion of Historic Island of Mackinac, Preliminary to the Sport.

The train reached Indianapolis the morning of May 30 and after breakfast the party was taken in charge by the Indianapolis committee, consisting of William G. Wall, chairman; George T. Briggs, Charles S. Crawford, Carl G. Fisher, W. O. Kenington, Howard Marmon, Harry C. Stutz and G. A. Weidley. The visitors were driven to the speedway, where a special stand was reserved for them. Here the international race was witnessed with intense interest, the visitors commenting that the track, had it the banking of the Brooklands circuit, would probably be equally as fast, while it has the advantage of permitting the specta-



Society of Automobile Engineers and the Institution of Automobile Engineers During the Visit to the Factory of the Packard Motor Car Company, Detroit, Mich.

tors to see considerably more of the racing.

The morning of May 31 the Indianapolis committee and the visitors were driven to the Wheeler & Schebler factory, where the production of carburetors was observed, and then the party was taken to the Prest-O-Lite factory at Speedway, where the operations incident to making and charging tanks with acetylene gas, and the use of acetylene gas engine starters were decidedly interesting. This concluded the business of the day and the next stop was made at the house of the Indianapolis Canoe Club, where luncheon was served. President Howard Marmon of the S. A. E. presided and there were speeches by H. O. Smith, president of the Premier Motor Manufacturing Company, President T. B. Browne of the Institution of Automobile Engineers, and C. A. Bookwalter, former mayor of Indianapolis. The party then was driven to Broad Ripple, where a clambake was served, and the remainder of the day was passed until the time for leaving for Detroit.

Arriving at Detroit the party was met by the local committee, consisting of Charles M. Hall, chairman; Howard E. Coffin, H. W. Alden and E. T. Birdsall, and after the visitors had been shown to their quarters at the Hotel Pontchartrain and had been comfortably established the day was passed in motor drives about the city and its suburbs. This was practically the first day that the Britons were not held to a schedule.

Monday, June 2, the first event was a visit to the Ford factory, the party numbering more than 100, and the English visitors were personally shown about by Henry Ford. If there was one thing more than another that amazed the invaders it was the speed of assembling the Ford cars, and they had abundant illustration of the results from organization, and one of these was the inspection of chassis at the rate of one every 20 seconds. The daily production of cars was then from 925 to 950 cars, but 1117 have been turned out in a single day. President T. B. Browne of the Institution of Automobile Engineers was shown a pile of engine cylinder blocks and asked to select one. He did so and marked it. Two hours later he was shown to a car in front of the factory and asked to take a little ride. On his return he was asked how the car run, and he said its performance was excellent. The hood was then lifted and he was shown the block of the engine he had marked after he had entered the factory.

A pleasant incident was the presentation of a Ford car to Secretary Basil H. Joy of the Institution of Automobile Engineers by George W. Houk, who represents the Rudge-Whitworth Company, maker of wire wheels, in this country. Mr. Houk lived in England for 14 years and knew Mr. Joy intimately the greater part of that time, and the gift was the result of an impulse, Mr. Houk buying the car and prevailing upon Henry Souther, former president of the S. A. E., to bestow it upon Mr. Joy. Before leaving Detroit Mr. Joy shipped the machine to Montreal and will take it to England from that port.

After lunch the visitors and their hosts were driven to the Cadillac factory, where they were welcomed by President H. M. Leland and divided into groups and shown through the plant by guides. The processes

The English Guests of the Society of Automobile Engineers Leaving the Hotel McAlpin for a Sightseeing Drive Around New York.

were observed with keen interest. Tea was served and the visitors were each presented a gold Cadillac fob before the party left the factory. A theatre party concluded the formalities of the day.

Tuesday, June 3, a tour was made of the Packard factory, where 15 pleasure cars and six freight wagons are produced daily, the annual production being 1200 cars and 1800 wagons. Here the methods in each department were given close attention, and the extreme care and precision taken to insure perfect work was noted with decided interest. When the tour had been completed the company was entertained at lunch by President H. B. Joy and the officers of the company. The afternoon was given over to a visit to the axle factory of the Timken-Detroit Axle Company. The production is now nine sets of axles for wagons and 130 sets of axles for pleasure cars each day.

The banquet in the evening at the Hotel Pontchartrain was the crowning event of the day. President Howard Marmon of the S. A. E. welcomed the company and the guests and expressed the thanks of both bodies for the freedom of the city, which had been formally extended in the form of engraved parchment communications to both societies. Howard E. Coffin was toastmaster and speeches were made by President T. B. Browne of the Institution of Automobile Engineers, by T. C. Pullinger of the same organization, and by H. M. Leland, president of the Cadillac Motor Car Company.

Wednesday, June 4, the morning was devoted to visits to the factories of the Hudson Motor Car Company and the Continental Motor Manufacturing Company, and lunch was partaken of at the plant of the Chalmers Motor Car Company. The party had at this time reached its greatest proportions. The members of both societies then returned to the hotel and left to embark on the steamer that left at 3 in the afternoon. The capacity of the City of Detroit III was taxed by the party, which numbered about 600, there being a goodly number of ladies. The afternoon remaining was passed in viewing the beauties of the Detroit river, Lake St. Clair and the St. Clair river, and the evening was given over to social intercourse.

Thursday, June 5, the summer meeting of the S. A. E. was begun at 10 in the morning. Following the address by President Howard Marmon came the report of the treasurer, the election of applicants for membership and new business.

At this meeting President T. B. Browne of the Institution of Automobile Engineers made formal expression of the appreciation of his party for the reception and entertainment, and presented to President Marmon an honorary membership in the body of which he is presiding officer. This is the first and only honor of the kind bestowed by the institution. Secretary Coker F. Clarkson was presented a silver card tray and Alden L. McMurtry, in charge of the transportation of the S. A. E., was given a handsome bit of silver plate.

The reports of the officers showed that the society had 1635 members, this evidencing a gain of 72 members, 91 associates and seven juniors since Jan. 1. The treasury contains a balance of $6,557.84. Henry Souther, chairman, made report for the iron and steel division and David Ferguson, chairman, made report for the ball and roller bearing division. Then came a series of papers as follows: "Manufacture and Physical Properties of Malleable Iron," by Enrique Toucedal; "A New Tensile Test Piece and Holder," by K. W. Zimmerschied; "Pneumatic Tires," by Paul W. Litchfield, and "Lubricating Oil," by Harry Tipper. These papers were discussed at length and then the "Design and Treatment of Leaf Springs" and "Worm Gears" were topics for consideration.

In the afternoon at 2 the session was resumed, this being for commercial vehicle subjects. The pa-

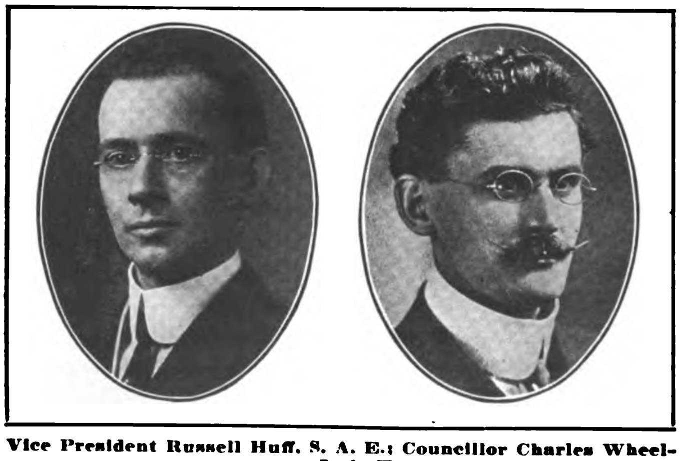
The Two Presidents: Howard Marmon, S. A. E.; T. B. Browne, I. A. E.

pers included the following: "Petrol 'Buses," by T. B. Browne; "Steam 'Buses," by Thomas Clarkson; "Calculating Depreciation of Commercial Automobiles," by Charles Wheeler, and "The Measurement of Horsepower," by E. B. Wood, all of whom are members of the Institution of Automobile Engineers; "Jackshaft versus Double Rear-Wheel Brakes," by Arthur Laycock, and "Metal Wheels," by Arthur J. Slade. These subjects were of particular interest to engineers engaged in freight vehicle designing and construction, and the papers by the English experts came in for close attention. At the conclusion of these, reports were made by William P. Kennedy, chairman of the truck standards division, and chairman of the commercial car wheels division. The topic for discussion was "Comparative Efficiency of Solid Motor Tires."

The steamer stopped for two hours at Sault Ste. Marie, and then continued on to the destination at Mackinac Island. A feature of the evening was a formal meeting of the "Bonnie Boys of Britain," in which the Englishmen made report as inspectors of the American automobile industry, and the raid by the Indiana Indians led by Big Chief F. E. Moscovics, in which five captives were lashed to a stake and after a council were sentenced.

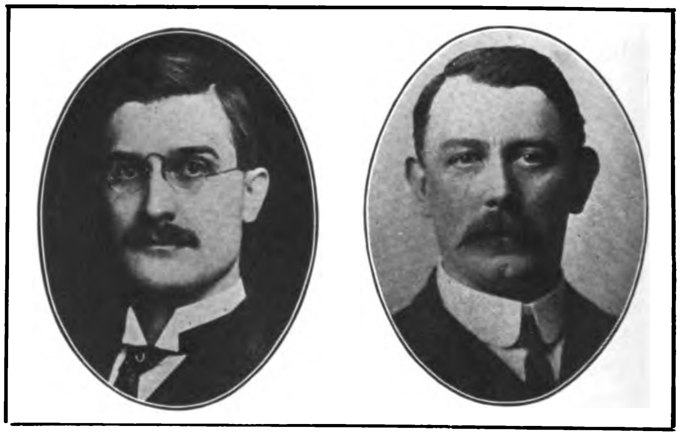
Friday morning the session was taken up by papers on "Automobile Production Inspection Methods," by E. F. Roberts; "Influence of the Sales Department on the Design of Motor Cars," by F. E. Moskovics; "Wire Wheels," by George W. Houk; "Motor Construction," by Claude E. Cox; discussion, these reports—electrical equipment division, by Andrew L. Riker, chairman; broaches division, by C. W. Spicer, chairman; pleasure car wheels division, by Henry Souther; nomenclature division, by Elliott J. Stoddard, chairman; miscellaneous division, by Arthur Holmes, chairman, and the consideration of these topics: "Electric Motor Starters," "Possibilities and Limitations of Utilization of Electricity in Operative Motor Car Functions," "Possibility of Weight Reduction in Motor Car Design" and "Hobbing Methods."



Vice President Russell Huff, S. A. E.; Councillor Charles Wheeler, I. A. E.

The steamer reached Mackinac Island at 2:30, where the engineers and their guests disembarked. A large number of the men appeared in improvised costume and the stop was given over to informal pleasure, and in the evening after the steamer was Detroitward bound the S. A. E. returned the entertainment of the Britons the evening before with a so-called play entitled "Reverse English on the Heat Treatment," which assumed the spirits of the English engineers in purgatory in the year 2000. This was a decidedly interesting diversion.

The morning of Saturday, June 7, marked the closing of the meeting, at which a paper was read entitled "Notes on Power Variations with Atmospheric Changes," by Herbert Chase, another on "A Consideration of Certain Problems of Carburetion," by Arthur B. Browne; a report was made by Chairman John O. Heinze for the motor testing division, and "Gasoline Motor Fuels" and "Motor Manifolds" were discussed. At this meeting the committee appointed at the first session to express the opinion of the society relative to the Oldfield patent bill, now pending in Congress, reported the following, which was unanimously adopted:



Vice President John G. Perrin, S. A. E.; Councillor T. C. Pullinger, I. A. E.

"Resolved: First, that the Society of Automobile Engineers is opposed to the Oldfield bill; second, that it is opposed to any fundamental changes in the patent law without thorough investigation and fair public hearings; and third, that a copy of this resolution be forwarded, on behalf of the society, to every senator and representative and to other engineering societies."

On arrival at Detroit the formalities incident to the meeting ended, and the English visitors lost three of their number, who left to make tours of the western

The Two Secretaries: Coker F. Clarkson, S. A. E.; Basil H. Joy, I. A. E.

states, and the remainder of the party and a group of the American organization left by boat for Cleveland, where they arrived Sunday morning. The headquarters was at the Hotel Statler. Sunday was devoted to sightseeing, and Monday visits were made to the White, Winton, Peerless, Baker and Rauch & Lang motor car factories, and to the plants of different manufacturing establishments that produce engines and components. A few elected to go to Akron and inspect some of the tire making plants. The party left that night by boat for Buffalo. The Cleveland committee consisted of G. R. Wadsworth, chairman; Harold B. Anderson, C. H. Foster, Christian Girl, L. H. Kittredge, John B. Hull, George E. Merryweather, Fred R. White, C. L. F. Wieber, Alexander Winton and C. B. Wilson.

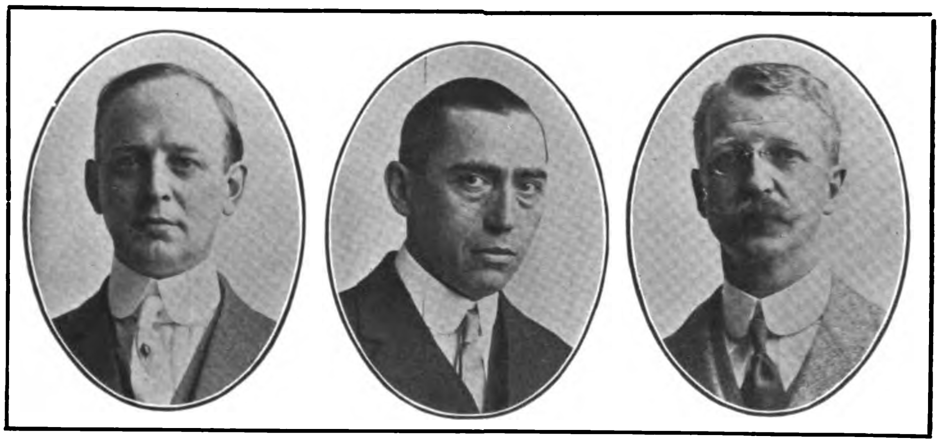
At Buffalo the party, then numbering about 50, was received by a committee made up of David Fergusson, chairman; W. H. Barr, L. H. Gardner, W. H. Ladd, Henry May, C. L. Sheppy and H. K. Thomas. After breakfast on the steamer the factory of the Pierce-Arrow Motor Car Company was visited, and in the afternoon the visitors were taken to Niagara Falls, the Pierce-Arrow Motor Car Company being the host at luncheon at the factory and at supper at Niagara Falls. At this point the English party divided, President and Mrs. Browne leaving for the West to continue a journey around the world, a number going to New York to sail on the Mauretania for England, June 11, and Secretary Coker F. Clarkson and A. L. McMurtry of the general committee took charge of a group consisting of F. S. Bennett, Carl T. F. Benson, Lucien Bollack, C. A. Cranston, J. B. Ferguson, E. C. Paskell, R. W. Smith, E. Wooler, Charles Wheeler, Mr. and Mrs. E. B. Wood and Secretary Basil H. Joy that had elected to make the visit to New England.

Pawtucket, R. I., was reached the morning of June 11 and the tourists were received by a committee consisting of F. P. Nehrbas, chairman; W. E. Biddle, C. B. Buxton, R. A. Downes, Earl Roberts, R. A. Vail and P. C. DeWolfe. Mrs. Wood was welcomed by a committee consisting of Mrs. F. P. Nehrbas and Mrs. W. A. Viall, who arranged a day of sight-seeing and a trip to Newport. The engineers were escorted to the To Kalon Club for breakfast, where they were the guests of James C. Potter, and then were taken to the works of the Potter & Johnston Machine Company, where they saw the operation of a very large equipment of automatic machinery and were provided with a series of blue prints showing the work and stating the material and the time required for the processes.

The party was conveyed to the plant of the American Locomotive Company at Providence, where the works were inspected, and after luncheon as the guests of the American Locomotive Company the mammoth shops of the Brown & Sharpe Manufacturing Company, one of the best known concerns of the world, which has more than 22 acres of floor space and employs between 8000 and 9000 men, was visited. The group, which numbered about 40 persons, was then taken to the Rhode Island Country Club for dinner, and the return to Providence was made to meet a special car that was a part of the 1:25 morning train for Bridgeport. Secretary Joy alighted with the party at Pawtucket, but returned to the train and continued on to New London, where he started for Montreal.

Thursday, June 12, the party visited the plant of the Locomobile Company of America at Bridgeport, where Andrew L. Riker was the local committee, and later on passed through the factory of the Spring Perch Company. After lunch, at which the Locomobile Company of America was host, the visitors were driven by motor car to New Haven, and there visited the shops of the New Haven Carriage Company.

The Hotel Taft was headquarters for the night. Friday, June 13, the party went to Hartford in the morning and there was met by Harold L. Pope, the local member of the committee. The shops of the Pratt & Whitney Company, the Pope Manufacturing Company and the Hartford Rubber Works Company were visited. The Pope Manufacturing Company was the host at luncheon. In the afternoon at 4 the visitors left by boat and enjoyed a sail down the Connecticut river and through Long Island sound, reaching the city of New York the following morning.



Members of American Committee of Arrangements: Left to Right, A. B. Cumner, Chairman; Allen L. McMurtry and Robert McA. Lloyd.

POWER WAGON DESIGN AND SERVICE.

The paper by Charles Wheeler, councillor of the Institution of Automobile Engineers, was on "Calculating Depreciation of Commercial Automobiles," as follows:

Depreciation has been defined as the diminution which takes place in the value of a wasting asset in spite of the amount expended on it in repairs, and there is no doubt that in assessing the diminution in value of commercial vehicles something more than the application of definite accountancy principles is necessary. This is probably true as applied to all factory accounting, which in effect is dissection as opposed to combination, the usual operation of commercial accounting.

If exception be taken to this short paper on the ground that the subject treated is more of a commercial than of an engineering character, I would point out that the scientific keeping of accounts connected with automobile production and the running of automobiles is of vast importance, and necessitates expert engineering advice in nearly all departments. In fact, the engineering head must not only know what cost he is "up against" on the score of depreciation, but he must have a big voice in the determination of the governing factors.

The first factor to be considered is the estimated "working life" of the automobile, and this depends very largely on the particular circumstances in which the vehicle is used. Thus a Maudslay motor 'bus runs some 700 miles a week, while a Maudslay stores van averages say 140 miles per week. Obviously, other things being equal, the length of the "working life" must be considerably in favor of the stores van. The "working life" also depends upon the quality of the vehicle, i. e., quality in design and manufacture, and is thus closely connected with the initial cost. The "working life" further depends upon the condition in which the vehicle is maintained, and this in turn depends upon the driving and supervision, and the amount spent on renewals.

Having decided upon an estimated "working life" L, the next step is to consider by what method the initial cost should be spread over the period decided upon—in other words how the depreciation should be written off year by year. Three methods at least warrant consideration, namely:

1. To divide the capital outlay C, by the number of years at which the "working life" L, is estimated and charge the quotient against each year's working costs.
2. In the first year to write off a high percentage of the cost; in the second and succeeding years to write off the same percentage on the diminished value, that is, the balance left after deducting the previous year's depreciation.
3. To divide the capital outlay C, less residual value, R, (that is the estimated value of the vehicle at the end of its "working life") by the number of years, etc.

In each method, renewals and repairs, as they occur, are charged against "general running expenses." The first method cannot of course be recommended where any degree of accuracy is required. The second method is perhaps financially the soundest if it be desired to ascertain from one's books the actual realizable value of the vehicle at any moment. Although this method gives a fairly true result in the end, it has the objection that in its earlier years the cost of the service is overloaded.

The third method, expressed by the formula $\frac{C-R}{L}$, where C = capital outlay, R = residual value, and L = the estimated years of life, is that recommended as being the most practical and accurate method. The only observation necessary on this method is one dealing with the reconsideration of L at a later period. When the life of a vehicle is reconsidered, the unexpired capital outlay should be taken as the basis for the revised charge for depreciation. Thus suppose $\frac{C-R}{L} = \frac{500-50}{5}$, the annual depreciation being £90; by the end of two years the capital outlay would have been written down to £320. If the estimate of life be then revised and extended to seven years in all, with five more to run, then $\frac{C-R}{L} = \frac{320-50}{5} = £54$ annual depreciation.

Obsolescence is a factor which has to be considered, as it is by no means improbable that some combination of circumstances may render it desirable to dispose of a particular vehicle before it is really worn out. From a strict accounting point of view obsolescence may not be depreciation, but the factor is at least of sufficient importance to "round up" any percentage that may be determined by other considerations, and if, in the future, by perfecting the machines their ordinary working life can be reckoned as longer than it is at present, obsolescence will become of more importance, for a machine which is still quite efficient mechanically may be rendered uneconomical by the introduction of improved types. When such time arrives it may be prudent to make provision under this head, which while not strictly proper to depreciation may very conveniently be connoted.

There remains one other detail for consideration, namely, the treatment of small additions to plant. The effective life of the additions may or may not be coterminous with that of the vehicle, and any attempt to bring their depreciation within the scheme for the depreciation of the vehicle itself would cause complications which it would not be worth while to incur. The practise recommended is to regard such small additions as chargeable to maintenance, which, in effect, means writing them off at 100 per cent. in their year of purchase.

MOTOR TRUCK WHEELS.

The paper contributed by Arthur J. Slade on "Motor Truck Wheels," set forth that the author had suggested to the commercial car wheels division of the standards committee that in the standardization of metal wheels, along lines similar to the standardization of wood wheels, certain practises, as to material design, should be recommended for the benefit of the motor truck designer, and that while the suggestion was not approved it was met by the proposal that a paper be presented to the meeting with a view to bringing out available information as to suitable materials and designs for truck wheels, through those members best qualified to express themselves on the subject with authority.

After considering the development of wooden wheels and early metal wheels and the service to be obtained from them, the paper was as follows:

It will be noted that comparatively few well known truck builders in this country are at present using metal wheels and those who are using them have not previously used wooden wheels. There is one notable exception, however, the Pierce-Arrow Motor Car Company, on some of whose trucks I have recently seen cast steel wheels, although since the introduction of the Pierce five-ton truck on the market wooden wheels have been standard. It is hoped the engineers of that company will give us the benefit of their experience and their reasons for making this change.

The vast majority of motor truck manufacturers, including those whose product dates back to the beginning of the motor truck industry in this country, have used wooden wheels consistently, improving their design from time to time, but not abandoning a material for wheel construction which has on the whole proved entirely satisfactory.

Through the courtesy of Mr. George R. Wadsworth, member of this society, I have been furnished with reports on the mileage and condition of the wood wheels on a large group of gas trucks of three, four and five-tons capacity, which show that in some cases the mileage covered approaches closely to 70,000. On the assumption that the tire mileage secured on these trucks is 10,000 miles a tire, this would mean that some of the wheels have been subjected to six tire changes. The report states, regarding these wheels, that "they were all in first class condition and not a moment's inconvenience or delay has been caused by them and there is not the slightest indication of trouble in the near future." These wheels, it is scarcely necessary to say, are of modern design, are accurately constructed of suitable material, and are carefully inspected for conformation to the accepted S. A. E. motor truck wheels standards. The contention that wood wheels get out of round and present difficulties in tire application does not seem to be substantiated in this case.

As pointed out in papers on wood wheels, presented by Mr. Bert Morley and Mr. C. B. Hayes at the January, 1912, meeting of this society, there is no question as to the adequacy of the supply of wood for wheel manufacture. The experience of many of our members with wood wheels on motor trucks, extending over periods of years, indicates that the truck manufacturers in this country are not being forced by necessity to adopt metal wheels, so that if the truck manufacturer who has been using wood wheels satisfactorily for many years is to be influenced to adopt a metal wheel, it is essential that he should be shown that some practical advantage would be gained by the change.

When this society visited our British fellow engineers, several members of the American party made inquiries regarding the service rendered by metal wheels, in both England and France, and the results of the investigation were set forth in a short report which I made to the society at the January, 1912, meeting. Briefly, it was found that cast steel wheels were being used in England in a variety of forms. Also that structural steel wheels were preferred by some. Further, that the consideration of wood wheels had not been abandoned, even by those using steel wheels as a standard, and that some truck manufacturers preferred wood to metal, and used the former as standard. In France the wood wheel appeared to be the standard to the practical exclusion of metal wheels.

More recently Mr. L. C. Freeman, a member of this society, submitted a paper on "Tendency of Foreign Motor Truck Design" at the January, 1913, meeting in which he made the fol-

lowing statement: "While cast steel wheels seem to give very good results under certain conditions, they do not appear to be a universal panacea for all wheel troubles One user who has operated a great many trucks of many different makes said that cast steel wheels were all right until the tires wore thin. In this statement I think there is food for a great deal of thought. A built-up wheel of structural steel was giving him excellent service and almost no trouble." Doubtless some of our British fellow engineers present at this meeting can supply us with up-to-date information on the status of the metal and wood wheel in Great Britain.

At the present time there is undoubtedly a general effort being made by manufacturers of parts for motor trucks to add metal wheels to their product: and with the exception of one manufacturer, who proposes to build wheels of malleable iron, all of them are building their wheels of cast steel.

What, then, are the specific advantages offered by metal wheels which should influence a motor truck designer to specify metal construction rather than wood? The advantage must be such that it can be proved to the purchaser of the truck that he will secure an actual financial gain by the change which the engineer proposes, because to the purchaser the prime questions are the expense of operating and maintaining the truck over a period of years and the earnings or savings which the vehicle will effect. Theoretical considerations, unless borne out and proved in practise, are unavailing. Practical service conditions count with the hard-headed business man—not laboratory or experimental tests and calculations.

First, it is claimed by one of our members, who is chief engineer of a company about to place cast steel wheels on the market, that: "It is now conclusively proven that there is a distinct saving in tires on steel wheels. Some of the largest tire manufacturers guarantee as much as 30 to 40 per cent. longer life on steel than wood." Inquiry made of the leading tire manufacturing companies, verbally or by letter, has failed to verify that statement. The opinion of several tire company officials seems to be personally in favor of metal wheels for the one reason that they are likely to be made more accurately to size, but the tire companies positively decline to guarantee an added mile or to even express the opinion that added mileage can be expected.

As to the question of accuracy of workmanship, it is entirely feasible for the wood wheel manufacturers, under the present S. A. E. standards, equipping the wheels with S. A. E. bands, to work within the necessary tolerances and provide wheels which will have the accuracy required. Accuracy in workmanship is a question of care in construction and careful inspection and the manufacturer who insists upon accurate wood wheels conforming to S. A. E. standards has no trouble in securing them.
